FIAT LVX
MDCCCLXVIII
EX LIBRIS

No. 3496. NOVEMBER 21, 1919. Vol. LXVIII.

JOURNAL OF THE ROYAL SOCIETY OF ARTS

CONTENTS.

Published every Friday. *Price to Non-Fellows, 6d.*

LONDON:
Published for the Society by G. BELL & SONS, Ltd., York House, Portugal St., W.C. 2

REGISTERED AS A NEWSPAPER.

JOURNAL

OF THE

ROYAL

SOCIETY OF ARTS

VOLUME LXVIII.

FROM NOVEMBER 21, 1919, TO NOVEMBER 19, 1920.

LONDON:
PUBLISHED FOR THE SOCIETY BY G. BELL & SONS, LTD.,
YORK HOUSE, PORTUGAL STREET, LINCOLN'S INN FIELDS, W.C. 2
1920

LONDON:
PRINTED BY WILLIAM CLOWES AND SONS, LIMITED,
DUKE STREET, STAMFORD STREET, S.E. 1, AND GREAT WINDMILL STREET, W. 1.

Journal of the Royal Society of Arts.

No. 3,496. VOL. LXVIII.

FRIDAY, NOVEMBER 21, 1919.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

ONE-HUNDRED-AND-SIXTY-SIXTH SESSION, 1919-1920.

NOTICES.

NEXT WEEK.

WEDNESDAY, NOVEMBER 26th, at 4.30 p.m. (Ordinary Meeting.) H. B. MORSE, LL.D., late Statistical Secretary, Inspectorate-General of Chinese Customs. BYRON BRENAN, C.M.G., late H.B.M. Consul-General, Shanghai, will preside.

Further particulars of the Society's meetings will be found at the end of this number.

EXAMINATIONS.

The results of the examinations held in April and May-June this year have been printed and sent to all centres. The results contain the names of all candidates awarded certificates in the three stages of the examinations, and also the list of the winners of the silver and bronze medals in Stages II. and III.

INDIAN SECTION.

A meeting of the Indian Section Committee was held on Monday, November 17th. Present: Sir Charles S. Bayley, G.C.I.E., K.C.S.I., in the chair; T. J. Bennett, C.I.E., M.P.; D. T. Chadwick, I.C.S.; W. Coldstream; Sir Frederic W. R. Fryer, K.C.S.I.; Sir Henry Evan M. James, K.C.I.E., C.S.I.; Sir Charles Campbell McLeod; Sir John O. Miller, K.C.S.I.; Sir Prabashankar Dalpatram Pattani, K.C.I.E.; and N. C. Sen, O.B.E.; with G. K. Menzies, M.A., Secretary of the Society, and S. Digby, C.I.E., Secretary of the Section.

The Council have appointed Brigadier-General Sir Percy M. Sykes, K.C.I.E., C.B., C.M.G., a member of the Committee.

PROCEEDINGS OF THE SOCIETY.

FIRST ORDINARY MEETING.

Wednesday, November 19th, 1919; Sir HENRY TRUEMAN WOOD, M.A., Chairman of the Council, in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Adams, Thomas Gallon, Newcastle-upon-Tyne.
Aitchison, Captain Leslie, R.A.F., D.Met., B.Sc., Birmingham.
Ann, Alfred Edward, M.Inst.M., London.
Annable, Henry William Coupe, Egham, Surrey.
Ardley, William Guy, St. Albans, Herts.
Atkinson, George Scott, B.Sc., Flixton, Lancs.
Austin, John Corneley Wilson, F.A.I.A., Los Angeles, California, U.S.A.
Baker, John Harry, London.
Bangs, Clare W. H., A.M., Huntington, Indiana, U.S.A.
Barker, William John, London.
Barr, Peter Rudolph, London.
Barrow, Henry, Westcliff-on-Sea, Essex.
Batliwala, Dhunjeebhoy Framjee, Bombay, India.
Battra, Ram Lal, B.A., LL.B., Simla, India.
Beere, William James Edward, London.
Betterton, Walter, London.
Bevan, Charles C., Eccles, Manchester.
Bjerknes, Professor V., Bergen, Norway.
Blackbourn, Lionel Alfred, London.
Blake, William Payne, Boston, Mass., U.S.A.
Bland, Frederick, M.I.Mech.E., Sheffield.
Boucaut, Gordon Lorraine Penn, Adelaide, South Australia.
Brooks, Willoughby Lewis, London.
Bruce, Joseph, London.
Bunge, Julius Henri Otto, Greenford, Middlesex.
Burtwell, George J., London.
Cain, Charles Alexander, J.P., Welwyn, Herts.
Callaghan, Walton John, Sydney, N.S.W., Australia.
Campbell, Robert Hunter, London.
Cathcart, William Hutton, Renfrew.
Chapman, A. Chaston, F.I.C., London.
Cheng Fu Wang, Penchi Hu, Southern Manchuria, China.
Chintamani, Hon. C. Y., Allahabad, India.
Churchill-Smith, Major James, A.I.F., London.
Clarke, Albert James George, Sydney, Australia.
Clinton, Cecil H., Kingston, Surrey.
Clough, Fred., Dumfries.
Cole, Miss R., Ilford.
Connolly, Joseph, Pendleton, Manchester.
Coote, Wilfred Arthur, Sydney, N.S.W., Australia.
Dean, Stephen Woodhouse, London.
Douglas, C. C. Brown, London.
Drew, Verney, Thornton Heath.
Dunlop, Clive V., Sydney, N.S.W., Australia.
Edwards, Henry, M.Inst.M.M., Caversham, Reading.
Farquharson, Arthur Wildman, Kingston, Jamaica.
Fletcher, Stephen Baldwin, Stornaway.
Foster, Frank Geden, Selby, Yorks.
Fowler, John S., London.
French, James Weir, B Sc., Glasgow.
Gandhi, N. P., M.A., B.Sc., A.R.S.M., Benares, India.
Gawley, George J., A.I.E.E., Fleet, Hants.
Gibson, Professor Charles Stanley, O.B.E., M.A., F.I.C., Cairo, Egypt.
Gierløff, Christian, Christiania, Norway.
Goodenough, Frederick Craufurd, London.
Gordon-Cameron, E., A.M.I.E.E., Bombay, India.
Gregg, Alfred W., M.Sc., Chicago, Ill., U.S.A.
Grosch, Direktor H., Christiania, Norway.
Hall, Rev. Henry Wardale, Lincoln.
Hall, Horace Campbell, M.Inst.Met., F.C.S., Chellaston, Derby.
Hampshire, Frederick William, Michleover, Derby.
Hands, Henry James, Moseley, Birmingham.
Haslam, William John, Harrogate, Yorks.
Hawkes, Engineer-Commander Charles John, R.N., London.
Hayes, Henry G., A.M.I.A.E., Weston-super-Mare.
Hayles, Robert B., Andover, Hants.
Headicar, B. Mason, London.
Hethey, Axel, B.Sc., A.R.S.M., London.
Houghton, William Sherwood, Victoria, Australia.
House, Charles E. G., A.R.C.Sc., London.
Howie, William John, London.
Hughes, Frederick, Belfast.
Hughes, Gibbard, M.B.E., Great Missenden, Bucks.
Instone, Arthur Brian, M.Inst.Met., Coventry.
Ionides, Alexander Constantine, Junr., London.
Ireland, Arthur James Thomas, A.M.I.A.E., London.
Jeffries, Zay, D.Sc., Cleveland, Ohio, U.S.A.
Johnson, Joseph M., M.P.S., M.Inst.Met., Harborne, Birmingham.
Johnson, William, Harborne, Birmingham.
Jones, Dudley A., South Farnborough, Hants.
Jones, Horace, Coventry.
Keilhau, Direcktor Dr. Wilhelm, Christiania, Norway.
Kenyon, Alexander, Moss Side, Manchester.
Kerr, James Sinclair, Eston, Yorks.
Kilner, Dr. Frank, B.A., Ph.D., Harrogate, Yorks.
King, J. Foster, Glasgow.
King, Captain Renshaw Weyland Hugh, A.I.F., London.
Kingsmill, C., Sydney, N.S.W., Australia.
Kipling, Herbert Spencer, Birmingham.
Klaveness, A. F., Christiania, Norway.
Knight, Lucien Lamar, M.A., LL.D., Atlanta, Georgia, U.S.A.
Kotval, Kavasji Palanji, London.
Lackie, William Walker, Glasgow.
Lander, Charles, London.
Law, John Stephen, Sydney, N.S W., Australia.
Leach, Frederick Beresford, London.
Leete, Ernest, Wadhurst, Sussex.
Lilley, Herbert Henry, Bombay, India.
Limericke, Y. Anthony Joseph, LL.B., F.C.I., Java, Dutch East Indies.

List, Francis Paul, Luxembourg.
Little, Captain Roy J., R.A.V.C., London.
Lloyd, Frederic, Sheffield.
Lock, Francis Michael, Lieutenant A.F.C., Allandale East, South Australia.
McCormick, James, Malton, Yorks.
Macey, Miss Mabel, London.
McLeod, Robert James, West Drayton, Middlesex.
McMillen, Hugh Harris, Moreland, Victoria, Australia.
Mahamadi, Saeed S., M.B., Ch.B., London.
Mandroo, Labho Ram, Karachi, India.
Maynard, Edwin, M.D., London.
Mayo, Charles Robert, M.I.Mech.E., London.
Mellor, Rev. Percy C., East Grinstead.
Membrey, James Stanley, Northcote, Victoria, Australia.
Milward, William Francis, Sheffield.
Minta, Rev. William Robert, Mus.Bac., Ulverston, Lancs.
Mitchell, Lieut. George Joseph, A.R.C.A., Southport, Lancs.
Morgan, Sir Herbert Edward, K.B.E., London.
Needham, Harry Algernon, Erdington, Birmingham.
Newling, R. S., Simla, India.
Notman, Arthur, Arizona, U.S.A.
Notman, Howard, Brooklyn, New York, U.S.A.
O'Donel, Major Manus Basil Hugh, O.B.E., London.
Offer, M., Montreal, Canada.
Ogilvie, Alexander, C.B.E., London.
Parish, Neville B., Bikaner, India.
Parsons, J., Hong-Kong, China.
Paterson, Thomas Watson, A.M.I.A.E., Liverpool.
Paton, James Lampard, Cottesloe, Western Australia.
Pizzey, Albert Edward Russell, Bristol.
Price, Frederick Charles, Bowden, Cheshire.
Rankin, John, Glasgow.
Rees, Eric, F.R.M.S., Swansea.
Reeve, Harold F., Swansea.
Reilly, F. Myles T., Worthing, Sussex.
Rhodes, John Henry, Leigh, Lancs.
Richardson, Major John Foulkes, A.I.F., London.
Riches, H. Cecil, Cardiff.
Ridge-Beedle, P. D., Glasgow.
Ritchie, Gerald, London.
Roberts, Harold White, Manchester.
Robinson, Lieut. Gerald Hercules, A.I.F., Sydney, N.S.W., Australia.
Rock, Claude William Dunmore, Launceston, Tasmania.
Rothwell, Herbert, London.
Sain, Kanwar, M.A., Lahore, India.
Satow, Konji, B.Sc., Tokyo, Japan.
Shardlow, Howard W., London.
Shedden, Duncan Jones, Birmingham.
Sircar, J. K., F.R.H.S., Bombay, India.
Skidmore, George R. J., Gateshead-on-Tyne.
Sloan, Alexander, Cumberland, Maryland, U.S.A.
Smith, Lieut. Victor Charles, A.I.F., Brunswick, Victoria, Australia.
Snowell, A. E., Purley, Surrey.
Speakman, John Dean, Cambridge.
Spiers, Arthur Hood, M.A., Twickenham.
Spink, John Marshall, London.
Tennyson, Charles B. L., C.M.G., London.
Thomson, George, Junr., Aberdeen.
Tidswell, F. E., London.
Tofts, Captain Crozier Fullerton, Bombay, India.
Tolputt, Herbert, Sheffield.
Tovell, Major Raymond Walter, A.I.F., Melbourne, Victoria, Australia.
Valentine, Charles Robert, Shimoga, Mysore State, India.
Vegas, Santiago, Caracas, Venezuela.
Vig, Christian, Christiania, Norway.
Wadge, John Percy, East Molesey, Surrey.
Warren, H. W. Hugh, A.M.I.E.E., Coventry.
Washburn, Professor E. W., Ph.D., Urbana, Illinois, U.S.A.
Watson, George S., Sheffield.
Watt, Charles, A.M.I.A.E., Malvern, Worcestershire.
Webley, Lieut. Ivan Schroder, A.F.C., London.
Webster, Captain Frederick, M.C., Assoc.M.Inst.C.E., Hawarden, Chester.
Wibberley, Rev. Brian, Mus. Bac., Perth, Western Australia.
Wilson, Frank Denham, Melbourne, Victoria, Australia.
Wimalasurendra, Devapoora Jayasena, A.M.I.C.E., A.M.I.E.E., P.W.D., Ceylon.
Wire, Arthur C., B.A., London.
Wood, Reginald Arthur, Lieut. A.I.F., Perth, Western Australia.
Woodward, Joseph J., London.
Worthington, Captain Percy, R.A.F., Bexley, Kent.
Young, Arthur Primrose, A.M.I.E.E., Kenilworth.
Young, George Washington, New York City, U.S.A.

The CHAIRMAN delivered the following

ADDRESS.

Just five years ago Sir Thomas Holdich, in the address which he delivered as Chairman of the Council, three months after the beginning of the war, was able to say that even in those dark days the Society could commence a new session "with good hopes, fair prospects and no regrets." After the five years of trial and tribulation through which we have passed, it is good to be able to repeat the same courageous hope for the future, the same fortunate retrospect of the past. Five years ago we none of us could foresee what were the prospects of our Society, or of any of the institutions of the country, or even to estimate the chance of its survival. For a time the future looked rather black; but the set-back was only temporary, we rapidly revived, and we are now in as sound and prosperous a condition as ever in our long history. Naturally we have suffered, and shall go on suffering, from causes

beyond our control. High prices and depreciated currency affect institutions as they do individuals, but these are difficulties we share in common with the rest of the nation, and as the nation will surmount them, so will the various units of which the nation is composed.

As it was the need for the better organisation of industry that led to the foundation of this Society more than a hundred and sixty years ago, and as the Society has ever since its foundation taken its full share in the promotion of industrial progress, it has occurred to me that the great problem whose solution is the most pressing task the country has in hand, the Reconstruction of Industry, might well form a suitable subject for our consideration this afternoon.

In the two interesting and suggestive addresses which Mr. Campbell Swinton delivered to the Society during his term of office, he dealt largely with the relations of science and manufactures; but the theme is a wide one, and affords ample scope for further discussion.

Now we are very apt, in considering present conditions, to talk about them as unprecedented, as surpassing all human experience. In a sense that is unhappily true; but humanity has had evil experiences before, though we are fortunately not endowed with a capacity for realising the horrors of past and happily forgotten disasters. The misery, the suffering, the sorrow in England during the Black Death of the fourteenth century certainly (if the relative numbers of the population be considered) far exceeded all we have endured in the past five years; while if we may search in vain for a parallel to the actual atrocities of a war to which has been directed all the knowledge accumulated by centuries of scientific work, yet the threatened results of past wars have been regarded with apprehension equal to any we now entertain as to our future prosperity.

Perhaps, then, it may be worth while, before discussing present prospects, to look back at the last period of the country's peril, the conclusion of the Napoleonic wars, and to see whether there may not be some lessons to be gathered from the past which may serve as guidance for the future. The foundation of the Society was almost contemporaneous with the beginning of the Seven Years' War (1756), and the recovery of English trade and commerce after the Peace of Paris (1763) has its lessons for us now. I will not, however, ask you to go so far back as that, but merely to consider the conditions just a century ago—say, in 1819, the year in which Queen Victoria was born and James Watt died. Then, as now, England had just rescued Europe from the arrogant domination of an unscrupulous autocrat. Then, as now, she was suffering from the losses imposed upon her by the execution of the task, and was well-nigh exhausted by her efforts. She was suffering, too, from internal dissensions and divided councils. Yet she bent to the task of recovery as she bent to the task of conquest, and with a like success. She gained small profit from the results of war, as she will gain little now. Yet in a few years time she was stronger, richer, more prosperous than she had ever been before. Her commerce was extended, her industries increased. She started on that era of commercial prosperity which lasted until Germany, impatient at the slowness with which she was filching from us our trade and our consequent prosperity, precipitated the war which wrecked her own prospects, and from which if we are wise we shall make a fresh start in our industrial progress.

In 1819 the impulse of the Industrial Revolution was dying out. As to the precise period over which the revolution extended, everybody is free to form his own opinion. As good landmarks as any other we may take the dates of Watt's improvement of the Newcomen engine (1754) and of Stephenson's application of Watt's engine to locomotive purposes (1825). At all events by the end of the Napoleonic wars the first period of the industrial revolution was completed. The factory had taken the place of the workshop and steam-power had superseded, for the driving of all machinery, the power of men and animals. But while the use of the stationary engine had become general, the application of steam for locomotive purposes had yet to come. It was this special application of it and the enormous facilities it provided for the transport of persons and commodities which have changed all the conditions of civilised life, and have most profoundly modified its character.

The present year has seen the crossing of the Atlantic by air. In 1819 it was first crossed by a steamer, the "Savannah," partly under steam and partly under sails. It appears to have been fourteen years before another attempt was made, and in 1833 the "Royal William" came from Quebec to London under steam alone. Yet another five years (1838) and the passenger service to America was regularly inaugurated by the voyage of the two steamers the "Sirius" and the "Great Western," which crossed the Atlantic practically simultaneously.

The point in its development which steam navigation had reached a century ago may be judged from the fact that the first time a steamer made a sea voyage in European waters was in 1815, when the "Argyle," renamed the "Thames," made an adventurous and very risky journey from the Clyde to the Thames. The feat was anticipated in America seven years earlier, in 1808, when Stevens, the eminent American engineer and inventor, took the "Phœnix" under steam from the Hudson River to the Delaware, 150 miles or so of the voyage being at sea. In 1818 (just over the century) the "Rob Roy" started to trade between Glasgow and Belfast, and after carrying mails and passengers "with great punctuality" for two years she was sent round to Dover to take part in starting the cross-Channel traffic, the beginning of which must therefore be dated as about 1820.

We have not yet reached the centenary of steam locomotion on land. This must be dated 1925, a hundred years after the opening of the Stockton and Darlington Railway in 1825, though it must be remembered that in 1808 Trevithick had an experimental railway on the ground now occupied by Euston Square. Trevithick was the real inventor of the locomotive, the high-pressure engine with a tubular boiler, but his engine was only an experimental one, and had to be greatly improved by Stephenson and others before it was really fit to accomplish useful work.

The current year may certainly claim to be a telegraphic centenary, for it was in 1819 that Oersted discovered that a compass needle was affected by a neighbouring galvanic current, but it is just over a hundred years since the first practical electric telegraph was completed. In 1816 Ronalds had his apparatus at Hammersmith transmitting signals and complete messages along eight miles of wire, and no doubt the distance might have been considerably extended. Ronalds used frictional electricity, and it might be a little hazardous to attempt an estimate of the distance to which, with the appliances then available, signals could be sent. Probably that distance was less than the inventor thought, but this was a question to be answered by further experiment. The further experiment was never made. Ronalds, having completed his apparatus, invited the Admiralty to inspect it, and the answer he received remains for all time the record example of official ineptitude.

"Mr. Barrow presents his compliments to Mr. Ronalds and acquaints him ... that telegraphs of any kind are now wholly unnecessary and that no other than the one now in use will be adopted."

Let us hope that Sir John Barrow did not himself write the letter sent in his name, for it has over-shadowed the remembrance of much useful official work, and he is known to posterity chiefly as the man who prevented the establishment of the first electric telegraph.

A hundred years ago the great industry of coal-mining was in a state of rapid development. The demand for coal was increasing at a cumulative rate. First came the demand for fuel for the boilers of steam engines. Next, the substitution of mechanical for animal power caused great multiplication of machinery, and the iron needed for the construction of the machines necessitated for its production the consumption of coal. Then the extending use of gas for lighting involved the supply of large quantities of coal, to say nothing of the steady increase of the domestic consumption of coal.

The demand was met by the opening up of fresh coalfields and by carrying the workings to greater depths. In both cases the extension was rendered possible by the knowledge provided by the young science of geology. It was the information contained in the maps which the Society in 1815 helped William Smith, the "Father of British Geology," to publish, that enabled the coal measures to be located with certainty beneath the overlying strata.

The increased depth and the extension of the workings added greatly to the difficulties and dangers of mining coal, and these were met, not only by improved ventilation and by better mechanical arrangements for bringing the coal to the surface, but also by the Safety Lamp, an invention of which it may be sufficient to say here that it was probably (almost certainly) the earliest instance of the application of pure scientific induction to the provision of a desired practical result.

It was mainly in the great textile industry that the influence of the Industrial Revolution was most apparent. Indeed, it was mainly in this industry that the changes were effected which justified the name of revolution. In principle all these changes may be said to have been completed before the period with which we are dealing. That period was one of steady and rapid development, not of considerable or organic change. The time had come, or nearly come, when cotton was "opened, cleaned, spread, carded, drawn, roved, spun, and

weaved" by machinery. After that it was a mere matter of improvement in detail and general development.

A century ago it may be said that the foundations of chemical industry were only being laid. The science of chemistry was, indeed, only gradually being systematised, and was in no condition to hold out much of a helping hand to industry. The problem of making soda from sea-salt, which had exercised many minds and ruined some of those who attempted to find a solution, was solved by the Frenchman Leblanc in 1792, but though the great alkali manufacture was the ultimate result, it took many years to bring about its establishment. Before alkali became an article of manufacture, the makers of glass, soap, etc., had had to rely on natural supplies of potash and soda—the "fossil fixt alkalies" for which this Society offered prizes for many years—and on alkali obtained from the ashes of plants. (It is interesting to note that the limitation of the supply of potash caused by the war resulted in a temporary revival of the Irish kelp-burning industry.) Leblanc's process was introduced into England on a small scale by Losh in 1814, and on a commercial scale by Muspratt in 1823, but it was long before it was established here. Charles Tennant, at the instance of James Watt, had in 1799 utilised Berthollet's discovery of the bleaching powers of chlorine (discovered by Scheele in 1774), and was making "bleaching powder" by treating slaked lime with chlorine. Humphry Davy had already (1807) completed those researches into the nature of the alkalies which served as the foundation later on of many important industries. These were carried out with the great electric battery at the Royal Institution with which he obtained the "voltaic arc." He was also laying the foundations of agricultural chemistry. As regards dyes, we were much in the same condition as when the Society started its career by offering prizes for madder and cobalt, and another generation had to pass before we got, in Perkin's synthetic dyes, any substitute for the ancient materials which served our forefathers.

On the whole, those industries which are now dependent on chemical methods, such as brewing, tanning, distilling, making vinegar, glass and soap, or those wh ch were concerned with such chemical products as were then manufactured, alum, sulphuric acid, gunpowder, copperas, were carried on in the old empirical fashion, and were only beginning to adopt scientific procedure or trying to devise methods for its application.

I do not mean to suggest that this very brief and incomplete sketch of our industrial conditions a century ago affords material for drawing any useful lesson at the present moment, but I am convinced that if it were possible to bring before you in greater detail the history of the expansion of British industries during the first quarter of the nineteenth century, and of the development of the inventions on which that expansion was based, you would realise one outstanding fact, that all our progress was accomplished by individual action, not by State organisation or control. The period to which I am referring may be regarded as the one during which industrial England made the most rapid progress and underwent the greatest changes. In the succeeding period the progress was steady and perhaps greater, but the rate was not quite so speedy, and the changes in means and in methods, though their cumulative effect may have been greater, were less sudden, less violent. Scientific knowledge increased, it was more carefully organised and more systematically applied to industry. The result was not only the modification of existing procedure, and the substitution of new for old methods, but the rise of absolutely new industries founded on scientific discoveries.

This triumph of system and of organisation leads us to demand fresh system and more organisation, and as the German nation grew prosperous and rich by calling in State organisation to the aid and supervision of its industry and its commerce, we English folk—ever distrustful of our own methods—have taken fright and are calling for similar help. This may be right or it may be wrong; it may be wise or it may be foolish. Probably there are some cases in which State control is essential, others in which it is disastrous. At all events, there can be no harm in pointing out that it was not by State-guided organisation that our grandfathers and great-grandfathers made England the workshop and the emporium of the world. No one would suggest that the methods of a hundred years ago are wholly applicable nowadays. They are not. Still, it cannot do any harm for us to realise what they were. We may learn somewhat from them though we certainly cannot go back to them. Theirs was a time of individual, unorganised effort, of struggle against ignorance and the prejudice arising from ignorance. In their days the chief function of the State in its attitude towards invention was

steadily to apply the brake to the wheels of progress, and this function it persistently fulfilled. If an inventor offered his invention to Government, he was snubbed; if he went to Parliament for an act granting facilities indispensable for his invention, he was opposed; if the works he set up to carry out his invention annoyed his neighbours, or affected their crops, he was promptly (perhaps not unreasonably) driven away—and so on. Of course, the State only represented embodied public opinion, and public opinion was adverse to novelty. Now we run to the other extreme: we are credulous, and accept all new-fangled inventions at their face value, often very different from their intrinsic worth. Perhaps, after all, the wisest view to take is to admit that it is the nature of man to swing from one extreme to another like a pendulum, and to remember that if the pendulum swings to and fro, making no advance, still all the same the clock goes steadily on.

Whatever may be the comparative value of England's contributions to the advance of pure science in the early days of its growth—and the work of Newton, Boyle, Hooke, Cavendish, Priestly, Davy, Dalton, Faraday, compares not unfavourably with that of Galileo, Lavoisier, Volta, Scheele, Huyghens, Kepler, Descartes, Copernicus, Richter, Berzelius, Avogadro, Laplace, Euler, Ampère—there can be no question that it was in England, or rather in Britain, for Scotland contributed her share, that science was first utilised for the benefit of industry, and that the applications of science were regularly developed until England became the workshop of the world. It was here that the steam engine was perfected and utilised first for supplying power to all forms of stationary machinery, then for purposes of transport over land and sea. It was here machinery driven by mechanical power took the place of implements and appliances worked by human or animal power, first in the great textile industry, then in every form of manufacture by which human needs are now supplied. It was here that chemical products, often devised in other countries, were developed on a manufacturing scale and by improved methods, until the commerce resulting from our industries eclipsed that of every other nation. For a time we had the field almost to ourselves, but naturally we soon had our rivals. America was perhaps the earliest. In the development of the marine steam engine she took an important part, and when at a somewhat later epoch she became a great manufacturing country, her factories made more rapid progress than our own.

The industrial development of Germany hardly dates back for more than a generation, but the marvellous rapidity with which she assimilated the accumulated knowledge of the world, and the concentrated energy with which she devoted herself to the task of developing her resources, soon placed her ahead of all the other nations in the field of scientific industry.

In the brilliant address which Sir Dugald Clerk gave us four years ago in this room, he demonstrated that it was not the German's superior intellectual capacity but his power of adaptation, his energy in working out the original ideas of others, his unlimited industry, his unwearied and patient application that had been the cause of his success. That success fully deserves our admiration, but it does not justify the humiliating subservience with which before the war we regarded his methods and his system. We acquiesced meekly in his superiority, and accepted his own boastful estimate of his own merits. He told us that he had beaten us in the pursuits of peace, and that he was going to knock us out once for all in war. We may admit now that we believed both statements, but when it came to the practical trial we found out that his ultimate conclusion was incorrect, and now we are going to show that his original statement was not necessarily to be accepted without demur.

There need be no hesitation in admitting that before the war Germany had gone far ahead of us in the application of chemical science to industrial purposes. It was the primary object, the first duty of the chemist to discover what things are made of, what the constituent elements are of which substances are composed. Having by generations of study achieved a mastery of analysis, he was led on to synthesis, the attempt to form new combinations, or to reproduce natural combinations, of the materials he had separated. Among the earliest labourers in this direction the most striking success must be credited to Perkin (though he was working under the direction of the German, Hofmann), who tried to manufacture artificial quinine, and produced a new colouring material.

On this discovery was based the great coal-tar colour industry, which, after being successfully carried on for a few years in this country, was bought up and transferred to Germany

where it formed the basis of the vast chemical industry which has been developed there in the last fifty years. How this development was effected is well known. Immense capital resources were devoted to it, the most skilful chemists were sought out, trained and paid to devote themselves to experimental research. No expense was spared in fitting laboratories or in pursuing lines of investigation often apparently unpromising. Definite objects of inquiry were selected and their investigation pursued until the object was obtained or proved unattainable, with the ultimate result that, as regards the dyeing industry, artificial productions have been substituted for natural materials, a host of new dyes have been devised and in certain cases the old materials have been actually manufactured by cheaper and more rapid means than the costly and slow processes of nature.

But the scientific investigations originally directed to the production of new and cheaper dye-stuffs, have had far-reaching effects in other directions. The same principles were applicable, and were applied, to other manufactures. To pursue the history would require a volume, and its discussion could only be usefully carried on by a skilled and experienced chemist. Perhaps no better subject could be selected for a course of Cantor Lectures than the industrial applications of synthesis, "the production synthetically —that is by the union of elements—of compounds previously obtainable only from natural sources." Some few of these have lately been described by Sir William Tilden, and a typical one may be mentioned as an example, the artificial production of ammonia by the combination of hydrogen with atmospheric nitrogen, and the manufacture of the nitrates required for explosives by causing the ammonia to combine with atmospheric oxygen, and thus converting it into nitric acid.

In this last-mentioned process we have an instance of the manner in which the Germans have employed the processes of industrial science to the manufacture of munitions of war. The real importance, however, of the process is, not that it facilitates the manufacture of high explosives, but that it provides the means of producing nitrates in large quantities, and at a cost which enables them to be employed as agricultural fertilisers, so that if it justifies the anticipations of its value expressed by competent authorities, it will be the final realisation of the prophecy made by Sir William Crookes just twenty-one years ago. In the address which he delivered at Bristol in September 1898, as President of the British Association, Sir William said: "The fixation of atmospheric nitrogen is one of the great discoveries awaiting the ingenuity of chemists," for though many attempts had been made "no process has yet been brought to the notice of scientific or commercial men which can be considered successful whether as regards cost or yield of product." In what were then regarded as visionary speculations, saved only from derision by the eminence of the speculator, Crookes showed that the future food supplies of the world depended on an adequate provision of nitrate of soda, a fertiliser practically then to be obtained only from the deposits of Chili saltpetre. As a popular illustration of the abundance of nitrogen, its present uselessness and its potential value, he told his audience that the Colston Hall in Bristol, in which he was then speaking, actually contained about twenty-seven tons of nitrogen, in the gaseous state worthless but in the form of nitrates of soda worth some £2,000. He indicated the method by which the problem was ultimately solved, the use of electricity generated by dynamos driven by water-power, and finally declared that "The fixation of nitrogen is vital to the progress of civilisation."

How the problem was first solved was described in the paper read before this Society in 1909 by Herr Sam Eyde, but despite all the improvements which have since been made, the nitrogenous fertilisers produced before the war, calcium nitrate and calcium cyanamide, were not of equal value with the nitrates of soda and potash, while their comparatively high cost was an obstacle to their extensive use. There appears to be every reason to believe that by the new process the cost of production has been greatly lessened. It is also stated that the economical working of the process does not depend on the use of water-power, and there therefore appears no reason why the manufacture should not be carried on in this country just as well as in Germany.

And there is room enough and to spare in this country, both for the introduction of new industries and the development of old ones. It is to be remembered that we have during the past five years initiated and completed a vast manufacture of war munitions. The time has now come when we have to utilise as best we can, for the purposes of industry and commerce, the factories set up for purposes of war.

The direction our labours have to take was well indicated by the excellent collection brought together at the British Scientific Products Exhibition which was held this summer in Westminster. This collection illustrated in a most forcible manner the progress which had been made during the war, and in spite of all the difficulties of the war, in substituting purely British products for numerous manufactured articles hitherto made exclusively or chiefly in Germany. The great and successful efforts which have been made to establish in England the manufacture of dyes are well known, and there is every reason to believe that in the future we shall be able, if not to supply all our own requirements, at least to compete on equal terms, in our own markets and in the markets of our Allies, with those rivals who once held a practical monopoly of this great industry. The Exhibition brought to public knowledge what was already known to scientific students, that similar efforts were being made to extend the influence of scientific knowledge in many branches of industry which had hitherto either been neglected in this country, or had been conducted too closely on the old empirical lines. It is certainly not true to say—as some enthusiastic advocates seem inclined to say—that science was ignored by British manufacturers. It was not. In certain trades—two for instance of the most important of all, the iron and steel manufacture and the great alkali trade with all its ramifications—scientific research was utilised to the full, while in numerous others it was gradually becoming more and more important. But our advance was much too slow. Our manufacturers were too reluctant to adopt new methods and to abandon old plant. They hesitated to pay enough to secure the services of highly trained experts. They were reluctant to risk capital in costly researches which might prove unsuccessful. They never dared to establish great laboratories, with highly paid experts in charge, for the business of investigations which might prove unprofitable. The result was that they were surpassed, often superseded, by their rivals in Germany and America, who did all these things, and their business was quickly drawn away, and passed into their rivals' hands.

We have had a rude awakening. The process seems to have been effective, for we have certainly realised our position. It remains to see whether we can improve it, and there seems to be no reasonable doubt that we can. So far as the application of science is concerned the nation is thoroughly aroused. The Government took the question up seriously very early in the war, and in the summer of 1915 it established a definite Department for Scientific and Industrial Research. A very clear and excellent account of the work and objects of the new Department was given to the Society in the interesting paper read last session by its Secretary, Sir Frank Heath, and the official record of its proceedings will be found in its annual report (the fourth) issued at the end of August last.

The formation of a Government Department of Scientific and Industrial Research was not received with unmixed satisfaction by the industrial world, especially by those who have a general mistrust of the Government Danai, even when they come, as in the present case, *dona ferentes*. This prejudice, however, is perhaps as unwise, though certainly more reasonable than that of our Socialistic friends who would turn over the control of all our industry to Government, and it is naturally felt —or at least expressed—chiefly by representatives of those great manufacturing firms who are already applying scientific research in their own businesses, and naturally prefer to retain the results for their own benefit rather than to share with their rivals the advantages of a larger scheme.

But whatever the opinions, biased or unbiased, of commentators, there can surely be little doubt that the experiment was a wise one, and well worth trying. It is too soon yet to look for big results, though eighteen research associations are already in existence and some discoveries of practical value have already been achieved. The Department has only recently organised itself, and this it has done extremely well, and in very practical fashion. The controlling body, Advisory Council as it is termed, is a committee of scientific experts, very similar to the committee of the Royal Society which managed the National Physical Laboratory until its recent transfer to the Government, and though it is nominally under the control of the "Lords of the Committee of His Majesty's Privy Council," that committee is believed to hold no meetings, so that it is for the special purpose an absolutely ideal body with the sole function of receiving an annual report.

It may reasonably be anticipated that the best part of the Department's work will be that carried out by the Industrial Research Associations which are being established in various trades. Whenever a trade forms such an

association and contributes sufficiently to its funds, the Department contributes an equivalent amount, up to a certain limit, leaving the disposal of the money (under certain reasonable conditions) in the control of a board appointed by the trade. It would appear, therefore, that the constitution of these associations realises what some astute educational expert said was the ideal of a State system of education, the maximum of Government money and the minimum of Government control. From the latest report it appears that a satisfactory response is being made to the offer. Many such associations are getting into work, and are already beginning to tackle various technical problems requiring scientific investigation. One remark may perhaps be permitted. It is not only the great industries, engineering, chemical and textile, that require scientific help. Many of our smaller trades want it just as much and are less able to get it. To them the new organisation should prove of the utmost value, and if trade jealousies can be avoided—as they should be—members of such trades should by joint action be enabled to obtain much useful knowledge they can hardly be expected to hunt out by individual effort.

The greatest problem, however, in industrial science—greater even than the substitution of swift and economical methods of manufacture for the slow and cumbrous processes of nature—is the provision of new sources of power. For ages man had to rely on his own strength aided by the powers of the few animals he had subordinated to his service. The source of all his available power was the food consumed by himself and his cattle. Gradually he learned to utilise some natural forces, the force of the wind and that of moving water. Of these the wind only was of much importance, as it afforded for centuries the only motive power by which his ships were driven over the seas. On land the wind was of small service, though wind-mills are very ancient, and certainly were used for grinding corn by the Romans and probably by earlier peoples. Water-mills for the same purpose were perhaps a little later, though there are references to them in classical writers. Whether, except for grinding corn, and possibly other materials, any mechanical power was used until quite modern times may perhaps not be easy to say. I doubt whether there is any application much older than the tilt hammer used by the Sussex and other iron-makers. As time went on, wind and water-power came in for various purposes, first pumping, and later for driving heavy machinery, saw-mills, rolling-mills and the like.

Then, two hundred years ago, the construction of the first practical steam engines enabled the power of heat to be utilised for mechanical purposes, and as coal was the best and most abundant fuel, coal became the great source of the energy required. Till recent years, except in certain localities where timber was abundant, coal has remained the one available fuel for the supply of the heat-engine, but the utilisation of oil now provides a supplementary source of the highest value. The supplies, however, of coal and oil are not illimitable, and the increasing demand for both is bringing nearer and nearer the not very distant date when those supplies will be exhausted. Oil in greater or smaller amounts is found all over the world. Opinions seem to vary as to the total supplies available, but there seems good reason to believe that vast amounts will be forthcoming from new fields as well as from fields already known.

In the meantime the search for fresh sources of energy occupies the earnest attention of many of our wisest minds, and though their discovery seems as remote as ever we may after all be on its threshold. It is to be remembered that what is really wanted is not a new source of energy, but some means of controlling and so utilising forms of energy already well known. The energy of chemical combination has only so far been utilised for destructive purposes. Attempts to make a gunpowder engine preceded the completion of the steam engine, but no man has ever succeeded in utilising the force of explosives for any mechanical purpose except that of imparting velocity to bullets and cannon balls, or of rending and shattering matter by the sudden strains and pressures arising from heat generated by the instantaneous combination of certain chemical elements.

Sir Oliver Lodge, our latest Albert Medallist, has recently drawn attention to the possibilities of utilising the atomic energy the existence of which has been made known to physicists by the discovery of radium. Sir Oliver tells us of forces which seem to bear something like the same relation to the forces of chemical combination as these bear to the powers we get in a steam boiler, but neither he, nor anybody else, is able to suggest any device by which we might be able to control this illimitable strength to the service of man. Only a small portion of it is wanted. It must be remembered that the steam engine utilises less than a fifth of the energy residing in the fuel, the internal-com-

bustion engine not much more than a quarter.* There is abundant margin for waste, and coming generations may be quite satisfied if their earlier atomic-energy engines can utilise a tenth of the abundant store available.

However, I am glad to be able to congratulate the Fellows of the Society, in that they will shortly have the opportunity of hearing from Sir Oliver Lodge himself what he has to tell us on this important subject. We shall gladly listen to what I am certain will be a clear and philosophical description of the powers that are available for our use, though it may not yet be possible to foretell the precise manner in which they may eventually be employed.

Sir Charles Parsons, in the address which he recently delivered to the British Association at Bournemouth, referred to a long-cherished notion of his own for utilising the internal heat of the earth by sinking shafts deep enough to reach a level where the temperature was sufficiently high. Such a bore-hole might be twelve miles deep, might cost £5,000,000, and might take eighty-five years to construct. Sir Charles considered the engineering conditions feasible, but admitted that it was quite uncertain whether the pressure at such depths might not cause the rock to crush in and destroy the shaft. But he is evidently a little keen on trying the experiment, for he urged the value of the scientific knowledge to be gained as a justification for it. At present the only attempt to utilise this source of energy appears to be that carried out in certain volcanic regions in Italy, where turbines are actually being driven by high-pressure steam obtained from bore-holes. As Sir Charles Parsons said, "it seems indeed probable that in volcanic regions a very large amount of power may be in the future obtained, directly or indirectly, by boring into the earth, and the whole subject deserves serious consideration."

But while we are insisting on the necessity of a proper use of all the benefits we have derived from scientific progress, is it not just worth while to remember that there is another side to the question? We have perhaps devoted ourselves too ardently to an idolatry of science, and we have had a bitter lesson that every human institution however beneficent has also its evil side and is productive of harmful as well as good results. The apostles of every new religion have dangled before the eyes of their disciples promises of a millennium more or less immediate. Humanity has revolted, and every creed in turn has marked its progress by persecution and intolerance. Great as are the benefits which Christianity has conferred on mankind, its generous altruism, its benevolence to the weak and suffering, its cultivation of the noblest ideals, its pure and unselfish morality, it has in the course of its triumphant progress been the direct cause of infinite human misery and suffering.

So has the progress of science during the past five years succeeded in off-setting the benefits it has conferred on mankind during the past century, by becoming the instrument of more concentrated human agony than the world has ever known since history began. Five years ago we were continually exulting over the benefits conferred on humanity by the rapid progress of scientific knowledge. We cannot date the commencement of the practical application of science much further back than a single century. If we could put into one scale the benefits received in a hundred years, and into the other the misery produced by scientific inventions in five, which way would the balance of human happiness swing?

To take up this point of view is not to attack science or to decry religion—efforts to my mind of equal ineptitude and folly; it is merely to follow the advice of the wisest of men, the father of all modern philosophy, though he lived nearly 2,500 years ago, who beyond all things inculcated the value of moderation—temperantia—σωφροσύνη, and like all wise philosophers distrusted and condemned the folly of extreme views.

The precise share which the Society can most efficiently take in the great task of reconstructing British industrial organisation it is hardly possible—perhaps hardly desirable—to anticipate. It will willingly accept, and to the best of its ability discharge, any duties it can usefully undertake. It must be remembered that its influence is very widespread, and extends to every corner of the Empire. At least a third of its total membership consists of residents beyond the seas, and, indeed, includes a certain proportion of actual foreigners

* The most recent estimate of the amount of energy utilised in our best engines will be found in a paper read by Sir Dugald Clerk to the North-East Coast Institution of Engineers in July last. According to Sir Dugald Clerk's calculations the best steam engine in 1914 utilised 16·8 per cent. of the theoretical energy in the fuel, and the best gas-engine 28·4. The limiting efficiencies which appear to be the highest possible with present knowledge, that is to say theoretically possible with engines designed but not yet constructed, are given by Sir Dugald as for the steam turbine 28 per cent., and for the internal-combustion engine 46 per cent.

as well as residents in foreign countries. We have many American members, and shall be glad to have many more. This is one chief source of the Society's strength and of its growing influence.

Since its foundation in the middle of the eighteenth century, one of the principal objects which the Society has consistently and persistently held before it has been the application of scientific knowledge to the purposes of practical life. Long before such a thing as scientific research can be said to have existed, except indeed in a sporadic form, and as the pursuit of individual inquiries, it was searching for new industrial materials, encouraging new methods of employing them, and rewarding new devices for treating them. This was all done in an empirical and unsystematic fashion, but in the days when science itself was as yet unsystematised and undeveloped, it were idle to expect any regular system for its useful employment. It was not until the later years of the eighteenth century and the earlier of the nineteenth that chemistry and physics, created and established by the devotion of a succession of great philosophers, were first systematised and then devoted to human benefit by a series first of brilliant students and afterwards by a number of energetic inventors, manufacturers, and engineers.

All the while the Society was taking its share in the work of progress, though as time went on new and more specialised institutions arose to deal each with its own particular branch of the multifarious and complicated organism. During its long history its methods have changed from time to time, but it has always discharged the special duty of diffusing information about the practical results of scientific research. Professor Tyndall was once invidiously, but quite correctly, described as the most eminent *vulgarisateur* of science, for the reproach suggested by the English equivalent is, I believe, by no means involved in the French epithet. It is as essential that scientific discoveries should be published as that they should be made, and the provision of a regular organisation for disseminating knowledge of scientific progress is almost more needed than the provision of an organisation for promoting it. Science may develop by individual and silent effort, but it can render no help to human progress until the outcome of that effort is published abroad.

It is now, and has been for a great many years, regarded as the principal duty of the Society that it should provide its members, at their regular meetings, with the opportunity of hearing from the lips of the discoverers themselves, or of other competent persons, accounts of those applications of science to purposes of daily life of which our time is so productive. This duty it has effectively discharged, and the testimony is to be found in the columns of its *Journal*, comprising as they do an encyclopædic history of the progress of industrial science for a period of much more than half a century.

The Society has originated many new projects, and has promoted the progress of many novel ideas, and as opportunity serves it will continue in the future its useful labours of the past. The times, as I said before, are hard for institutions as for individuals. Our resources are limited, but our numbers are increasing, and so long as we have this proof of public approval there is no reason why we should not look forward to our future with serene confidence, as we are justified in looking back upon our past with legitimate pride.

After delivering the address the Chairman presented the Society's medals which were awarded for papers read during last Session:—

At the Ordinary Meetings:—

Edward C. de Segundo, Assoc.M.Inst.C.E., M.I.Mech.E., M.I.E.E., "The Removal of the Residual Fibres from Cotton Seed, and their Value for Non-textile Purposes."

Sir Frank Heath, K.C.B., Secretary, Department of Scientific and Industrial Research, "The Government and the Organisation of Scientific Research."

Walter Leonard Lorkin, A.M.I.E.E., "Electric Welding and its Applications."

W. Norman Boase, C.B.E., "Flax—Cultivation, Preparation, Spinning, Weaving."

In the Indian Section:—

Brigadier-General Lord Montagu of Beaulieu, C.S.I., "Aviation as affecting India."

In the Colonial Section:—

Professor John Cunningham McLennan, O.B.E., Ph.D., F.R.S., "Science and Industry in Canada."

Mr. Alan A. Campbell Swinton, F.R.S., said it was his pleasant duty to ask the meeting to accord a very hearty vote of thanks to their Chairman for the exceedingly interesting address he had delivered. The Society was to be congratulated in that Sir Henry Wood had brought his long connection with it to a culmination by becoming Chairman of the Council—the highest honour the Council could bestow. Sir

Henry was the embodiment of all that the Society stood for. The principal object of the Society was the dissemination of knowledge—a very important function indeed. The majority of scientific discoveries and inventions were put forward by their originators in language which it was difficult for the average man to understand, and the aim of the Society was to explain all such discoveries in a more popular manner. Manufacturers and others, whose business it was to apply these discoveries to industry, could not afford the time to follow all the details and ramifications of scientific research, and an Institution like the Society of Arts performed most useful work in placing the results of such researches before them in a manner which would enable them to apply them to their industries. The Chairman's address was a record of what had been done by the Society in that connection during the past century, and it was a record of which they might well be proud, and which they hoped to continue in the future under his auspices. He asked the meeting to accord their heartiest thanks to Sir Henry Wood for his admirable address.

The Hon. Richard Clere Parsons, in seconding the motion, said the exceedingly illuminating address which the Chairman had given them explained very clearly the part that the Germans had played in connection with industry in the past. It was now their duty to consider how they were going to profit as the outcome of the terrible war which had at last been brought to an end. He thought that the industries which had been so much weakened by German competition in the past would now recover, and it was their duty to see that that recovery was maintained, and that trade was not allowed to go back into enemy hands. Sir Henry Wood had covered the ground most completely in his address, and had shown the great part which their Society had played in assisting the industries of the country, and that was a part which they must continue to play in the future. He hoped that Sir Henry would enjoy the best of health during his term of office and for a long time to come.

The vote of thanks was then carried with acclamation.

The Chairman (Sir Henry Wood) said he was very much obliged to the meeting for their expression of thanks and for the patience with which they had followed his address.

The meeting then terminated.

MANGANESE MINES IN ECUADOR.

The manganese mines of Ecuador, which are becoming known in the United States as a number of shipments of the product have been sent there recently, are situated near the town of San Antonio, Province of Pichincha, and cover an area of about one and a third square miles.

According to a report by the United States Consul-General at Guayaquil, the principal deposit so far discovered consists of a blanket vein of manganese three to nine feet thick, and an extension of some 21,000 sq. ft., a portion being exposed. Samples from many other deposits in the vicinity, of undetermined extent, appear to be of equal quality, from which it is assumed that the available quantity of ore reaches many thousands of tons.

Work was begun at the principal deposit in February, 1918, with a limited force and in a primitive manner, about five tons being the daily output with ten men working. The ore extracted was dried in the open air and bagged for export, resembling gravel in appearance.

An assay made in New York gave the following percentages: Manganese, 46·36; iron, 1·55; copper, 0·02; phosphorus, 0·14; silica, 6·44. Other samples showed 53·2 per cent. of manganese; some have a higher percentage of silica, and still others show limestone. The small quantity of phosphorus should be noted.

The mines are 7,874 ft. above sea-level; the climate is healthy; and the rainy season lasts from January to April, with a small rainfall. The district is wholly volcanic, partly covered with sand, and the Guaillabamba River passes through a deep gorge near by.

No experienced miners are available, but the native workmen, of which the supply is sufficient, are easily managed and learn readily. Quito, the railway terminus, is twenty-eight miles from the mine; the road is fairly passable to mule traffic, and could be fitted for wagons by constructing a small bridge.

OBITUARY.

Admiral Charles John Rowley.—Admiral Charles John Rowley died at his residence, Holmesland, Botley, Hants, on the 11th inst., at the age of eighty-six.

He entered the Navy in 1844, and was made a lieutenant ten years later. He served in this rank on the "Curlew" and "St. Jean d'Acre," and was present at the operations before Sebastopol in 1854-5. He also took part in the Azoff Expedition and the capture of Kimburn Kertch Yemikali. For these services he received the Crimean Medal, with the Azoff and Sebastopol clasps, and Turkish decorations. He was promoted commander in 1861, and captain in 1866, commanding, among other vessels, the "Pallas" and the "Iron Duke." In 1884 he was advanced to flag rank, and in 1887-8 he was second in command of the Channel Squadron. He became Admiral in 1895, and retired in 1897.

Admiral Rowley had been a member of the Society since 1877.

Earl Brassey, D.C.L.—The death of Earl Brassey took place on the 12th inst. as the result of an accident in which he was run over by a taxi-cab.

Born in 1863, he was educated at Eton and Balliol College, Oxford, of which he was elected later in life an honorary Fellow. When the South African War broke out he went with the Sussex Yeomanry on active service. After the fall of Pretoria in 1900, he became first acting Civil Commissioner for the British Government there, and from that time onwards he took a deep interest in South Africa and in imperial interests generally. His views on these subjects he embodied in his book, "Problems of Empire."

Mr. Brassey made several attempts to enter the House of Commons, but without success. He was, however, Assistant Private Secretary to Lord Spencer at the Admiralty, and, like his father, he was intensely interested in the Navy. He edited the *Naval Annual* from 1890, and he contributed special chapters on the progress of the British Navy, and the relative strength of the navies of the world.

In addition to his political work he was a very good friend to his "Alma Mater," and was the founder of the Oxford University Endowment Fund. He also served on the Archbishop's Committee on Church Finance in 1910 and 1911, and was Chairman of the Central Board of Finance of the Church of England. During the war he succeeded in controlling mines in Sardinia hitherto owned by German firms; and in 1917 he performed good work in Rome in connection with the Mediterranean lines of communication from Cherbourg to Taranto. He was made a Commander of the Crown of Italy.

Lord Brassey succeeded his father as second earl in 1918. The first earl had been a member of the Royal Society of Arts since 1862, and served on the Council for some forty years. The second earl was only elected a Fellow last year.

GENERAL NOTES.

The Prickly Pear in Australia.—A bulletin issued by the Institute of Science and Industry (Commonwealth of Australia) deals with one of the greatest obstacles to pastoral and agricultural progress in a large portion of the Commonwealth. An area of over 20,000,000 acres is infested with prickly pear in Queensland, and an area of over 2,200,000 acres in New South Wales. The rate of increase of the pest is estimated at 1,000,000 acres per annum. No discrimination is shown in the land attacked. Rich country is as quickly overcome as poor country, and in a short time is rendered unproductive and valueless. The plant is extremely difficult to eradicate, and no satisfactory machine for destroying it has yet been invented. The manufacture from it of alcohol, paper or cardboard, potash, and various other materials has been suggested, but the fact that prickly pear contains a very large percentage of water makes its profitable commercial utilisation very unlikely.

East African Markets.—One effect of insufficient tonnage has been the entrance of South Africa into the markets of Equatorial Africa. Mr. T. Sleith, M.B.E., who has recently visited the territories in question as special Trade Commissioner to the Union Government, was instructed to investigate the position, not only as to exports from South Africa, but as to the supply of various raw materials required in the Union for primary industries. In a valuable report which has been presented to the Union Houses of Parliament, Mr. Sleith says he does not anticipate any large volume of trade for some time to come, but considers that as South African manufacturers are now in the East African markets, every effort should be made to retain that share of business which has fallen to them. Central Africa, as a source of certain raw materials and products, he continues, is of primary and paramount importance to the Union, and as its industries extend and develop this will become more apparent. "In these territories is an unlimited supply of copra, palm-oil, ground-nuts, sim-sim, sisal, beeswax, hides and skins, and other commodities equally important to industrial manufacture, and it is to Central Africa that the Union must look, owing to the geographical advantage, which will be much more pronounced when shipping and freights resume a more normal condition." Many merchants complained to Mr. Sleith of the way in which certain articles of Union manufacture—chocolates, biscuits, tobaccos, and cigarettes—turned out. "It is quite obvious," he declares, "that the biscuits and chocolates do not keep as long as the English article." He also urges the need for improvement in packing methods.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday afternoons, at 4.30 p.m.:—

November 26.—H. B. Morse, LL.D., late Statistical Secretary, Inspectorate-General of Chinese Customs, "British Trade in China." Byron Brenan, C.M.G., late H.B.M. Consul-General, Shanghai, will preside.

December 3.—John Westall Pearson, Chairman and Director, British Oil and Cake Mills, "The Oil Seed Crushing Industry." The Right Hon. Lord Lamington, G.C.M.G., G.C.I.E., will preside.

December 10.—Sir Oliver Lodge, D.Sc., Sc.D., LL.D., F.R.S., "Some Possible Sources of Energy." (Trueman Wood Lecture.)

December 17.—Constantine Grunewald, late Chief of Intelligence Department, Russian Ministry of Trade and Industry, "The Present Economic Position of Russia, and some Aspects of its Future Development."

COLONIAL SECTION.

Tuesday afternoon, at 4.30 p.m.:—

DECEMBER 9.—SIR EDWARD DAVSON, President of the Associated West Indian Chambers of Commerce, "Problems of the West Indies." LIEUT.-COLONEL L. S. AMERY, M.P., Under-Secretary of State for the Colonies, will preside.

INDIAN SECTION.

Thursday afternoon, at 4.30 p.m.

DECEMBER 18.—P. J. HARTOG, C.I.E., M.A., Member of the Calcutta University Commission, 1917-1919, "Some Problems of Indian Education."

Papers to be read after Christmas:—

BRIGADIER-GENERAL EDWARD MAITLAND, D.S.O., "The Commercial Future of Airships."

SIDNEY PRESTON, C.I.E., "English Canals and Inland Waterways."

BRIGADIER-GENERAL SIR HENRY P. MAYBURY, K.C.M.G., C.B., M.Inst.C.E., "Road Transport."

CHARLES H. SHERRILL, "Stained Glass."

ALFRED E. HAYES, General Secretary, English Language Union, "The English Language and International Trade."

JAMES CURRIE, C.M.G., Ministry of Labour (Training Department), late Principal, Gordon Memorial College, Khartoum, "Industrial Training."

LADY INGLEFIELD, President, Buckinghamshire Lace Association (North Bucks and Bedfordshire), "The Hand-made Lace Industry."

GRAILY HEWITT, "Rolls of Honour."

ALFRED H. POWELL, "Ancient Cottages and Modern Requirements." The Right Hon. EARL FERRERS will preside.

CHARLES CROWTHER, "The Arts and Crafts of Japan" (with examples from the author's private collection).

SIR CECIL HERTSLET, late H.M.B. Consul-General for Belgium, "The Ruin and Restoration of Belgium." EMILE CAMMAERTS will preside.

WILLIAM CRAMP, D.Sc., M.I.E.E., "Pneumatic Convoying Plants, with special reference to the Transport of Grain."

L. GASTER, "Industrial Lighting in its relation to Efficiency."

H. M. THORNTON, "Gas in relation to Industry and Housing."

LIEUT.-COMMANDER NORMAN WILKINSON, R.N.V.R., O.B.E., R.O.I., R.I., "Naval Camouflage."

BRIGADIER-GENERAL LORD MONTAGU OF BEAULIEU, C.S.I., "Motor Transport in India."

SIR GEORGE CUNNINGHAM BUCHANAN, K.C.I.E., M.Inst.C.E., "The Ports of India: their Administration and Development."

SIR JOHN HUBERT MARSHALL, C.I.E., M.A., Litt.D., F.S.A., Director-General of Archæology in India, "Recent Archæological Discoveries in India."

SIR VALENTINE CHIROL. (Sir George Birdwood Memorial Lecture.)

SIR FRANCIS WATTS, K.C.M.G., D.Sc., Imperial Commissioner of Agriculture for the West Indies, "Tropical Departments of Agriculture, with special reference to the West Indies." LIEUT.-COLONEL SIR DAVID PRAIN, C.M.G., C.I.E., LL.D., F.R.S., Director of the Royal Botanic Gardens, Kew, will preside.

INDIAN SECTION.

Thursday afternoons, at 4.30 p.m.:—

January 15, February 19, March 18, April 15, May 20.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 p.m.:—

February 3, March 2, May 4.

CANTOR LECTURES.

Monday evenings, at 8 p.m.:—

JOHN THEODORE HEWITT, M.A., D.Sc., Ph.D., F.R.S., Emeritus Professor of Chemistry, East London College, "Synthetic Drugs." Three Lectures.

Syllabus.

LECTURE I.—DECEMBER 1.—Introductory—Simple aliphatic compounds—Alcohols, formaldehyde, paraldehyde—Ketones and derivatives such as sulphonal—Veronal and other compounds derived from urea—Non-aromatic cyclic compounds, *e.g.* the derivatives of Borneol.

LECTURE II.—DECEMBER 8.—Phenol, salicylic acid and related substances—Derivatives of aromatic amines and aminophenols, *e.g.* phenacetin—Compounds of heterocyclic structure, antipyrine, flavine, etc.

LECTURE III.—DECEMBER 15.—Modified alkaloids, *e.g.* heroin, euquinine—Organic compounds of arsenic (atoxyl, salvarsan), antimony mercury and other metals—Conclusion.

CAPTAIN H. HAMSHAW THOMAS, M.B.E., M.A., F.G.S., Fellow of Downing College, Cambridge, and formerly of the Royal Air Force, "Aircraft Photography in War and Peace." Three Lectures.

January 19, 26, February 2.

CHARLES FREDERICK CROSS, B.Sc., F.R.S., F.C.S., "Recent Research in Cellulose Industry." Three Lectures.

February 16, 23, March 1.

WALTER ROSENHAIN, B.A., D.Sc., F.R.S., Superintendent, Department of Metallurgy and Metallurgical Chemistry, National Physical Laboratory, "Aluminium and its Alloys." Three Lectures.

April 12, 19, 26.

ARTHUR THOMAS BOLTON, F.R.I.B.A., F.S.A., Curator, Soane Museum, "The Decoration and Architecture of Robert Adam and Sir John Soane, 1758-1837." Three Lectures.

May 3, 10, 17.

JUVENILE LECTURES.

Wednesday afternoons, at 3 p.m.:—

LOUGHNAN PENDRED, M.I.Mech.E., Editor of *The Engineer*, "Railways and Engines."

January 7, 14.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, NOVEMBER 24...Ingénieurs Civils, Société des (British Section), at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5.30 p.m.

Swiney Lectures, Imperial College of Science, South Kensington, S.W., 5.30 p.m. Dr. J. D. Falconer, "The Geology and Mineral Resources of the British Possessions in Africa." (Lecture VII.)

Electrical Engineers, Institution of (North-East Centre), Armstrong College, Newcastle, 7.15 p.m. Mr. W. D. Owen, "Wireless Telegraphy in the Mercantile Marine."

Actuaries, Institute of, Staple Inn Hall, Holborn, W.C., 5 p.m. Dr. C. E. Howell, "The Reversionary (or Prospective) and Collective Methods of Valuing Widows' Funds, with some Notes on the Valuation of Church of Ireland Widows' and Orphans' Fund."

TUESDAY, NOVEMBER 25...Illuminating Engineering Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5.30 p.m. 1. Presidential Address on "The Work of Lambert." 2. Exhibition of High Candle-power Lamps and New Developments in Photometry.

Royal Dublin Society, Leinster House, Dublin, 4.15 p.m. 1. Mr. T. G. Mason, "On some Factors affecting Concentration of Electrolytes in the Leaf-sap of *Syringa vulgaris*." 2. Mr. L. B. Smyth, "The Carboniferous Coast Section at Malahide." 3. Mr. J. J. Dowling, "An Apparatus for the Production of High Electrostatic Potentials."

University of London, University College, Gower-street, W.C., 5.30 p.m. Mr. J. H. Helweg, "Holberg and Ewald." (Lecture IV.)

Electrical Engineers, Institution of (North-Midland Centre), Victoria Hotel, Sheffield, 7 p.m. Discussion on "The Use of Electrical Machinery in Goods Stations and Yards."

Civil Engineers, Institution of, Great George-street, S.W., 5.30 p.m. Mr. H. H. Gordon, "Metropolitan Road and Rail Traffic."

Photographic Society, 35, Russell-square, W.C., 7 p.m. Mr. C. P. Crowther, "'No' and other things Japanese."

Anthropological Institute, 50, Great Russell-street, W.C., 8.15 p.m. Dr. W. Strong, "Some Personal Experiences in British New Guinea."

Colonial Institute, Central Hall, Westminster, S.W., 3.30 p.m. Lieut. E. W. P. Chinnery, "Unknown New Guinea."

WEDNESDAY, NOVEMBER 26...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Dr. H. B. Morse, "British Trade in China."

Aeronautical Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. G. Brewer "Some Kite Balloon Experiments."

British Academy, Burlington House, W., 5 p.m. Mr. John Bailey, "Poetry and Commonplace."

Swiney Lectures, Imperial College of Science, South Kensington, S.W., 5.30 p.m. Dr. J. D. Falconer, "The Geology and Mineral Resources of the British Possessions in Africa." (Lecture VIII.)

Oriental Studies, School of, Finsbury-circus, E.C., 5 p.m. Mr. L. Binyon, "The Art of Asia. Lecture II.—India."

United Service Institution, Whitehall, S.W., 3 p.m. Major-General Sir G. Aston, "Combined Operations."

Public Health, Royal Institute of, 37, Russell-square, W.C., 4 p.m. Dr. N. Raw, "Housing in Relation to Tuberculosis and other Infectious Diseases."

University of London, University College, Gower-street, W.C., 3 p.m. Mr. E. G. Gardner, "History and Drama in the Divina Commedia." (Lecture VI.) 5.30 p.m. Mr. H. E. Palmer, "Methods of Learning Foreign Languages." (Lecture IV.) Mr. I. C. Gröndahl, "Holberg and Wessel." (Lecture IV.) 6.15 p.m. Mr. J. C. Stamp, "Fundamental Principles of Taxation in the Light of Modern Developments." (Lecture IV.)

THURSDAY, NOVEMBER 27 ... Cold Storage and Ice Associations, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5 p.m.

Royal Society, Burlington House, W., 4.30 p.m.

University of London, University College, Gower-street, W.C., 5.30 p.m. Professor A. Cippico, "La Poesia di Giovanni-Pascoli." (Lecture V., in Italian.) Mr. I. Bjorkhagen, "Selma Lagerlof." (Lecture IV.)

Auctioneers and Estate Agents Institute, 34, Russell-square, W.C., 7.45 p.m. Sir W. Wells, "The Future of Professional Education."

Electrical Engineers, Institution of, at the Institution of Civil Engineers, Great George-street, S.W., 6 p.m. Messrs. C. C. Paterson, J. W. T. Walsh, A. K. Taylor, and W. Barnett, "Carbon Arcs for Searchlights."

China Society, at the School of Oriental Studies, Finsbury-circus, E.C., 5 p.m. Professor M. Smith, "Industrial Changes in China."

Mechanical Engineers, Institution of, at the Engineers' Club, Albert-square, Manchester, 7 p.m. Mr. C. G. Conradi, "The Present Position of Mechanical Road Traction."

FRIDAY, NOVEMBER 28...Swiney Lectures, Imperial College of Science, South Kensington, S.W., 5.30 p.m. Dr. J. D. Falconer, "The Geology and Mineral Resources of the British Possessions in Africa." (Lecture VI.)

Engineers and Shipbuilders, North-East Coast Institution of, Westgate-road, Newcastle-on-Tyne, 6.15 p.m. Mr. A. Hogg, "Test of Watertight Bulkheads for Ship Subdivision."

University of London, University College, Gower-street, W.C., 8 p.m. Professor G. D. Hicks, "An Introduction to Modern Philosophical Thinking." (Lecture IV.)

Mechanical Engineers, Institution of, The University, Sheffield, 8 p.m. Mr. C. G. Conradi, "The Present Position of Mechanical Road Traction."

Physical Society, Imperial College of Science, South Kensington, S.W., 5 p.m. Discussion on Lubrication.

SATURDAY, NOVEMBER 29...National Special Schools Union, at the ROYAL SOCIETY OF ARTS, John-street Adelphi, W.C., 10 a.m.

Journal of the Royal Society of Arts.

No. 3,497. VOL. LXVIII.

FRIDAY, NOVEMBER 28, 1919.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

MONDAY, DECEMBER 1st, at 8 p.m. (Cantor Lecture.) JOHN THEODORE HEWITT, M.A., D.Sc., Ph.D., F.R.S., Emeritus Professor of Chemistry, East London College, "Synthetic Drugs." (Lecture I.)

WEDNESDAY, DECEMBER 3rd, at 4.30 p.m. (Ordinary Meeting.) JOHN WESTALL PEARSON, Chairman and Director, British Oil and Cake Mills, "The Oil Seed Crushing Industry." The Right Hon. LORD LAMINGTON, G.C.M.G., G.C.I.E., will preside.

Further particulars of the Society's meetings will be found at the end of this number.

JUVENILE LECTURES.

The usual short course of lectures adapted to a juvenile audience will be delivered on Wednesday afternoons, January 7th and 14th, 1920, at 3 p.m., by Mr. LOUGHNAN PENDRED, M.I.Mech.E., Editor of *The Engineer*, on "Railways and Engines."

Special tickets are required for these lectures. They can be obtained on application to the Secretary.

A sufficient number of tickets to fill the room will be issued to Fellows in the order in which applications are received, and the issue will then be discontinued. Subject to these conditions, each Fellow is entitled to a ticket admitting two children and one adult. Fellows who desire tickets are requested to apply for them at once.

PROCEEDINGS OF THE SOCIETY.

SECOND ORDINARY MEETING.

Wednesday, November 26th, 1919; BYRON BRENAN, C.M.G., late H.B.M. Consul-General, Shanghai, in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Brocklebank, Captain H. Cyril R., R.N., O.B.E., Tarporley, Cheshire.
Croft, Albert John, Birmingham.
Dunning, Harold Frederick, London.
Grant, Gustavus John, Birmingham.
Mercer, Raymond G., Manchester.
Paxman, Edward Philip, Bournemouth.
Plant, A. Edmund, Poulton-le-fylde, Lancs.
Reed, T. A. Woolterton, London.
Saunders, Arthur D., Bexhill-on-Sea.
Skelley, Horatio Arthur, Hyde, Cheshire.

The paper read was—

BRITISH TRADE IN CHINA.

By H. B. MORSE, LL.D.,
Late Statistical Secretary, Inspectorate-General of Chinese Customs.

My subject is narrower than my title. I propose to-day to treat only of English trade—the trade of the United Kingdom; and I shall refer to British trade—the trade of the British Empire—only in so far as it affects English trade. In fact, during the first phase of the trade, from 1637 to 1833, a broad distinction must be made between two branches: the monopoly trade of the English East India Company between London and Canton, and the "country" trade between Canton and ports east of the Cape of Good Hope, open under licence to all British subjects, whether they belonged to London or Glasgow, to Calcutta or Bombay.

I must also take note of another limitation on my title: I shall not prescribe dogmatically for the future. I stand here as the theorist, the economist, the statistician, addressing a gathering of practical men—administrators, industrialists, merchants—and my words will be of use to you only in so far as I stand on a foundation of historical fact. When I try to look into the future I am confronted by the warning of the wise man, who bade us "never prophesy unless you know." What I can do

for you, however, is to give you an account of the past and the present; and if I can construct a curve connecting that past with the present, it will be for you, with your practical knowledge, to project the curve into the future, making due allowance for disturbing factors which might deflect the curve upward or downward.

England was relatively late in entering the China field—even in those days she needed a leader to urge her to "Wake up, England!" She had been preceded first by Portugal, whose people were the bold explorers, navigators, and oceanic traders of the fifteenth and sixteenth centuries. They established themselves in India and in the Spice Islands, making Lisbon for a time the prosperous rival of Venice and Genoa as a mart for distributing the silks, spices, and other luxuries of the Far East. In 1511 they took Malacca, the entrepot on the gateway to the Farther East, and in 1517 their first ships arrived at Canton. The Spanish arrived in 1575, coming from the West, from America and the Philippines; but they took no active part in the trade, and for a century the Portuguese had it to themselves, acting as the sole intermediaries in bringing Chinese produce by sea to the European markets. Success and prosperity encouraged the buccaneering instinct which characterised all European nations in the sixteenth century, and the Chinese Government found it expedient to suppress the factories along the coast, as far north as Ningpo at the mouth of the Yangtze, burning the ships, killing hundreds of Portuguese, and slaughtering thousands of their Chinese adherents. In 1557 they were allowed to settle on the barren peninsula of Macao, and there for three centuries, under Chinese jurisdiction—territorial, judicial, and fiscal—they provided the threshold by which European traders obtained access to the Chinese market.

The men of the free Netherlands came next—the men of Rotterdam and Amsterdam, but not those of Antwerp and Ostend; men who made a world-wide trade, even with their enemy, support their hundred years' war with Spain. The refrain of the old song tells us that—

> "Nutmegs and ginger, cinnamon and cloves,
> Oh, they gave me this jolly red nose;"

but, together with pepper and sugar, they also provided a flavouring for the otherwise flavourless diet of Mediaeval and Renaissance Europe, and they came to Europe from the East. The routes developed by Venice and Genoa had been blocked by the Turkish occupation of Trebizond, Constantinople, Alexandria, and the Levant generally, and Lisbon had become the primary port of entry of Asiatic spices into Europe. The annexation of Portugal by Spain in 1580 made it uncomfortable for the Dutch to frequent the market-place of Lisbon; and, after thinking it over in the leisurely way characteristic of the time, they sent out a strong fleet to Eastern waters. In the years 1604 to 1610, with this fleet, by the occupation of Amboyna, Java, and other islands, formerly Portuguese, they laid the foundation of the Dutch colonial empire, and solved radically the problem of obtaining spices for their table and their trade. In 1604 they attempted to trade at Canton, but the attempt was frustrated by Portuguese jealousy; in 1622 a fleet of fifteen ships attacked Macao, but was beaten off with heavy loss; in 1624 they occupied Formosa, then a no-man's land, but were driven out in 1662. Thereafter they traded at Amoy, and obtained access to Canton only in 1685, when the enlightened Emperor Kanghi threw open the trade to all nations.

It was more than a hundred years after the arrival of the Portuguese that, in 1637, the first English ships came to Canton, and nearly another hundred years elapsed before England began to rub her eyes and wake up—one ship in 1664, one in 1674, these two to Canton; one in 1670, one in 1677, these to Amoy; four ships in forty years, but thereafter about one a year, mostly to Amoy. About 1700 the English East India Company began to send sporadic ships, more or less every year, to Canton; and in 1715 it established a permanent factory at Canton, carrying on from year to year, and no longer treating each ship as a separate transaction.

The French sent their first ship to Canton in 1660, and established their factory there in 1728. They were followed by others of the European States, and before the end of the eighteenth century every flag of Western Europe was represented. A very few ships, such as those of Hamburg, Bremen, Lübeck, and an occasional ship from an Italian state, came without governmental encouragement, support or control; and the Portuguese, content with their position at Macao, seem not to have subjected their trade at Canton to official control; but, generally speaking, the ships and trade of each nation were under the absolute monopolistic control of the East India Company of that nation—English, Dutch, French, Prussian, Imperial (Ostend), Danish, Swedish. England was at last awake in a somnolent eighteenth-centuryish way, and her trade

became very soon the dominant element in the Canton factories.

More latitude, more relaxation from the strict monopoly, was granted to British merchants than to those of other nationalities. The East India Company continued to arrogate to itself the sole right to trade, both inwards and outwards, between Canton and England—in fact, between Canton and all ports west of the Cape of Good Hope; but it granted to British merchants, not only the English but also the Parsees, Jews, Bengalis and others of Calcutta, Bombay, Madras and other ports, licences to engage in the "country" trade between Canton and ports east of the Cape of Good Hope. Apart from this relaxation, close monopoly was the rule on both sides, for foreigners and for Chinese.

Into this world of monopoly came the intrusive free-trading Americans in 1784, the first year in which an American ship under the American flag could cross the ocean in comparative safety. Their merchants were as intelligent and as keen, their sailors as hardy and as enterprising, as those of the stock from which they sprang. In 1788 the ship "Alliance" sailed with no charts of eastern waters on board except the maps on Mercator's projection in a school-atlas, and did not drop anchor during the whole of her voyage from Philadelphia to Canton; and American merchants and supercargoes supplied just that spur of competition and co-operation on an equal footing which is all that the English needed—in those days—to bring out all that was best in them.

There were no statistics of trade in those days; all transactions were veiled in mystery. Of this I will give one illustration. The only mail carriers were the trading ships, and these carried cargo, inwards and outwards, each for only one merchant. When, after a voyage of five months, letters arrived to any other address than that of the consignee of the ship, they were interned during the stay of the ship, perhaps three months, for fear lest they should contain commercial intelligence of value to competing firms; and were delivered to the addressees *after* the departure of the ship which brought them. I have, however, collected a few scattered notes, which have a certain value since, in the eighteenth century, British ships invariably brought goods consigned to a British merchant, and carried away produce shipped by a British merchant; and so with all other flags.

In 1751, Osbeck, a Swedish scholar, notes that, on arriving at Whampoa (the anchorage for Canton) he found there 9 English ships, 4 Dutch, 1 Danish, and 2 Swedish, a total of 18; as the British included those of the East India Company, huge leviathans of 800 to 1,200 tons burthen, while other ships would be between 300 and 500 tons, the English tonnage was three-fifths of the total. His ship, of the Swedish East India Company, was 9 months and 11 days on the voyage out (2 months and 16 days spent at Cadiz), stayed 4 months and 10 days at Whampoa; and arrived at Gothenburg after a voyage of 5 months and 22 days, with thanks to God for the safe return of the 124 men on board. Except for a few tons of lead, she provided for her outward cargo by carrying silver dollars. Her outward lading from Canton was as follows: 1,232,187 lb. of tea; 5,047 lb. of raw silk; 4,055 pieces of silk stuffs; 5,319 pieces of cotton stuffs (Nankeens); 4,171 lb. of rhubarb; 1,263 packages of porcelain; 2,250 lb. of mother-of-pearl; 6,325 lb. of rattans; 35,314 lb. of galangal root; and 6,359 lb. of China-root.

Forty years later, in 1789, there was a total of 86 ships—61 British (21 Company, 40 country ships), 15 American, 5 Dutch, 1 French, 1 Danish, and 3 Portuguese. The British, in the same proportion of tonnage, had now 75 per cent., and the Americans, in the sixth year of their trade, 14 per cent. From this time the French Revolution and the subsequent wars drove the other flags away for twenty-five years, and left the trade entirely to the English and (except in the years 1813–1815) to the Americans, who shared it roughly in the proportion of three to one. This predominance the two nations never lost in the Canton factory days, even after the re-establishment of peace allowed the other nations to return. In the sixteen years, 1818 to 1833, the Dutch trade averaged 7 vessels in each year, of a total of 1,520 lasts (about 2,660 modern tons register), carrying imports averaging 498,950 dollars, and exports of an annual value of 468,330 dollars. No other Continental country exceeded about 100,000 dollars for imports and the same for exports. In those same years the American trade averaged 37 ships of 13,209 tons burthen (about 14,640 tons register); imports averaged 2,469,599 dollars in goods and 3,630,586 dollars in specie; exports averaged 6,453,492 dollars in goods, besides about 260,600 dollars a year disbursed for the shipping. The British trade was 56 a year (about two-fifths Company ships) of a total tonnage which I estimate between 60,000 and 70,000 tons. The imports averaged 18,765,319 dollars in goods, with only occasional lots of

specie (English products about 3 million dollars, Indian opium 6½ million, Indian cotton 4 million, other Asiatic produce 5 million). Exports averaged 13,100,000 dollars in goods and 3,500,000 dollars in specie (tea 7¾ million, silk and other products 5¼ million), besides about 450,000 dollars disbursed for the shipping. Of the export trade of those years we may say that 63 per cent. was British, 32 per cent. American, 2½ per cent. Dutch, and 2½ per cent. was divided between the other flags.

Thus, then, in 1833 the British flag had over three-fifths of the trade of Canton (which was China), the American a third, and the other flags "also ran"; and in those days the flag-trade meant national trade, and every ship carried goods, in or out, only for the merchant of her own nationality to whom she was consigned. Your attention will, however, be attracted to the small proportion of English manufactures (about 15 per cent.) entering into the British trade, and this small proportion was contributed by Leeds and Bradford, and not by Manchester; in those days cotton woven fabrics were shipped from Canton to London, and not from England to Canton.

The British trade was, broadly speaking, conducted on a triangular basis. The East India Company shipped English goods to Bombay and Calcutta, and, to the extent of that 15 per cent., to Canton; on this last item the Directors informed a committee of the House of Lords in 1820 that their net loss on English products in twenty-three years had been £1,688,103. Then country merchants (English and Indian) under licence shipped cotton and opium from India, and spices and other tropical products from the Southern Isles to Canton. Then, on the third leg of the triangle, Canton sent tea and silk, together with drug products and Chinese curiosities, to England, and, after about 1815, specie to India.

The American trade was, also broadly speaking, conducted on a triangular basis. Some ships carried American produce (flour, salted fish, etc) to Europe; then they engaged in the coasting trade as neutrals in a world of war; and then they sailed with a "cargo" of Spanish dollars for Canton, picking up on the way, perhaps, such goods as seemed to their supercargo to have a speculative value. Other ships loaded axes and beads, and in the South Pacific cut a cargo of sandalwood, which they carried to Canton. Others again carried supplies to the Spanish colonies on the Pacific coast, then bought furs at the Columbia and in Oregon, which they carried to Canton. Thence they all took tea, silk and other Chinese products back to their home port.

The problem of the merchant of that day was the dollar—the price at which it could be laid down; for the Chinese would take no other specie than the silver dollar, and that must be a Spanish dollar, and in the first half of the nineteenth century it must bo of the mintage of Charles IV. (1788-1808). At the outset Europe had few goods to send—few that the Chinese wanted, and every ship had to take what silver was required to buy a cargo of tea and silk. In 1683 the Directors of the English East India Company wrote referring to "the loss of Bantam to the Dutch, and the "Johanna" outward bound to your place (Amoy) with her stock of £70,000, most bullion." The necessity increased through the eighteenth century; and in the century and a third to 1833 I estimate that, on net balance, not less than five hundred million dollars in silver coin were imported into Canton and stayed there. The Napoleonic wars created a great demand for the same coin, and we know that Wellington was often at his wit's end to obtain dollars in competition with the demand for China, while, in their turn, the China traders had to buy dollars at much above their intrinsic value. In normal times there is no way of laying down the dollar so expensive as that of sending the actual coin over 15,000 miles of ocean, with five to seven months' demurrage for the ship; and the merchants were driven to discover some fertilising stream of goods to provide the funds for buying outward cargoes, for maintaining their establishments at Canton, for the disbursements on the ships, and to meet the Chinese exactions on their goods and their ships. Europe and America could send little the Chinese would buy, and yet the traders could not maintain their infertile stream of dollars.

The English traders were the first to extricate themselves. While the Chinese would not take a larger quantity of English products, it was found that they would take two Indian products — cotton and opium. Cotton, in quality superior to the Indian, is produced in the whole of the Yangtze basin of China (export in 1918 to Japan, 1,292,094 piculs = 431,000 bales); but, so exacting was the demand for goods to import, a large trade grew up in Indian cotton, its value in the years 1818 to 1833 being always greater than that of all English products, and in many of the years

being twice as great; its value exceeded that of opium until 1822, after which opium passed it. Opium was a prohibited article, which the Chinese bought freely; but, being prohibited, sales were always for cash, and opium was found to be so convenient a form of remittance that its imports increased rapidly, under 2 million dollars in 1818, to 4 million in 1823, to 10 million in 1829, and 12 million in 1833, in which year Indian cotton was 5½ million and English manufactures 2½ million. The English trade was now on a sound basis economically (I am not dealing with the moral aspect), and English ships ceased to bring specie from about 1815 except occasionally (3 million dollars in 1820, 1 million in 1824). From 1818 the English trade began to export specie between 2 and 4 millions a year to 1827, after that between 4 and 6 million a year, sent from Canton to Calcutta.

The American traders were longer in finding relief. Their own country supplied almost nothing that the Chinese wanted; they picked up what they could on the way; they carried Turkey opium from Smyrna, sometimes bought in London—a trade prohibited to the English traders; they arranged with English firms to receive Indian opium on consignment; but from first to last the specie imported in American ships constituted a much larger proportion of the lading than that of British ships. From 1818 to 1826 the specie was never less than twice, and was often more than thrice, the value of the goods on board. In those nine years American ships imported 49 million dollars, and British ships exported 19 million. In 1827 the Americans began to take bills on London as a means of remittance to Canton; these bills were bought there by the British merchants (English and Indian), and by them sent to Calcutta and Bombay. In the seven years 1827 to 1833 American ships imported no more than 8¼ million dollars, while British ships exported to India 36¼ million. The American trade sold London bills in Canton to the extent of 2½ million dollars in 1832 and 4¾ million in 1833.

I have said that, except for the Americans, the trade was under the strict control of a monopoly on both sides. Of the Chinese monopoly I shall say little; it would take too much of my space and of your time. One phase of it I may mention, however. Every foreign trader had to select a member of the Chinese Gild as his "security" merchant. He rented office and living accommodation to the foreigner, engaged his cashiers and servants, and "secured" them; to him alone the foreigner could sell his imports (opium excepted); from him alone could tea and silk and other exports be bought; and he was held responsible for every act connected with the foreign trader and his ships, from the purchase of a basket of fruit to homicide. *Per contra* the foreigner paid no customs duties; the security merchant paid them all, the regular and the irregular, the legal and the extortionate. Only on his ship did the foreign trader pay directly the exactions, amounting to 10 dollars, about £2, a ton and even more. Close restriction was the rule, and yet no one was dissatisfied. The Chinese officials were satisfied, as they made vast fortunes from the trade, more even from the prohibited opium than from the legal trade. (The Hoppo in one year accounted for a reported collection of 899,000 taels = 1,200,000 dollars. In that year I estimate that his gross collection from the trade, foreign and native, under his jurisdiction was not less than 13,000,000 dollars.) The Chinese merchants were unmercifully squeezed, but, *per contra*, they were backed by the full power of the government to milk the trade to its fullest capacity; and those who did not go bankrupt made huge fortunes. (Howqua in 1834 estimated the value of his own estate at 26,000,000 dollars.) The foreign traders made such profits as their Chinese friends allowed them to make; but their distant exile and their expert knowledge could not go unrewarded, and they were usually able to bring home a plum or two. On the whole, however, the situation is best summed up in Burke's comparison in 1783 of the Chinese monopoly with that of the English East India Company—"As the Chinese monopoly is at home, and supported by the country magistrates, it is plain it is the Chinese company, not the English, which must prescribe the terms." It was the Chinese Gild which prescribed the terms, and those terms were accepted by the foreign traders; they grumbled, of course—even the Americans were infected and grumbled; but the only serious note of protest was that of the English merchants against the monopoly of their own English company. They contrasted the restraints imposed on them with the freedom enjoyed by their only rivals, the Americans; and, supported by the Chambers of Commerce in England, they clamoured for the abolition of the monopoly of trade between England and China enjoyed by the East India Company. The monopoly was abolished and the trade thrown open from April 22nd, 1834.

The English in Canton were now a headless community, subject only to the nominal control of His Majesty's Chief Superintendent of Trade, and they found that, on the Chinese side, they had gained nothing, when, naturally and nationally individualistic, they were brought face to face with the close combination of the Chinese Gild, which was still "supported by the country magistrates." Five uncomfortable years followed, and then began the Opium War. The Chinese called it that, and that is what they will always call it; to them opium was the sole cause of the war. But in the settlement imposed on China, by force of arms, opium was not mentioned; Lord Palmerston's instructions were that it was open to the Chinese to prohibit the trade if they would, and suppress it if they could. The actual British claims were not admitted by China as negotiable, they were preposterous; but in the treaty they were the points that were settled—the equal national status of the United Kingdom and China, the right to appoint official consuls and not mere trading headmen, privilege of trading at five ports, abolition of (Chinese) monopoly, publication of a fixed customs tariff, jurisdiction over British subjects under criminal charges.

This was the first phase of the China trade, ending nominally in 1834, actually in 1842. It was a period of slow communications, when foresight and intelligent thought were required of the merchant, and when supplies were ordered for a future market and not to meet an existing demand. The ship which brought the goods brought also the merchants' advices; and in 1839, at a critical time when speed was imperative, important despatches from Captain Elliot took from five to seven months from Canton to London. Just as the phase was passing steam communication was introduced by the "overland route" across the Isthmus of Suez, and mails came at what seemed to the traders lightning speed. In 1841 Sir Henry Pottinger left London on June 5th, and after spending ten days at Bombay, arrived at Macao on August 10th—making sixty-six days; but he was a plenipotentiary hastening to his post. In 1844 the average time taken by the thirteen monthly mails from London to Hong Kong was eighty-four days; in 1859 this had been reduced to fifty days.

My second phase I take as ending in 1867, a date fixed with reference to the following events: end of the state of conflict between China and the West in 1860; suppression of the Taiping rebellion in 1864; world-wide monetary crisis in 1866; opening of the Suez Canal in 1869. It was the period of the fast-sailing tea clipper, when the merchant's goods went by sailing ship and his advices by steamer; but the telegraph cable reached Shanghai only in 1871. Foresight was still required and reaped its proper reward; but the merchant could now partially correct his errors of judgment, through having speedier mail communication. On the other hand, it still, prior to the opening of the Suez Canal, took from four to seven months for his goods, imports and exports, to reach their market. The period was one of great disturbances, and of great commercial opportunities—for profit and for loss. Friction between the Chinese government and the Western traders was continuous: but for the Chinese people, while those around Canton were exceedingly hostile—humiliated by defeat and embittered by the loss of their trading monopoly—those at Shanghai were most friendly. Rebellion spread over the whole empire, disturbing trade and disorganising the administration; as a consequence the officials, already corrupt by our Western standards, became more forth-putting in their corruption; and as a consequence of this the smuggling of opium was widespread, and assumed great proportions. This provided larger funds for a very much larger export trade —for the Chinese did not yet demand great quantities of European products. At the opening of the second phase Manchester was just beginning to send cotton fabrics to China, and England was just ceasing to take Chinese nankeens; through the phase Leeds continued to send woollens, but the demand did not greatly increase; and ships continued to take flints to light the Chinese fires and pipes.

During this phase, with friction constant between Chinese and British officials, the British Navy was doing the work of the Chinese government in suppressing piracy along the coast—was doing it even while England and China were at war; the British authorities at Hong Kong were giving the protection of the British flag to Chinese-owned shipping with the consent, and with the gratitude, of the Chinese authorities; the British, American, and French consulates were giving similar protection at Shanghai; and the situation was so anomalous that, on the same days, August 18th to 20th, 1860, the allied British and French troops were assaulting the imperial forts at Taku, while other British and French troops were defending the imperial city of Shanghai from an assault by the Taiping rebels. The period

was punctuated by two wars between England and France in alliance against China, one in 1856–58, the other in 1860.

But the dominating feature was the fact that, from 1842, there was a known moderate, published customs tariff in force; and that the foreigner paid his own duties as a tax and not as a part of the cost price, or a deduction from the price realised. Moreover, he had secured a reduction in the port charges on his ships from about ten dollars a ton to half a tael (two-thirds of a dollar) a ton. These facilities, together with the opening of five ports, the abolition of monopoly, and an appearance of protection to their trade, brought in by degrees numbers of competitors from the nations less adventurous than the English and Americans; but for some years the effect of this was not very marked.

The end of the first phase left the English and Americans in a predominating position at Canton; between them they had 95 per cent. of the trade, the English 63 and the Americans 32 per cent. In shipping, the Americans in the second phase took hold vigorously, and they originated a carrying trade. It had been the custom for ships to bring only goods for, and to carry only goods shipped by, their consignee; but the Americans began to load cargoes for the merchants generally. At the same time they improved their ships. The old East-Indiamen furnished the type of the British ships, even those of smaller size—bluff in the bow, heavy in the stern, good weight-carriers, splendidly seaworthy, but slow. The Americans improved on this, and invented the tea-clipper. In 1852, at Shanghai—which was already forging ahead of Canton—of the shipping entered, the British were 103 of 38,420 tons (average 375), the Americans 66 of 36,532 tons (average 553), and all other flags 13 of 3,213 tons. But the English had already, two years before, thrown away the crutches of their Navigation Laws, and without hesitation they accepted the challenge. In 1855 British shipping at Shanghai was 75,131 tons, American 56,792 tons, and all other flags 22,9.7 tons. In 1846, at Canton, the shipping entered was—British 88,880 tons, American 29,688, and all other flags 5,737 tons. In 1864 the shipping entered and cleared at all ports of China had a tonnage of 6,635,485 tons, of which the British was 2,862 214 tons, the American 2,609,390 tons, the several German states (Bremen, Hamburg, Hanover, Lübeck, Mecklenburg, Oldenburg, and Prusssia) together 580,570 tons, and all other flags 583,811 tons. These figures are startling; we have jumped at once from tens of thousands into millions. But the earlier figures give the tonnage of ships entered only, while in the later figures the tonnage entered is added to the tonnage cleared; the later figures should therefore be reduced to about a half for comparison. The ratio between British and American tonnage is still unaltered, and the several German flags assume respectable proportions. I have taken 1864 instead of 1867 in order that the German figures might refer to a time before the foundation of the North-German Federation, and so to give point to a quotation from Michie in his "Englishman in China":—

"Such a mosquito fleet was, perhaps, never before seen as that which flew the flags of the Hanse Towns and of Scandinavia on the China coast between 1850 and 1860; and many a frugal family on the Elbe, the Weser, and the Baltic, lived and throve on the earnings of these admirably-managed and well-equipped vessels ... the ships were run on a scale of economy and efficiency scarcely then dreamed of in England."

Herein lies the secret of this jump into millions; the foreigner had injected his shipping into the coasting trade, including the navigable rivers. The Chinese authorities considered that this trade should be reserved for Chinese shipping. While foreign ships were making their first intrusion into the Chinese coasting trade, the English law restricted the coasting trade of the United Kingdom to the British flag; and to this day American and Russian law reserves their own coasting trade, even for voyages from New York to San Francisco and from Odessa to Vladivostock, to their own flags. But the logic of events was too strong for the Chinese authorities. Foreign ships alone offered a speedy, safe, and insurable means of transport, they alone could protect their cargoes from pirates and rebels, and their services were everywhere in demand. For the long ocean voyage a sailing ship entered a Chinese port once a year; in the coasting trade, she entered a dozen or a score of times a year; and a steamer might enter from one to three hundred times, swelling the tables by her tonnage on each entry. In this trade the English and Americans both shared; and the Germans, with as yet inconsiderable trade in goods of their own, swarmed along the coast in brigs and barques of an average of 200 to 300 tons, the British average being 360 tons and the American 520 tons. The true significance of the shipping tables is seen when we compare the proportion of foreign tonnage engaged in foreign trade with that in the coasting trade;

but it must be noted that Hong Kong, a port of the Chinese commercial area, is necessarily treated as a foreign port. Taking the figures for 1872, the proportions were—

British—Foreign trade, 33 per cent.; coasting trade, 67 per cent.

American—Foreign trade, 6 per cent.; coasting trade, 94 per cent.

German—Foreign trade, 27 per cent.; coasting trade, 73 per cent.

Of the tonnage engaged in foreign trade, British was 70 per cent., American 11, German 9.

Of the foreign tonnage engaged in the coasting trade, British was 40 per cent., American 49, German 7.

But the peculiar status of Hong Kong unduly increases the figure for the British share in the foreign trade, and correspondingly reduces the British share in the coasting trade; still it is obvious that the English merchants were drowsy in developing their share in the coasting trade.

I will return later to the development of the trade in goods during the second phase, only dealing briefly with it here. The original purpose of the foreign traders in coming to China was to obtain tea and silk, and the import of foreign goods was only a secondary object, to provide the means of purchasing outward cargoes. I will therefore deal with the export trade first.

In *tea* China had a monopoly of supplying Western markets, practically through the whole of the second phase. At the end of the phase, in 1867, Japan and India together supplied 10 per cent. and China 90 per cent., but up to 1850 China supplied the whole. Of the total export, by sea and by land frontier, in 1828 and 1867 the distribution was as follows—

	1828. lb.	1867. lb.
United Kingdom . . .	27,301,790	134,999,100
English Channel for orders	...	10,497,600
Hong Kong	...	13,905,900
Russia	25,200,000	28,724,800
Continent of Europe . .	5,384,497	80,400
United States	6,875,676	25,887,100
Australasia, India, and Canada	2,441,794	16,982,000
	67,203,757	231,076,900

The table is significant. China was selling three and a half times as much tea. England and America were taking five times as much. Holland and the Hanseatic towns were taking practically none. Why? Because the English tax on tea had been reduced from its old rate of 96 per cent. to a shilling a pound, and smuggling was no longer profitable; and, in consequence, the English merchant supplied the whole of his natural market.

Raw silk, under the last years of the days of monopoly, had never exceeded 616,000 lb., but during the first three years after the English monopoly had been removed, rose to an average of 1,400,000 lb. a year. Then the Chinese monopoly was removed, and Shanghai, the natural outlet of the principal silk district, was opened to foreign trade; and in 1852 the export was 3,575,000 lb. Then the Taiping rebellion spread over the empire, cutting off the home demand for luxury products, and the supply increased until in 1858, in the midst of the war between China and England, the export was 9,628,600 lb.; and even in 1867, a year of depressed trade, it amounted to 5,040,000 lb., in addition to shipments of 504,000 lb. of woven silk.

In 1867 tea and silk of all kinds were valued at 53,408,400 taels; all other exports to foreign countries (including Hong Kong) were valued at 4,397,313 taels, making a total of 57,805,713 taels.

We have now to consider the method by which those exports were paid for. First in importance comes opium. The quantity known to have entered into Chinese consumption in 1867 was 86,530 piculs (103,000 cwt.), valued at 44,018,076 taels, which was the highest figure up to that date.

The next item is cottons, with the surprisingly high value of 14,617,268 taels. The end of our first phase left England receiving cotton cloth (nankeens) from China; in this second phase Manchester has been finding outlets for her products, and is now sending a few shiploads to supply China's millions. In the main, however, China still clothes her own people with her own cotton; and she even continues to import raw cotton from India, 336,072 piculs in 1867, valued at 5,164,392 taels, over a third of the value of English cotton cloth.

In the first phase the principal import from England was woollens, the value being about two million dollars ($1\frac{1}{3}$ million taels). At the end of the second phase this had increased to 7,391,226 taels, which represented the crest of a wave of expansion. Metals are unimportant: lead, 3,440 tons, for packing the exported tea; tin, 1,900 tons, for making brass; copper in bars and sheets, 1,335,000 lb., China herself supplying crude copper; quicksilver from California, 488,800 lb., for making vermilion and backing mirrors; iron and steel,

the gauge of modern civilisation, 7,000 tons. Besides raw cotton and foreign coal (113,430 tons), among "sundries" of sufficient importance to be enumerated, we find flints, ginseng, matches, needles, and window glass, total value 537,113 taels, as the only commodities imported from Europe or America. Other sundries are from the Southern Isles, or are Chinese produce passing through Hong Kong. The total value of all imports was 81,353,241 taels.

I will deal at the end of the third phase with the distribution of trade during the second phase; here I will deal only with the balance of trade. First I must note that the values given above are market values in the Chinese ports, and that, to reduce them to the one common denomination of value at moment of shipping and landing respectively, we must deduct from the value of imports the customs duty and charges estimated at 7 per cent., and must add to the value of exports the customs duty and 8 per cent. for charges. Corrected thus the values are—

Exports, 66,352,613 taels. Imports, 72,501,069 taels. Imports exceeded exports in 1867 by 6,148,456 taels. I shall deal with the balance of trade later.

In dealing with the first phase I went fully into the import of specie, and showed that, at its end, the trade had found the means of paying for the exports by imports, and had ceased to import silver; but meantime, through the whole of the phase, there had been a continuous monetary crisis, in the problem of "laying down the dollar" required for buying export cargoes. The second phase also had its monetary crisis, but it was of shorter duration, lasting from 1853 to 1857. On March 19th, 1853, the city of Nanking, a former capital of the empire, fell to the Taiping rebels. This destroyed 50,000 silk looms weaving industriously in that city; and the spreading success of the rebel armies reduced the whole of China to such a state of destitution as to destroy the demand for a luxury worn only by those who no longer possessed the means of buying it. Raw silk was thrown on the foreign market, and shipments from Shanghai, which had in 1852 reached the very high figure of 41,293 bales, amounted in 1853 to 58,319 bales, and continued to increase until, in 1858, they were 85,970 bales, valued at 29 million dollars (market price). Concurrently with this the demand for foreign products fell off; cotton and woollen fabrics (mostly English), which in 1867 were to be imported to the value of 30 million dollars, amounted in 1858 to no more than 9 million dollars; other commodities, too, were in reduced demand—except opium, which the Chinese would always take. In that year the adjusted value of all exports at Shanghai was about 50 million dollars, and of imports—for opium 15 million, other commodities 19 million, total 34 million dollars; leaving a deficit of 16 million to be covered, besides the cost of maintaining the shipping and the merchant's establishments. Nor was this all. In times of stress the natural instinct of the Asiatic is to hoard—to dig a hole in his back garden and bury in it his metallic treasure; and when the dollars disbursed for silk and tea once came into Chinese hands they were hoarded and no longer returned to the channels of trade. The stringency was extreme. The foreign traders scrambled for every Carolus dollar that they could lay their hands on in every market of the world; Europe was scraped for dollars until it was scraped dry; dollars were poured into Shanghai—a million a month at first, ultimately 20½ millions in 1856, and 18 millions in 1857—but they disappeared into the void as a stream of water is sucked into the thirsty sands of a desert.

The Carolus dollar had an intrinsic value of 4*s.* 2*d.*, but for buying exchange its normal value was from 4*s.* 6*d.* to 4*s.* 10*d.*, the difference representing the cost, including interest, of carrying them to Shanghai. In 1852 the current rate for six-months' bills on London did not exceed 4*s.* 8*d.*, which was 12 per cent. premium over the intrinsic value, until the end of the year, when it rose to 22 per cent. After the fall of Nanking it rose rapidly, until before the end of September, 1853, it was at no less than 86 per cent. premium. It fell again, but never below 50 per cent. premium, and oscillated between 50 and 65 per cent. premium for three years, until in 1856, for shipping the tea and silk of that year, the rate rose again to 86 per cent. premium. The situation became intolerable, and, in the end, the foreign traders in Shanghai were driven to abandon their standard of currency which was represented by a coin, the dollar, and for it to substitute a standard of Chinese currency which was represented by no coin, but only by ounces (taels) of silver. The anomalous situation is shown by the fact that, on a designated day in April, 1857, the banks at Shanghai credited their customers with a tael containing 525 grains of fine silver, in exchange for each dollar,

containing 374½ grains, standing to their credit.

The first phase was the period of the lumbering Indiaman, carrying her own mail advices; when the trader had to foresee the demand of the market next year, and to contract this season for his next season's tea. My second phase was the period of the swift sailing tea-clipper, but her advices were now sent by a monthly steamer; indents for imports could now be filled in seven months, and tea and silk were bought on the strength of market advices only sixty to eighty days old. The third phase, that from 1867 to 1911, the end of the Empire, to which I have come, was the period of the Suez Canal; the period in which the trans-oceanic trade was carried by steamer; with market quotations and orders sent by the cable, which was opened through to Shanghai in 1871; and with the merchant no longer needing long foresight, no longer depending on his sagacity in providing for a distant future, but taking orders to buy or sell, and executing them on commission. Each of the three phases was characterised by its own money difficulty; and, before proceeding to analyse the trade of the third phase, I will describe its currency problem.

The currency of China is the tael, or Chinese ounce, of silver; but there are in China hundreds of different taels, varying according to different weights of the tael and different standards of silver. The first traders traded, and bought exchange, in Spanish dollars. In 1857, as I have just said, the foreign traders at Shanghai adopted the tael as their currency; but those in South China continued to buy and sell goods and bills for dollars—at first Mexican, but afterwards of some other mints—but always by weight and not by count, and always rated by the intrinsic value of the silver content. The course of exchange was therefore affected by two factors: the supply and demand for bills to be negotiated, as in all exchange markets; and, for exchange between China and gold-using countries, the quotation for silver in terms of gold.

Originally all countries based their currency on silver, and this continued for many centuries. Early in the nineteenth century—only one hundred years ago—England abandoned silver and based her exchanges solely on gold. She was only one among the many nations, and her demonetisation of silver did not serve to create any serious alteration in the relative market values of silver and gold; but in 1873 the brand-new German Empire, adopting a brand-new currency, based it solely on gold, and in the same year the United States, partly through inadvertence, also demonetised silver. The sensitive bullion market felt the disturbing influence at once, and the political financiers hastened to get under cover from the threatening storm; by the end of the century, 1900, every commercial nation had adopted either the gold standard or the limping standard—every one except China.

In 1873 the exchange value of Chinese currency began to fall, and (taking 6*s*. 8*d*. per customs tael as par, or 100 per cent.) by 1879 it had fallen to 84 per cent. In 1885 a further fall began, and in 1889 the exchange value was only 71 per cent. In 1891 the fall became more rapid, and in 1894 the value was only 48 per cent., and the lowest level was reached, at 36 per cent., in 1903. In thirty years the currency of the whole empire had lost close on two-thirds of its international exchange value. But the loss in purchasing power of the tael was not the worst feature, as prices can be adjusted to a depreciated currency. Far worse than this were the frequent fluctuations in the exchange. Taking, for example, the years 1903 and 1904, besides the daily oscillations, there were nine major movements between extreme points, ranging from 2 to 16 per cent., of alternate rise and fall; during the two years the highest point was 30 per cent. greater than the lowest point. The uncertainty turned all trade into gambling. Two months might pass while the merchant's goods were on the steamer, three months between the date of a telegraphed order and the arrival of the goods at their market; and in those two or three months exchange might rise or might fall 10, or 12, or 16 per cent., while the merchant worked on a margin of 1, or 2, or 3 per cent. Even if the importing or exporting merchant, the foreigner, prudently settled his exchange simultaneously with his indent, the gamble was only transferred to the Chinese buyer of his imports, or the holder of his Chinese produce on the foreign market. To make matters worse, exchange has recovered, and to-day, in 1919, the silver rate, which in 1903 was at 36 per cent. of its old par value, is again at full 100 per cent.; and this recovery constitutes the exchange problem of the present time.

I should note, as a further complication, that in 1904 silver, the currency of the wholesale trade, had sunk to 68 per cent. of its 1873 value in terms of copper, the currency of the retail

dealer and of the producer and consumer; and further, that the economist and the statistician must deal with the fluctuations in the exchange values of gold, of silver, of copper, and of paper, when dealing with the trade of China. I think I need say nothing more to show the complexity of the subject, and the impossibility of doing anything more than give this outline in a paper on the whole trade of China.

During this third phase, from 1867 to 1911, the shipping engaged in the China trade increased from (entries and clearances) 6,635,485 tons in 1864 (practically no Chinese shipping) to 86,206,497 tons (including 17,277,407 tons of Chinese shipping coming under the foreign customs); the shipping under foreign flags was then 68,929,090 tons, over ten times the figures of 1864. Of the total of 1912, of all flags, 26,071.482 tons were engaged in the foreign trade (including Hong Kong), and 60,135,015 tons in the coasting trade. In the two years the tonnage was divided between the different flags as follows:—

	1864.	1912.
British	2,862,214	38,106,732
American	2,609,390	715,001
German	580,570	6,171,684
Japanese	756	19,913,385
Other foreign	527,967	4,022,288
Chinese	64,588	17,277,407
	6,635,485	86,206,497

In percentage the British flag has held its own, and absolutely has increased to thirteen times its old tonnage. The American flag has disappeared from the coasting trade, and is shown only on a few mail steamers. The German flag fills a space in the table so large as to create a good-sized void to-day. The Japanese have taken the Americans' place as second in the race. And the Chinese are again doing a portion of their own coasting trade, but now in steamers to the extent of three-fourths of the tonnage shown in the table.

We have now to consider the development of the export trade in the third phase.

Tea had a chequered career. Originally the most important element in the export trade. constituting 60 per cent. of the English trade in the first phase, it held its own through the second phase, and, in 1867, it contributed 59 per cent. to the total value of all Chinese produce exported. In 1905 tea contributed only 11 per cent. to the value of exports, partly due to a great development in the trade in "sundries" (*i.e.* commodities other than tea and silk), but partly also to an absolute loss of the tea trade. For several centuries China had a monopoly in supplying the world with tea; India entered the market experimentally in 1838, and in 1852 shipped 232,000 lb. (1,740 piculs) to England; Japan was thrown open in 1858; Ceylon and Java took up the industry about 1883; and in 1905 China maintained her supremacy only in the Russian market. The following table shows her downward course in supplying Western markets:—

PROVENANCE OF TEA EXPORTS.

	1867.		1886.		1905.	
	Piculs.	Per cent.	Piculs.	Per cent.	Piculs.	Per cent.
China—Tea leaf	1,248,256	85·8	1,846,989	58·6	839,173	17·8
China—Brick tea	65,311	4·5	370,212	11·7	530,125	11·2
Japan	89,544	6·1	275,823	8·8	298,422	6·3
India	53,130	3·6	551,078	17·5	1,617,380	34·3
Ceylon	..	..	60,833	2·0	1,238,260	26·4
Java	..	..	44,010	1·4	191,025	4·0
	1,456,241		3,148,945		4,714,385	

In 1867 China supplied the Western world, including Asiatic Russia, with 90 per cent. of its consumption of tea, and in 1905 with only 29 per cent., including both the highly priced tea leaf and the commoner brick tea; but in 1867 tea leaf constituted 95 per cent. of the Chinese export, and in 1905 only 61 per cent. Markets have been lost as well. In 1867 the import into England came 95 per cent. from China, and 5 per cent. from India; in 1905 of the consumption of the United Kingdom, only 2½ per cent. came from China. Of the import into the United States in 1867, China supplied 68 per cent. and Japan 32 per cent., while in 1905 China supplied 40 Japan (including Formosa) 35, and other sources 25 per cent. Australia in 1867 took all her tea from China; in 1905, of a consumption of 246,750 piculs (33 million lb.) China supplied less than 2 per cent. Russia, which in 1867 took all her tea from China, still gives China her principal market; in 1906 (war in 1905), of China's export of tea leaf and brick tea, 67 per cent. was declared for Russia, including Siberia; and in 1906, of the Russian

consumption of tea leaf (118½ million lb.) 60 per cent., and of brick tea (86½ million lb.) 92 per cent. came from China.

Silk and its manufactures in 1867 came next to tea, the value being 33 per cent. of that of all exports; in 1908 silk had risen to first place with 30 per cent. Of raw silk China has maintained its percentage in supplying the Western markets, and in doing so has more than trebled her quantities, as shown in the following table:—

PROVENANCE OF SILK.

	China.	Japan.	India.	Levant.	France and Italy.	Total.
1867. Metric tons	2,338	633	627	..	2,939	6,537
1877. ,, ...	3,548	1,101	672	621	2,448	8,390
1887. ,, ...	3,870	2,217	528	738	4,535	11,888
1898. ,, ...	6,945	3,122	275	1,479	4,877	16,698
1908. ,, ...	7,975	7,531	250	2,693	5,551	24,000

During the first and second phases raw silk, except the quantities required for the United States, went to London and was there bought for the French and Italian weavers; during the third phase the Continental trade bought its silk in China and imported it direct, its value constituting at the end of the third phase 85 per cent. of all exports to France and Italy. In woven silks China has lost her premier position among the Asiatic nations; in 1867 Chinese woven silks exported were valued at 2½ million taels, while the Japanese export was inconsiderable; in 1906 the figures were, China 11 million taels, Japan 26 million taels.

Sundries—the old-time China merchant's "chow-chow cargo"—in 1867 constituted 8 per cent. of all exports; in 1905 they had risen in importance to 58 per cent., and this vast development was due solely to the energy of the foreign traders, the Chinese being apathetic.

[*The remainder of the paper and the discussion will be printed in the next number of the "Journal."*]

THE DEVELOPMENT OF THE TEXTILE INDUSTRIES.

The Dye Supply.—Deliveries of dyestuffs under the reparation clauses of the Peace Treaty are relied on to give manufacturers a freer hand in the use of colour than they have had for five years past. Nobody has gone without dyes, but the selection has been restricted, and of necessity those colours which have been scarcest have had to be sparingly used. The coloured stripes in men's shirtings are widening now that producers feel sure of larger supplies of the so-called vat colours. These are dyes developed upon the fibre, and valuable not so much for any brilliance of shade as for their fastness to all the trials of the wash-tub. The stripes have been narrow hitherto because makers of shirtings did not dare to employ two threads of coloured yarn if they could make shift with one. Exceptionally fast colours and those of extraordinary brightness and delicacy have been the most difficult to procure. The latter are used not solely as self-colours, but to enliven shades produced by the mixture of less fine colour stuffs.

Points of Perfection.—The austerer beauties of textile art excite less notice than do the pronounced qualities of the more ambitiously decorative goods. There is skill of course in the nice placing and colouring of a simple stripe, although its exercise is taken very much for granted. The purity of a white or the precise degree of sheen upon a surface may not actually escape attention, but these characteristics are difficult to appraise, and it is possible that nobody but the men who have done the work know all that it has cost in the way of research, effort and ingenuity to reproduce them an infinite number of times over. Simple-looking triumphs always run the risk of neglect, but justice cannot be done to textile skill without paying regard to minutiæ which barely lend themselves to exact description. One might be hard put to it to explain, for example, wherein the best cotton goods of to-day improve upon those of ten, twenty or thirty years ago. But the fact of an improvement is not to be denied, and it is evident that such advance as there has been resides in a series of almost ultra-microscopical fine points.

A New Material.—A new cotton fabric produced by the Calico Printers' Association under the name of Sheenore marks a real advance in the production of fancy cotton goods. In texture the cloth resembles the printed voiles now so largely worn, and it is printed albeit only upon the warp threads. The process of warp or *chaine* printing, long followed upon silks and upon heavy cotton goods has not hitherto been found practicable upon light cottons. The operation of printing has been found to make the warp tender, or short of strength, but that is certainly not the case in the instance under notice. The weft, or crossing threads, are dyed to a shade contrasting with the bright colours used in printing upon the warp. After weaving and finishing the effect is a "shot," but not a plain shot. The printed design peers from beneath the weft with greater or less prominence according to the angle made with the eye. It follows that a remarkably lively appearance is made with the

fabric draped and in motion, and it is safe to say that nothing like it has been produced in cotton before. The article is by no means cheap, and perhaps can never be made very cheaply, but it is not seriously less notable upon that account, and it is safe of its public.

Printed Silks.—Printed designs are in for a new vogue next year, and it appears to be settled that printed silks will be more seen than for twenty years past. It is not only light silks that are being printed but heavy satins and brocades as well, and they are being treated in rather violent colours and sometimes in sprawling designs. Large preparations have been made, and the demand will be met for everything from black or blue foulard with white spots up to satins printed in gold. The designs are not all eccentric, but some of those produced in Lyons run to unchastened extremes and will be none the worse for discreet use after reaching the dressmaker's hands.

Output.—The reduction of working hours in this and other countries to forty-eight per week would not yet seem to have evoked any corresponding increase in the output per hour. There has presumably not been time yet to make the readjustments which will be required, and there has been no great pressure of adversity to stimulate invention. Manufacturers are doing almost too well in the matter of profits and their employees have received compensation for their sacrifice of output. Normal incentives to get the last ounce out of the machines can scarcely be said to exist, but the desirability of getting the old output from the new schedule of hours is not actually forgotten. It is not especially to the good of the industry that a low rate of production should be as profitable as at present, but there may be some consolation in the knowledge that the case is much the same elsewhere as in our own country.

The Price of Clothing.—There are few visible prospects of cheaper clothes in 1920. Short of some unforeseeable event they will rule dearer rather than cheaper, and a fall in prices is deferred apparently to the Greek Kalends. Clothing is dearer in the European countries and America than here, and reports from Germany show that even a shoddy suit costs 350 marks. It looks as though a large part of the world would be reduced to the uneconomical necessity of clothing itself in rubbish, despite the accumulation of good wool existing in one part of the world or another. Already there are in the shops of this country suits for men made out of cloths that would hardly have been used for a servant girl's costume in 1914, and others made from cloths that would certainly have found no other use than in the very cheapest of little boys' suits. It is wasting energy to put into these products virtually the same efforts as would make a suit which would be satisfactory in wear. Prices are unconscionably high, but it is still the case that money is to be saved by paying well up to the market level. Proportionately, good clothes have not advanced as much as poor ones, and rubbish remains rubbish be the sale price what it may.

Causes of Dearness.—It has been abundantly shown that proceedings taken against retail distributors accused of profiteering have no influence at all upon the prices at which retailers buy. The beginnings of the dearness of clothes lie far back. It is apparent that the raw materials of textile industry fetch high prices in the open market, but not such prices as would explain the eventual cost to the consumer of finished goods. Wages, it is true, have doubled, or more than doubled, but neither do they explain more than a little of the increase in cost. The first marked advance in cost begins with the conversion of raw material into the semi-manufactured yarn, and it is apparent that spinners receive anything up to fifteen times their pre-war margin. The fact occurs not as the result of any conspiracy between them but as the consequence of the strength of demand upon their limited facilities. The weaving manufacturer pays dearly for his yarn and is able in existing circumstances to exact more than his normal profit. At every stage—and it is worth remembering that, in course of their progress, goods pass through about half-a-dozen sets of hands—something more than a starvation payment is exacted. The increase is a cumulative one and it does not all remain in private pockets. In fixing prices the several parties all have the Excess Profits Duty in view, and the fact that this duty is levied time and again upon the one set of goods has decidedly not been without influence in producing the state of affairs of which consumers with fixed incomes legitimately complain.

OBITUARY.

JOHN DIBBLEE CRACE.—The Society has lost one of its oldest Fellows by the death of Mr. John Dibblee Crace, which occurred on the 18th inst. at the age of eighty-one. Mr. Crace was elected a member of the Society in 1862. In 1888 he read a paper on "The Decorative Use of Colour" before the Applied Art Section. He frequently attended the Society's meetings and took part in the discussions.

Mr. Crace was the fifth of his family in direct descent to practise the art of decoration. When sixteen years old he joined his father in business, but he continued his education by various visits to foreign countries. He designed the decorative colouring of the new portions of the National Gallery, the "Victoria Hall" in Leeds, and the Indian Room at the Imperial Institute. He was deeply interested in education on the technical side of decorative art, and took an active part in founding travelling studentships. He visited Palestine in 1869, and soon after his return he

became connected with the Palestine Exploration Fund, acting first as a member of its council, and finally as its hon. secretary.

He published a book on "The Art of Colour Decoration," and he was throughout his life an indefatigable sketcher of very considerable talent. He also occasionally exhibited small pictures at the Royal Academy.

He was Master of the Painter Stainers' Company in 1884, a post which his father had filled in 1879, and his grandfather in 1851.

GENERAL NOTES.

Education in India.—The Joint Select Committee on Indian reforms briefly refer in their report to education in India. The question, they say, is far too large for them to make any attempt to deal with it adequately. They have accepted the recommendation of the "Functions Committee" that, subject to certain reservations about the universities, the responsibility for the whole field of education in each province should be transferred to the Ministers to be called into existence by the measure now before Parliament. They attach much importance, however, to the educational advancement of the "depressed and backward classes," and trust that the subject will receive special attention from Ministers. They are also impressed by the advantage of Boards such as Sir Michael Sadler has advised in Bengal for the assistance of Ministers in controlling the different grades of education.

Transvaal Tobacco.—Steps are being taken, according to *United Empire*, to establish an oversea market for Transvaal tobacco. Large areas of suitable land are still available in the north-western Transvaal, while the completion of the big Crocodile River dam at Hartebeeste Poort, which is being constructed by the Government at a cost of over £1,000,000, and should be finished in two or three years' time, will add some thousands of acres more to the area already given up to tobacco. A certain amount of South African tobacco was shipped to Europe and other parts of the world during the war for the use of the troops, but before then the quantity exported was almost negligible. Ever since the South African War of 1899-1902 small quantities of the better-known brands have been sent to England, but now that the production has so increased as to have a considerable surplus over and above local requirements, the question of developing an export trade has arisen. The total tobacco production of the Union at the present time amounts to about 10,000,000 lb. per annum, and of this the local market absorbs about 8,000,000 lb.

Trinidad Fustic Wood.—An important industry appears to have developed in Trinidad last year in supplying to the United States fustic wood, a product of the local forests, and used as a yellow dye, chiefly in connection with textile goods. The Trinidad product is claimed to be of superior dye strength to that from Mexico, whence most of the fustic sent to the United States is said to have been obtained. According to the United States Consul in Trinidad, the declared export returns of his office show that Trinidad exported, during 1918, 168,000 lb. of fustic wood to the United States, to the value of 1,880 dollars, and during the first three months of 1919 this quantity was very nearly equalled. Fustic wood, sometimes known as Bois d'Orange, is not only well known in Trinidad as a dye wood, but also as an excellent timber of unusual durability. Many of the trees are 13 to 14 ft. in girth, but a fair average would be about 5 ft.; a tree of this size would give from 3,000 to 5,000 lb. of the commercial product. A fair average cost of the product in the vicinity of the forest in which it is cut, including the cost of the trees, which is paid to the Government, is about 10 dollars a ton of 2,240 lb. This prime cost, however, is seriously augmented by the heavy cost of transporting the logs to Port of Spain, so that the average cost of production is brought up to about 25 dollars per ton. In the Government forests all along the southern coast of Trinidad, fustic trees appear to be in great abundance. They are also found in the smaller island of Tobago, just north of Trinidad. Fustic wood is also valuable to local wheelwrights for naves and felloes, and probably fine furniture might be made from it.

Naval Direction-finding Stations.—The Canadian Department of Naval Service has established on the east coast of Canada four direction-finding stations which should prove of great value to vessels unable to determine their position owing to fog. These stations are at Cape Sable, at the mouth of Halifax Harbour, at Cape Canso, and Cape Race, Newfoundland. From any of these a vessel equipped with wireless can obtain a bearing while at a distance of several hundred miles from the coast.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday afternoons, at 4.30 p.m.:—

December 3.—John Westall Pearson, Chairman and Director, British Oil and Cake Mills, "The Oil Seed Crushing Industry." The Right Hon. Lord Lamington, G.C.M.G., G.C.I.E., will preside.

December 10.—Sir Oliver Lodge, D.Sc., Sc.D., LL.D., F.R.S., "Some Possible Sources of Energy." (Trueman Wood Lecture.) The Hon. Sir Charles Algernon Parsons, K.C.B., LL.D., D.Sc., F.R.S., will preside.

December 17.—Constantine Grunewald, late Chief of Intelligence Department, Russian

Ministry of Trade and Industry, "The Present Economic Position of Russia, and some Aspects of its Future Development."

COLONIAL SECTION.

Tuesday afternoon, at 4.30 p.m. :—

DECEMBER 9.—SIR EDWARD DAVSON, President of the Associated West Indian Chambers of Commerce, "Problems of the West Indies." LIEUT.-COLONEL L. S. AMERY, M.P., Under-Secretary of State for the Colonies, will preside.

INDIAN SECTION.

Thursday afternoon, at 4.30 p.m.

DECEMBER 18.—P. J. HARTOG, C.I.E., M.A., Member of the Calcutta University Commission, 1917-1919, "Some Problems of Indian Education."

Papers to be read after Christmas :—

AIR-COMMODORE EDWARD MAITLAND, C.M.G., D.S.O., "The Commercial Future of Airships."

SIDNEY PRESTON, C.I.E., "English Canals and Inland Waterways."

BRIGADIER-GENERAL SIR HENRY P. MAYBURY, K.C.M.G., C.B., M.Inst.C.E., "Road Transport."

CHARLES H. SHERRILL, "Stained Glass."

ALFRED E. HAYES, General Secretary, English Language Union, "The English Language and International Trade."

JAMES CURRIE, C.M.G., Ministry of Labour (Training Department), late Principal, Gordon Memorial College, Khartoum, "Industrial Training."

LADY INGLEFIELD, President, Buckinghamshire Lace Association (North Bucks and Bedfordshire), "The Hand-made Lace Industry."

GRAILY HEWITT, "Rolls of Honour."

ALFRED H. POWELL, "Ancient Cottages and Modern Requirements." The Right Hon. EARL FERRERS will preside.

CHARLES CROWTHER, "The Arts and Crafts of Japan" (with examples from the author's private collection).

SIR CECIL HERTSLET, late H.M.B. Consul-General for Belgium, "The Ruin and Restoration of Belgium." EMILE CAMMAERTS will preside.

WILLIAM CRAMP, D.Sc., M.I.E.E., "Pneumatic Convoying Plants, with special reference to the Transport of Grain."

L. GASTER, "Industrial Lighting in its relation to Efficiency."

H. M. THORNTON, "Gas in relation to Industry and Housing."

LIEUT.-COMMANDER NORMAN WILKINSON, R.N.V.R., O.B.E., R.O.I., R.I., "Naval Camouflage."

BRIGADIER-GENERAL LORD MONTAGU OF BEAULIEU, C.S.I., "Roads and Transport in India."

SIR GEORGE CUNNINGHAM BUCHANAN, K.C.I.E., M.Inst.C.E., "The Ports of India: their Administration and Development."

SIR JOHN HUBERT MARSHALL, C.I.E., M.A., Litt.D., F.S.A., Director-General of Archæology in India, "Recent Archæological Discoveries in India."

SIR VALENTINE CHIROL, "The Enduring Power of Hinduism." (Sir George Birdwood Memorial Lecture.)

SIR FRANCIS WATTS, K.C.M.G., D.Sc., Imperial Commissioner of Agriculture for the West Indies, "Tropical Departments of Agriculture, with special reference to the West Indies." LIEUT.-COLONEL SIR DAVID PRAIN, C.M.G., C.I.E., LL.D., F.R.S., Director of the Royal Botanic Gardens, Kew, will preside.

INDIAN SECTION.

Thursday afternoons, at 4.30 p.m. :—

January 15, February 19, March 18, April 15, May 20.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 p.m. :—

February 3, March 2, May 4.

CANTOR LECTURES.

Monday evenings, at 8 p.m. :—

JOHN THEODORE HEWITT, M.A., D.Sc., Ph.D., F.R.S., Emeritus Professor of Chemistry, East London College, "Synthetic Drugs." Three Lectures.

Syllabus.

LECTURE I.—DECEMBER 1.—Introductory—Simple aliphatic compounds—Alcohols, formaldehyde, paraldehyde—Ketones and derivatives such as sulphonal—Veronal and other compounds derived from urea—Non-aromatic cyclic compounds, *e.g.* the derivatives of Borneol.

LECTURE II.—DECEMBER 8.—Phenol, salicylic acid and related substances—Derivatives of aromatic amines and aminophenols, *e.g.* phenacetin—Compounds of heterocyclic structure, antipyrine, flavine, etc.

LECTURE III.—DECEMBER 15.—Modified alkaloids, *e.g.* heroin, euquinine—Organic compounds of arsenic (atoxyl, salvarsan), antimony, mercury and other metals—Conclusion.

CAPTAIN H. HAMSHAW THOMAS, M.B.E., M.A., F.G.S., Fellow of Downing College, Cambridge, and formerly of the Royal Air Force, "Aircraft Photography in War and Peace." Three Lectures.

January 19, 26, February 2.

CHARLES FREDERICK CROSS, B.Sc., F.R.S., F.C.S., "Recent Research in Cellulose Industry." Three Lectures.

February 16, 23, March 1.

WALTER ROSENHAIN, B.A., D.Sc., F.R.S., Superintendent, Department of Metallurgy and Metallurgical Chemistry, National Physical Laboratory, "Aluminium and its Alloys." Three Lectures.

April 12, 19, 26.

ARTHUR THOMAS BOLTON, F.R.I.B.A., F.S.A., Curator, Soane Museum, "The Decoration and Architecture of Robert Adam and Sir John Soane, 1758-1837." Three Lectures.

May 3, 10, 17.

JUVENILE LECTURES.

Wednesday afternoons, at 3 p.m.:—

LOUGHNAN PENDRED, M.I.Mech.E., Editor of *The Engineer*, "Railways and Engines."

January 7, 14.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, DECEMBER 1...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Dr. J. T. Hewitt, "Synthetic Drugs." (Lecture I.)

Swiney Lectures, Imperial College of Science, South Kensington, S.W., 5.30 p.m. Dr. J. D. Falconer, "The Geology and Mineral Resources of the British Possessions in Africa." (Lecture X.)

Royal Institution, Albemarle-street, W., 5 p.m. General Monthly Meeting.

Engineers, Society of, at the Geological Society, Burlington House, W., 5.30 p.m. Captain R. Twelvetrees, "Mechanical Transport in the War."

Chemical Industry, Society of (London Section), at the Chemical Society, Burlington House, W., 8 p.m. 1. Mr. A. Henning, "Ethyl Chloride." 2. Mr. C. E. Barrs, "The Influence of Impurities in Lead when it is heated with Concentrated Sulphuric Acid."

Geographical Society, 135, New Bond-street, W., 8.30 p.m. Mr. H. W. Fox, "Development of Transport on the Great Lakes of Africa."

British Architects, Royal Institute of, 9, Conduit-street, W., 8 p.m.

Electrical Engineers, Institution of (Western Centre), Technical College, Bristol, 7 p.m. Address by Mr. W. A. Chamen.

TUESDAY, DECEMBER 2...Industrial League, Council Chamber, Guildhall, E.C., 4.30 p.m. Sir G. Paish, "League of Nations."

Electrical Engineers, Institution of (North-Western Centre), 17, Albert-square, Manchester, 7 p.m. Discussion on "Electricity Supply."

University of London, University College, Gower-street, W.C., 5.30 p.m. Mr. J. H. Helweg, "Holberg and Ewald." (Lecture V.)

Civil Engineers, Institution of, Great George-street, S.W., 5.30 p.m. Discussion on Mr. M. F. Wilson's paper, "Admiralty Harbour, Dover."

Photographic Society, 35, Russell-square, W.C., 7 p.m. Mr. A. H. Lisett, "Lantern-slide Making."

Horticultural Society, Vincent-square, Westminster, S.W., 3 p.m.

Marine Engineers, Institute of, The Minories, Tower-hill, E., 6.30 p.m. Address by the President.

WEDNESDAY, DECEMBER 3.—ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Mr. J. W. Pearson, "The Oil Seed Crushing Industry."

Automobile Engineers, Institution of, at the Institution of Mechanical Engineers, Storey's-gate, S.W., 8 p.m. Mr. E. N. Duffield, "Car Designs and Car Usage from the Point of View of the Majority of Owner Drivers."

Swiney Lectures, Imperial College of Science, South Kensington, S.W., 5.30 p.m. Dr. J. D. Falconer, "The Geology and Mineral Resources of the British Possessions in Africa." (Lecture XI.)

Geological Society, Burlington House, W., 8 p.m.

Public Analysts, Society of, at the Chemical Society, Burlington House, W., 8 p.m.

Oriental Studies, School of, Finsbury-circus, E.C., 5 p.m. Mr. L. Binyon, "The Art of Asia." (Lecture III.)

United Service Institution, Whitehall, S.W., 3 p.m. Air-Commander H. R. Brooke-Popham, "The Air Force."

Electrical Engineers, Institution of (South Midland Centre), The University, Birmingham, 7 p.m. Mr. G. L. Addenbrooke, "Dielectrics."

Literature, Royal Society of, 2, Bloomsbury-square, W.C., 5.15 p.m. Professor W. L. Courtney, "Some Dramas of D'Annunzio."

Royal Archæological Institute, at the Society of Antiquaries, Burlington House, W., 4.30 p.m. Mr. G. C. Druce, "The Elephant in Mediæval Legend and Art."

Public Health, Royal Institute of, 37, Russell-square, W.C., 4 p.m. Mr. R. Unwin, "Town Planning—Its Influence on the Health and Well-Being of the Citizen."

University of London, University College, Gower-street, W.C., 5.30 p.m. Mr. I. C. Grondahl, "Holberg and Wessel." (Lecture V.)

6.15 p.m. Dr. J. C. Stamp, "Fundamental Principles of Taxation in the Light of Modern Developments." (Lecture V.)

THURSDAY, DECEMBER 4...University of London, University College, Gower-street, W.C., 5.30 p.m. Professor A. Cippico, "La Poesia di Giovanni-Pascoli." (Lecture VI., in Italian.) Mr. I. Bjorkhagen, "Selma Lagerlof." (Lecture V.)

Royal Society, Burlington House, W., 4.30 p.m.

Child Study Society, at the Royal Sanitary Institute, 90, Buckingham Palace-road, S.W., 6 p.m. Rev. W. F. Cobb, "Religion in Education."

Chemical Society, Burlington House, W., 8 p.m. 1. Mr. H. Henstock, "X Di-phenanthryl." 2. Messrs B. D. Steele and H. G. Denham, "A New Sulphuretted Hydrogen Generator."

FRIDAY, DECEMBER 5...Technical Inspection Association, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 7.30 p.m.

Swiney Lectures, Imperial College of Science, South Kensington, S.W., 5.30 p.m. Dr. J. D. Falconer, "The Geology and Mineral Resources of the British Possessions in Africa." (Lecture XII.)

University of London, University College, Gower-street, W.C., 8 p.m. Professor G. D. Hicks, "An Introduction to Modern Philosophical Thinking." (Lecture V.)

Philological Society, University College, Gower-street, W.C., 8 p.m. Mr. H. O. Coleman, "Existing Parts of Speech-Distinctions have no Logical Basis."

Geologists Association, University College, Gower-street, W.C., 7.30 p.m. Mr. W. B. R. King, "Geological Work on the Western Front."

Journal of the Royal Society of Arts.

No. 3,498. VOL. LXVIII.

FRIDAY, DECEMBER 5, 1919.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

MONDAY, DECEMBER 8th, at 8 p.m. (Cantor Lecture.) JOHN THEODORE HEWITT, M.A., D.Sc., Ph.D., F.R.S., Emeritus Professor of Chemistry, East London College, "Synthetic Drugs." (Lecture II.)

TUESDAY, DECEMBER 9th, at 4.30 p.m. (Colonial Section.) SIR EDWARD DAVSON, President of the Associated West Indian Chambers of Commerce, "Problems of the West Indies." LIEUT.-COLONEL L. S. AMERY, M.P., Under-Secretary of State for the Colonies, will preside.

WEDNESDAY, DECEMBER 10th, at 4.30 p.m. (Trueman Wood Lecture.) SIR OLIVER LODGE, D.Sc., Sc.D., LL.D., F.R.S., "Some Possible Sources of Energy." The Hon. SIR CHARLES ALGERNON PARSONS, K.C.B., LL.D., D.Sc., F.R.S., will preside.

Further particulars of the Society's meetings will be found at the end of this number.

COLONIAL SECTION.

A meeting of the Colonial Section Committee was held on Monday, December 1st. Present:—

Lord Blyth (Chairman of the Section) in the chair; R. E. Brounger; The Hon. Sir John A. Cockburn, K.C.M.G.; Edward Dent, M.A.; Major E. H. M. Leggett, R.E., D.S.O.; and George Wilson, C.B.; with G. K. Menzies, M.A. (Secretary of the Society), and S. Digby, C.I.E. (Secretary of the Section).

CANTOR LECTURE.

On Monday afternoon, December 1st, DR. JOHN THEODORE HEWITT, F.R.S., Emeritus Professor of Chemistry, East London College, delivered the first lecture of his course on "Synthetic Drugs."

The lectures will be published in subsequent numbers of the *Journal*.

THIRD ORDINARY MEETING.

Wednesday, December 3rd, 1919; The Right Hon. LORD LAMINGTON, G.C.M.G., G.C.I.E., in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Agar, Alfred, Belfast.
Barton, Alfred Danell, A.M.I.A.E., London.
Bishop, Edwin Kelsham, London.
Briggs, Roland Hunter, A.M.I.Mech.E., Harrow-on-the-Hill, Middlesex.
Britten, William Robert James, Horley, Surrey.
Brown, Alexander, Belfast.
Gill, Geoffrey M., London.
Gooby, Alfred H., London.
Hart, James Connorton, M.P.S., London.
Ide, H. W. F., London.
Longcroft, Cecil J., London.
Newnes, Sir Frank, Bt., London.
Pearson, John Westall, London.
Russell-Cotes, Sir Merton, J.P., Bournemouth.
Smout, Arthur John Griffiths, A.I.C., A.I.M.M., F.C.S., King's Heath, Birmingham.
Turrell, Frank William, King's Heath, Birmingham.

The candidates proposed at the opening meeting on November 19th, of whom a list was published in the *Journal* of November 21st (pp. 2 and 3), were duly elected Fellows of the Society.

A paper on "The Oil Seed Crushing Industry" was read by Mr. JOHN WESTALL PEARSON, Chairman and Director of the British Oil and Cake Mills.

The paper and discussion will be published in the next number of the *Journal*.

JUVENILE LECTURES.

The usual short course of lectures adapted to a juvenile audience will be delivered on Wednesday afternoons, January 7th and 14th, 1920, at 3 p.m., by Mr. LOUGHNAN PENDRED, M.I.Mech.E., Editor of *The Engineer*, on "Railways and Engines."

Special tickets are required for these lectures. They can be obtained on application to the Secretary.

A sufficient number of tickets to fill the room will be issued to Fellows in the order in which applications are received, and the issue will then be discontinued. Subject to these conditions, each Fellow is entitled to a ticket admitting two children and one adult. Fellows who desire tickets are requested to apply for them at once.

LIST OF FELLOWS.

The new edition of the List of Fellows of the Society is now ready, and copies can be obtained on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

SECOND ORDINARY MEETING.

BRITISH TRADE IN CHINA.

By H. B. Morse, LL.D.,
Late Statistical Secretary, Inspectorate-General of Chinese Customs.

(*Continued from page* 28.)

Beans were first recorded in 1870 with an export of 578,209 piculs, and beancake in 1890 with 96,297 piculs; the trade in them increased: in 1905—beans 2,665,523 piculs, beancake 2,897,948 piculs; in 1912—beans 10,304,180 piculs, beancake 8,162,989 piculs. *Bristles* were first recorded in 1894 with 18,378 piculs, increased in 1907 to 42,124 piculs. *Cotton* in China is both imported and exported. The import of the first phase was not maintained, but, in 1867, still amounted to 336,072 piculs; in 1905 it was 90,581 piculs, and in 1918 was 190,110 piculs. Exports were 29,391 piculs in 1867, but in 1905 they were 789,273 piculs, and in 1918 rose to 1,292,094 piculs, all to Japan, with a war value of 38 million taels (14½*d*. a lb.). *Firecrackers* were shipped from Canton to America, 16,186 piculs in 1867, and 166,076 piculs in 1907. *Matting*, also from Canton to America, 89,908 rolls of 40 yards in 1867, and 478,851 rolls in 1907. *Fibres* (hemp, jute and ramie) were first recorded in 1879 with 10,456 piculs, and increased to 300,882 piculs in 1905, and 523,923 piculs in 1918; but China's capacity for the production of fibres has scarcely been touched. In 1905 the export amounted to 18,000 tons, and in 1913 to 21,400 tons; from British India, with no larger area or population, the export of hemp and jute in 1905 was 675,000 tons.

Hides were exported in 1867 to the small amount of 146 piculs; in 1918 their export was 425,045 piculs of cow and horse hides, and 9,656,933 pieces of goat and sheep hides undressed. *Skins*, dressed, chiefly of goat, kid and lamb, were valued in 1867 at 5,501 taels and in 1907 at 7,439,821 taels. *Oil seeds* (cotton, rape and sesamum) have only recently entered into the foreign trade; in thirty years the export, in piculs, has been as follows:—

	1888.	1898.	1908.	1918.
Rape . . .	873	212	54,074	670,126
Cotton . . .	..	566,105	191,077	165,303
Sesamum .	3,027	47,388	1,792,435	234,103

The rape and cotton seed went entirely to Japan, and the sesamum, prior to the war, went chiefly to Germany and France. *Expressed oils* were exported, 1,142 in 1867, and 3,651,511 piculs in 1918; of the last figure the oil of the soya bean has furnished nearly two-thirds, with groundnut and wood-oil (from the nut of the Aleurites) coming next. Of *Strawbraid* the export in 1867 was 1,361 piculs, and in 1907 was 103,246 piculs; in 1918 it was only half the latter amount. *Human hair* was first exported after the revolution of 1911-12, causing the abolition of the queue as the badge of Manchu supremacy; in 1913 the export was 24,477 piculs, and in 1918 it was still maintained at 14,382 piculs.

We come now to the consideration of the trade in foreign products imported into China.

Opium.—The value of the import in 1867 was 32 million taels; in 1905 (the last year before the opium reform edict) it was 34 million; and in 1918 it had disappeared from the statistics, except for a quantity of 333 piculs of Persian opium imported from Japan for consumption in the leased territories of Dairen and Kiaochow—under Japanese control. Its decline in importance is shown by the following table of the percentage of opium to all foreign imports:—

Year . .	1818.	1833.	1867.	1905.	1918.
Per cent. .	11	50	46	7½	..

Cotton manufactures were not imported in 1833. In 1867 their value was 21 per cent. of the value of all imports, and in 1905 it was 40 per cent.

Cotton yarn was imported in 1867 to the extent of 33,274 piculs, entirely of English spinning; it was of the finer counts, with an average value of 48 taels (£16) a picul; and its total value was 11 per cent. of all cotton

products. In 1905 the import was 2,577,748 piculs, viz.:—

English	22,075 piculs,	of the finer counts.
Indian	1,867,809 „	Mainly of the coarser counts, 12's to 24's.
Japanese	684,671 „	
Hong Kong	3,693 „	

The average value was 26 taels (£3 18s.) a picul, and the total value was 36 per cent. of all cotton products; in 1903 and 1904 the percentage of yarn had been 52 and 48 respectively. If we add the value of the machine-spun yarn from the factories in Shanghai and other Treaty Ports of China, it may be declared that normally well over half of all foreign cotton products is in the shape of the semi-finished product yarn. It is used to give a strong warp, on which the people in their homes weave a coarse durable fabric, filling in with a hand-spun weft of Chinese cotton; it penetrates to every corner of the country (386,669 piculs in 1906 to Chungking, on the upper Yangtze, 1,400 miles from the salt water), and in every village street may be seen the long white stretches arranged by the women in preparation for the weaving.

Of plain cotton fabrics (shirtings, sheetings, T. cloths, drills, jeans, etc.) the import in 1867 was 3,738,965 pieces, about 119 million square yards, of which about 130,000 pieces came from the United States, and the rest mainly from England; their value was 72 per cent. of all cotton products. In 1905 the import was 28,702,693 pieces, about 1,167 million square yards, and their value was 48 per cent. of all cotton products; their country of origin was as follows:—

	Pieces.	Square yards.
English	14,393,846	589,200,000
American	12,693,793	519,770,000
Japanese	789,290	30,530,000
Indian	651,011	22,330,000
All others	174,753	5,770,000

In 1918 the greater part of the import was of Japanese weaving.

Of fine cotton fabrics the import in 1867 was 781,359 pieces, about 16 million square yards, almost entirely of English weaving; and their value was 17 per cent. of all cotton products. In 1905 the import was 10,821,885 pieces, about 220 million square yards, and their value 15 per cent. of all cottons; of this value 84 per cent. was of English weaving, 7 per cent. of American, and 5 per cent. Japanese. These fine cottons were, in 1905, to the extent of 70 per cent. made up of cotton imitations, cheap substitutes for more expensive woollen fabrics—flannel, blankets, Italians, lastings, Spanish stripes, etc. —for China is a land of cheapness.

Imports other than opium and cotton products were valued in 1867 at 22½ million taels, being 32 per cent. of all foreign imports. In 1905 their value was 237 million taels; but with this tenfold increase in value, the percentage rose to only a little over 50.

Woollens were imported in 1867, with a value of 7½ million taels, being 10 per cent. of all imports; in 1905 the value was 4½ million taels, less than 1 per cent. of all imports. The Chinese in the past have not wanted our woollens; the well-to-do have always preferred their native silks, and the poorer classes have worn winter clothing of wadded cotton, and in the north have warmed themselves with sheepskin coats in their fireless homes. The establishment of the Republic has brought with it the adoption of Western garb by many thousands of the gentry, and that involves an increase in the use of woollens; but the import in 1913 was under 5 million taels (nearly a third yarn), and the value has not in any of the subsequent years of war reached 4 million taels.

Metals in 1867 were 1½ million taels, 2 per cent. of all imports; and in 1906 were 20 million, 5 per cent.; in 1905 the value had been 46 million, over 10 per cent., but that was inflated by an enormous exceptional importation of copper for the mints, which were coining money in a double sense. Iron and steel rose from 7,000 tons in 1867 to 161,500 tons in 1905; and tinplate from 104 tons to 10,400 tons; but to those figures have to be added the large quantities of hoop iron, tin linings, and tin containers, used for baling and casing those commodities which require protection; no record is kept of those quantities, but in China nothing is wasted—nothing thrown away, nothing given away.

Foreign *coal* was imported in 1867 to the amount of 113,439 tons, with practically no Chinese coal brought to the treaty ports; in 1905, about 400,000 tons of Chinese coal were moved from port to port, and 1,314,032 tons of foreign coal were imported, mostly from Japan; the import into Hong Kong was probably not much less. *Cigarettes* were unknown in 1867; in 1905 their value was 4½ million taels, of which a half came from the United States, a fourth from England, a fourth from Japan; in 1913 the value was 12½ million taels, of which more than two-thirds were from England; in 1917 the value was 31½ million taels, a half from the United States, tenth from Canada (probably also from the United States), and a fifth from England. *Aniline dyes* were not recorded in 1867, when

the Chinese still used their native dyes; in 1913 the value was 5½ million taels, in addition to 9½ million taels of synthetic indigo to displace the natural indigo of the country. Nearly all these dyes came from Germany.

The taste for foreign luxuries has been introduced by returned emigrants, and *wheat flour*, with no import in 1867, was imported in 1913 to the extent of 156,000 tons, mostly from the United States, but about 40,000 tons (perhaps American flour) were imported from Japan to Dairen. *Window glass* and *glassware* were valued in 1867 at 25,000 taels, and in 1913 at 2¼ million taels. *Matches* in 1867 figured for 79,236 gross of boxes, valued at one tael (6*s.* 8*d.*) a gross; and in 1913 for 28½ million gross, valued at 0·223 tael (8 pence) a gross, coming 99 per cent. from Japan. On the other hand 2,000 tons of flints were carried from England to China in 1867, and soon after that disappeared from the returns.

Kerosene oil was in 1867 imported, to the extent of 29,842 American gallons,* for the use of the foreign residents only. The trade began to expand in 1878, when the import was 4 million gallons, all from the United States; Russian oil was introduced in 1889, Sumatran in 1894, and Borneo oil in 1901. The import in 1913 was 184 million gallons, of which 61 per cent. were American, 13 per cent. Borneo, 3 per cent. Russian, and 23 per cent. Sumatran.

Of *sugar* the import in 1867 was 11,080 tons, entirely Chinese sugar reimported into China from Hong Kong. In 1913 the import was 423,330 tons, of which about 6,500 tons may have been Chinese sugar reimported; but of the rest, 17 per cent. was sugar refined in Hong Kong from crude sugar originally imported from the Dutch Indies and the Philippines; 20 per cent. was refined in Japan from Formosan sugar; 31 per cent. was crude brown and 28 per cent. was soft white sugar, imported from the Dutch Indies, the Philippines and Formosa, either direct or through Hong Kong.

These are the most important categories in the foreign trade of China; but, before considering the distribution between the different countries I will deal with the Balance of Trade.

In the first phase the trade was balanced only by the constant importation of silver dollars, until, towards its close, a way was found, through opium and cotton, of providing the funds required for buying the tea and silk for which the foreign traders came to China. These means, supplemented by the discovery of Manchester, sufficed to carry the trade through the second phase, except that in the crisis of the Taiping rebellion, through the combined action of the hoarding of silver, and of the large quantities of silk thrown on the market, the foreign traders were driven to resume the importation of silver dollars to avert disaster. In the third phase the tide gradually turned the other way, and, by the opening of the twentieth century, the value of imports constantly exceeded that of exports—by 82 million taels in 1903, by 80 million in 1909, by 167 million in 1913, and even in 1918, in time of war with no importation of opium, by 70 million taels. In 1904 I made some investigation of the visible and invisible assets and liabilities of China in her commercial dealings with foreign countries; and in the following table I give a summary of the results, together with supplementary figures in later years by my successor:—

* Ten American gallons equal 8·34 British imperial gallons.

	1903. Million taels.	1909. Million taels.	1913. Million taels.

* Singapore resembles Hong Kong in being a distributing centre for countries to north and south.
† Tea *via* Kiakhta only.
‡ Singapore resembles Hong Kong in being a collecting centre for countries to north and south.
§ Trade by land frontier not included.

We come now to the distribution of the trade—the countries from which the imports came, and those to which the exports went. Here we are confronted by a difficulty. The Chinese customs have no power to demand declarations or certificates of origin or destination, and cannot go behind the bill of lading or the voluntary declaration of the trader. When German goods pass through Genoa or Antwerp, or American goods through Yokohama, they have to be assigned to Italy, Belgium or Japan respectively. So, too, the products of all the nations, passing through Hong Kong, lose their identity, and must, in the Chinese Customs returns, be assigned to that port. But Hong Kong produces little outside its refining of imported sugar, and its consumption is (was in 1905) that of a population of a third of a million. Commercially it is a collecting and distributing centre for South China in precisely the same degree that Shanghai is for Central China; and in any serious consideration of China's place in world trade, Hong Kong must be treated as part of the Chinese commercial area, regardless of the flag that flies over it.

The simpler trade of 1867, in so far as it was camouflaged by Hong Kong, Antwerp and other distributing ports, I found that I could analyse without difficulty. For 1905 I took the returns of all the countries of the commercial world, and abstracted from them particulars of their trade with China and Hong Kong—their special trade, excluding transit trade. I was thus able to make out the tables on page 37 showing the actual distribution of the trade of China within a small margin of error.

On these tables I will comment very briefly. In the export table the showing of the United Kingdom is bad—the fact cannot be disguised. It is explained by three principal causes. In the first place England no longer buys China tea, but takes it now from her own empire—from India and Ceylon. You cannot eat your cake and still have it; and if you will grow your own tea, if you will develop your own possessions, you must be satisfied with the advantages from that, and cannot at the same time expect to retain your dominating position in the countries which formerly supplied you. In the second place, England has not taken her proper share in developing the new export trade of China: oil seeds go to Japan, France and Germany (I am considering solely pre-war conditions); fibres go mainly to Germany; and so on. This is partly due to lethargy, but principally to the fact that, here also, England draws her supplies from her own possessions—jute from India, palm-kernels from Nigeria, etc.—and it may be that the development of these possessions is a sufficient compensation for the relative loss of the Chinese trade.

For the third principal cause there is no such compensation. Through the whole of my first and second phases, down to 1867, London was the Western world's market for silk; Lyons, Milan and New York silk-weavers went there for their raw material, and the London merchant levied his toll on the transaction. That had to end some day, and the end came with the opening of the Suez Canal; and now Lyons and Milan buy their Chinese silk in Shanghai and Canton.

The import table is more intricate and more interesting. The United Kingdom, in the first phase, could send little beyond a small quantity of woollens; in the second phase, it was discovered that Manchester cottons could be sent with profit to a country which, in the first phase, had sent cotton nankeens to England; and in the third phase this trade in cottons was greatly increased, with almost a monopoly of fine cotton cloths, for which a natural advantage is found in the soft Lancashire air, and supplying a full half of coarse cottons. While the English percentage of the whole import trade fell nearly a half, it was in a much larger trade, and the absolute amount increased four-fold from 1867 to 1905, an increase only partly due to the reduced value of the silver tael.

The percentage of British India fell more than half, but the absolute amount increased three-fold—made up with about 35 per cent. opium and nearly 55 per cent. cotton manufactures; and now (1919) opium has disappeared from the import trade, and India will depend mainly on her cotton yarn and coarse cottons for maintaining her hold on the Chinese trade.

The Russian increase is due to the inclusion of the value of the trade by the land frontier, for which no statistics of earlier years could be obtained.

Germany created a new trade, amounting in 1905 to 25 million taels, one-fifth of that of the United Kingdom; and, apart from synthethic dyes, her trade was maintained by two factors: her traders pushed into the market, hunted up buyers, gave them articles in the shape in which the buyers wanted them, and devoted themselves night and day to their work; her manufacturers turned out a cheap form of product ("billig und schlecht") adapted for a land of great poverty and great thrift. And German

did not eat German; they competed with the English and the Americans, but they combined their own conflicting interests.

Belgium also created a new trade, but it must be borne in mind that the Belgian mills are frequently the free-trade face of financiers of protectionist France—who supply their home trade from French mills, and their foreign trade from Belgian mills.

American trade shows a great development, due to three main causes. First, the creation of the demand for kerosene oil, and in the future for petrol. Secondly, the discovery of the fact that a country growing its own cotton can supply coarse cottons on better terms than one which must import its raw material, with the result that in 1905 the United States supplied 45 per cent. of the Chinese demand for such cottons. Thirdly, American business methods, which have been copied in many respects by the Germans, notably a very considerable elimination of the middleman.

Japanese trade had taken a stride forward in 1905; in 1913 its share in the export trade was close on 20 per cent., and in the import trade close on 25 per cent.; and in 1918, under war conditions, it had over a third of the export trade, and not far from half of the import trade. (The intervention of Hong Kong prevents a more accurate estimate.) This result was natural, in the case of a country contiguous to China, and one entering on a course of industrial development. Japan imports Chinese and Indian cotton and sends back to China her cotton yarn and coarse cotton cloth; and she makes the thousand little articles required in daily life cheaply and in a shape adapted to the Asiatic taste. In addition to her natural advantages, she sends her thousands of chapmen travelling through China, living as the Chinese live, speaking their language, and subsisting on the meagre profits of a peddling trade; and, even after peace conditions are restored, the Japanese will be formidable competitors in all the minor branches of trade, and they will be the more formidable because they will be supported by the political power of their government in all their purely commercial operations, and these will be in a country which demands cheapness before quality.

What you are really yearning to have me tell you is—what adverse conditions have been created by the war, and what must be done to re-establish the strong position which England has always held in the Chinese trade. I may point out that Japan, an adjacent country, whose industries have not been dislocated by the war, and which requires less tonnage to carry her products to the Chinese market, has acquired a very strong position, from which it will be difficult to dislodge her; much time must elapse before the English mills can furnish the supplies demanded, and the necessary tonnage be available; and much strenuous effort will be required to reconquer lost, and re-establish imperilled, markets. Beyond that it is not my business to give you directions for the future. That is the task of the business man—the Manchester man for the Manchester trade, the Sheffield man for the Sheffield trade—and just in the degree that the business man will share with his colleagues and rivals his knowledge and his reading of the situation, to that degree will he contribute to the extension of the market for English goods, and of his own market. Close corporations, exclusive dealings, trade secrets for one's own sole benefit, are things of the past; co-operation, amalgamation, alliance, are the watchwords of the future.

I will, however, suggest some needs of the future which occur to me, in the hope that they may be worked out by others.

Commercial Information. — The British Government receives reports from its consular agents—I have read many, and I much admire them. They are written annually, pass on their leisurely course through the Foreign Office and the Board of Trade, are printed, and, if you happen to hear of them and order copies of an individual report, you will have the satisfaction of reading in 1919 what were the conditions of trade in a given district in 1917. The American Government receives and publishes similar reports; but if a consul is seized with the idea of writing a note on a particular article or branch of trade, he sends it, the Government publishes it without the loss of a day, the mailing office addresses it by machinery according to a list of applicants for anything relating to that subject, and, when it is read, the news is fresh. It may be a half-page note on the size of egg-cups for Asiatic eggs, or a ten-page note on an experiment in smelting iron; it may give details of a new lode of nickel ore; it may refer to some change in banking practice; but, whatever it is, it is written without rhetoric for the information of the business world.

Commercial Attachés.—An idea is prevalent that men with business training should be selected for such a post. That is an error. The commercial attaché must be first of all a

diplomatist: he must ferret out the business secrets of the country he is working in, and the business secrets of his rivals in that country, much as the military attaché has to ferret out military secrets. A man who has qualified in the severe test of the Civil Service examinations, has then undergone the varied and broadening training of the China Consular service, and has then been selected by his superiors to be commercial attaché, is more likely to acquire the requisite knowledge of business methods and requirements, than a man with a solely business training is to acquire the other qualities needed. The China Consular service is a special service, requiring special training owing to the difficult language and to the complicated duties arising from the privilege of extra-territoriality enjoyed by all Europeans. I have known several commercial attachés and formed a respect for their work, and there is one suggestion I may make: every commercial attaché in China (I refer here only to China) should be a triplet; in each year one of him should spend his time in the great treaty ports, including Hong Kong, studying primarily the questions affecting the import and export of commodities; one of him should be travelling continually through the interior studying the producing and consuming markets; one of him should be in England, in European countries, and in the United States, studying the production and sale of goods for the Chinese markets and the utilisation of Chinese produce, and in England giving addresses and holding conferences at industrial centres. In the second and third years each should move on to the next function. You may object that this will be expensive. You cannot make an omelette without breaking eggs; and if knowledge is worth having it is worth paying for.

One obstacle to your trade in general with your consuming markets, lies in your system (or no-system) of weights and measures, and your currency even is a difficulty in quoting prices. The metric weights and measures are universal except in the United States, China and Japan; and everywhere, except in the United States, currency, weights and measures are all based on a decimal notation (except that in China there are 16 ounces to the pound weight as in England). I only mention this subject, and suggest nothing in the way of a remedy—for England is very conservative.

Education.—Take the Chinese and educate them. You have in China a people naturally inclined to you. They have fought you as every other nation has, but they have the most friendly feeling to you; and you have only to encourage that feeling, not to create it. To-day, for the higher education, for university instruction and assimilation of thought, thousands of students go every year to Japan, because of propinquity in distance and in thought; hundreds every year to the United States, because they always have gone there and because special inducements are offered; some dozens come to England, attracted here by affinity, notwithstanding that there is nothing to invite them; and a few individuals used to go to France and Germany. Any expenditure to induce students to come to England will be amply repaid; to put it on the lowest basis, a mining engineer trained in England will be acquainted only with English engineers, methods and machinery—and orders will follow; a student in International Law educated in England will be more likely to take the British view of freedom of the seas.

Production.—I need not tell this audience that a country or a producer offering an article at twenty shillings will always lose his market to a competitor offering the same article of the same quality at nineteen shillings. In the past, with cheap coal, and cheap raw material, England has always maintained her foreign markets—what she has lost in one she has made up in another. Here is your chief danger in China. I do not fear high wages. High wages mean low labour cost—always on the supposition that, as in the United States, high wages give increased productivity. What I do fear is increased cost of raw material. In the past England was a creditor nation, drawing in her raw material from all the corners of the world on the most favourable terms, because the payment of the debts due to her created always rates of exchange in her favour, and because the outward cargoes of coal supplied tonnage to bring back return cargoes at low rates of freight. The creditor position has not been entirely destroyed, but it has been greatly weakened, and your raw materials will cost you more in the future. This creates a problem which will tax to their utmost the abilities of your economists—and it is one to be solved by them and not by the man in the street.

Advertising.—Find out the right way of advertising your wares to China. Here you draw a cheque in favour of an advertising agency, and he informs a credulous public that A's soap will wash everything except a conscience, or

that B's mixture is worth a guinea a bottle except for paying a bill. In China find out what kind of advertising is worth spending money on. Trade museums are good, if they are kept up-to-date; but travellers with samples are better, and one traveller might represent a dozen non-competing firms. Be liberal with samples. Mankind loves a free sample; I have had them thrust upon me—by representatives of American and German makers—and they brought orders. The Japanese system of packmen peddling through the country is one which it is not in your power to imitate.

Middlemen.—Whatever you may do with middlemen in other regions and in other respects, you cannot do without the middleman in China—the old-established firm, knowing the Chinese merchants and their ways, their solvency, and their requirements. Keep him going but supplement him, and stir him up to be modern. And be modern yourselves.

On this key I close—be up to date. Find out a good method for holding the China trade, and when found, make a note of it.

DISCUSSION.

The Chairman (Mr. Byron Brenan) said that all those who had listened to the paper must feel that they had a very clear vision of the history of the last three hundred years of trade in fragrant tea, clinging silk, soothing opium and aromatic spices, gradually changing into the more prosaic trade of to-day with such items as leather, soaps, salted fish and guano. The author had, with great dexterity, foreshortened for them the history of trade in the last three hundred years, and had then gently brought his listeners up to the present time, when daydreams had to be abandoned and stern realities faced. He had drawn a curve which connected the past with the present, and he left it to the practical man to project that curve, after making due allowance for disturbing factors, so as to enable him to foretell the future. If it was only possible to know what those disturbing factors were going to be it would be an easy matter. In the old days what could have been more simple, for example, than to load a ship with merchandise and silver dollars, cast anchor in the harbour of Canton, and gradually proceed to change the imported cargo into one of tea and silk for the return journey? But that was no longer possible. It may have been then extremely profitable for a few favoured ones, but now it was necessary to think of England with a much larger population and ever-increasing factories. After accompanying Dr. Morse through the three phases he had depicted so clearly, it was necessary to consider how Great Britain stood to-day *vis-à-vis* with China, when she had just emerged from a four years' war and was very eager to resume her commercial activity, and China was still engaged in a half-hearted civil war, but as keen as ever on business and very anxious to take advantage of everything with which nature had provided her. He proposed to say what, in his view, were the prospects of the future. Speaking in a very general way, the commercial relations of Great Britain with China now might be divided into three—first, the general exchange of ordinary articles of merchandise; secondly, providing China with modern methods for developing her industries and enabling her to undertake new ones; and, thirdly, that kind of work which was not usually undertaken by private individuals but more usually by the State, such as dockyards, arsenals, river conservancies, and big things of that kind. With regard to the first division, the modern merchant was not content to proceed upon the lines adopted by the old-fashioned merchants. In the not very far-distant years, the British merchant was quite content to stay in his counting-house and await the arrival of a customer. The more enterprising man now went forth himself and tried to find new customers and introduce new articles, and to look for produce which so far had not found a market in Europe. There were new fields for activities being opened up every day as railways and other means of communication were developed. It was inevitable, of course, that the Chinese by degrees should provide themselves with articles which, so far, Europe had supplied them with, because they had the raw material at hand and abundance of skilful craftsmen and cheap labour; but he thought it was not a matter for regret to see such changes, because it merely meant a diversion of money into other fields where Great Britain would have a fair chance of getting her share. He regarded with satisfaction any change which tended to enrich China. It was possible that certain individuals would lose, but that they must take as philosophically as possible because, on the whole, a rich China was so much to the good of this country; China could not become a prosperous country without Great Britain indirectly sharing in that prosperity. His second point had to do with trade in mechanical appliances which would enable China to improve her present industries or develop new ones. The trade in machinery was still quite in its infancy. The Chinese were perfectly willing to adopt new methods, and would take up anything if they were convinced it would be profitable and practicable. Between the originating of a new idea and its completion there was a certain period of time during which money had to be spent, and that was the difficult moment for the Chinese. He would leave it to the great manufacturers and financiers of this country to help China to tide over that period. There was a great field for electrical appliances and for machinery of every kind. His third division was one which would scarcely attract the individual firm or the single merchant; it contained matters that were undertaken by the State, and it implied a great deal of spade work,

expenditure of money, and patience. It was a field of operation with great possibilities; the reward was great, and it was worthy of serious consideration. Whenever a matter of great importance occurred, such for example as the security of the seas or the preventing of enemies landing on our shores, it was not left to each individual to take such steps as he thought best to meet the difficulty; the Government had considered all that and taken their own measures. Also, if a city with a large population found itself running short of water, it was not left to each person to take a can and get his supply, but the corporation, acting on behalf of the city, provided funds, found the source of the water and laid down the pipes. In view of the immense opportunities which were now being presented in China, why should not their great manufacturers, engineers and financiers all join hands, sinking their rivalry and competition, and work together towards one common object? It was not only that they would make money while they were doing so, but they would be preparing a wealthy and prosperous China, which would be a huge factor in future international trade. He thought the Federation of British Industries might take a few more steps upon the road leading to the promised land, a land which would most certainly be staked out by others if Great Britain let the opportunity go by.

Sir Charles Addis wished to acknowledge publicly the great debt due by the whole of the commercial community dealing with China to the author for the work he had done. This work would endure, and he had paid a compliment to all the Fellows of the Society in delivering his paper that evening. His narrative of the origin and development of Chinese foreign trade was curiously interesting and curiously disappointing. After half a century of free and open foreign intercourse it was really surprising that a people, sober, industrious, and intelligent, should care so little for the good and useful things which Great Britain was able to offer them, and that the expenditure of each unit of the population amounted to only a few shillings a year. No one could set foot in China without being struck with the extraordinary agricultural, commercial and industrial activity of the people. The waterways, the mountain paths, and every part of the country teemed with people making things for each other and exchanging them with each other; they were born merchants. The first and most obvious explanation of the slow progress of commerce with China was the Chinese self-sufficiency; the diversity of climate and the variety of production gave an importance to the internal trade which placed it beyond all competition with any foreign trade that China was likely to reach in the next century. There had been progress of a kind, and in spite of herself China was likely to be drawn more and more into intercourse with the West and into the exchanging of her products with the West. One of the great obstacles to foreign trade in China had been the enormous importance attached by the Chinese to agriculture. Even the modern educated Chinaman distrusted industrialism as he had seen it in his visits to Europe, and relished very little the idea that one of the concomitants of foreign trade, which was a tendency to stimulate industry in the country, should develop in China. It had been said continually that China was on the eve of very great developments, but those developments did not seem to mature. He would advise those who were engaged in trade with China to go step by step and to be a little cautious about hurrying the pace too much or encouraging any enterprise of which they had not well sounded the foundations. No doubt the merchant and the banker would be the better for being better informed. It was possible that some of the schemes for consulates or for commercial attachés might bear fruit, but he did not think there was any substitute for individual study, enterprise and initiative. Those were virtues which in a period of reconstruction might be overlooked. It might be that the modern merchant had been led to place his trust in outside things and not in the virtues which in the past had been so valuable to this country.

Sir Richard Dane, K.C.I.E., said the author had referred to the currency of China, and had said that the unit was a tael, or Chinese ounce of silver. That, however, was only true now to a very limited extent. When he went to China in 1913, to assist in reorganising the Salt Revenue Department, he found the Chinese were trying to publish such accounts as they published in dollars. The bankers assured him that the tael was the only thing that could possibly be recognised, and the Financial Secretary who came to the Salt Revenue Department from the Maritime Customs Department was also at first in favour of recognising only the tael. But inquiries went to show that, except in the North-Western provinces and in the Treaty Ports, where the banks recognised the tael, in nearly all business transactions where money was actually passed, the account was worked out from taels into dollars, and payment took place in dollars. Working on that basis, the Administration introduced a system by which the salt revenue was received in dollars, and any loss which was incurred in getting the money to Shanghai was written off as a loss in exchange. In Szechuan the Provincial Government minted dollars after the revolution 10 per cent. less in intrinsic value than the old dollars, and he found that in the province those dollars had exactly the same value as the old dollars and were exchanged for the same number of coppers, and produced also practically the same amount of taels in Shanghai. It showed that the Chinese people were very anxious indeed to have a dollar currency introduced. At the end of 1915 things seemed to be moving so fast that he sounded the foreign banks to see whether they would be prepared to accept a Chinese dollar as a dollar in every Treaty Port in

China without working out its value in taels; and he told them that if they could do it, he thought he could secure from the President the appointment of foreign Assay Masters who would guarantee that the dollar had the actual value it purported to represent; but there were difficulties, and the matter went no further. At present, owing to the disordered state of the country, any scheme of that sort had become impracticable. He thought the future of British trade lay in the co-operation of the British with the Chinese, and he believed the most effectual way of securing the co-operation of the Chinese was to teach them the English language. They were eager to learn it, and they learned it with great facility; and a Chinese who knew English was more likely to be on friendly terms with the English-speaking people than one who did not.

PROFESSOR C. A. MIDDLETON-SMITH said that for the last seven years he had been in the University of Hong Kong attempting to train young Chinese in applied science work, and every year he had been brought into contact with those Chinese his admiration and respect for them had increased. Yet, much as he liked them as individuals, he had found himself every year a little less confident in the future of those young men if they were left to themselves. The one thing that would have to happen in China was co-operation between the Chinese and the Anglo-Saxons. The Chinese took very kindly to machinery; the Cantonese was simply a born engineer, his mechanical ingenuity being equal to that of any mechanic he had seen in this country. He was convinced that China was about to change very much because of the applied science work that had been done. During the last five years there had been a change in the large industrial centres of Great Britain, and a remarkable revolution in workshop production; the workshops were full, and at present unable to take orders. But at some time or other they were bound to need orders from abroad, and just as they reconstructed themselves during the war to meet the menace of war, so he was sure their methods of trade would be so reconstructed as to embrace Asia, and especially China. Many of the great leaders of industry were making active preparations to go to the Far East, and the concerns those leaders represented were concerns with capital running into millions sterling. They had men going out to China now investigating the whole thing, and he was sure they would find a big market for their machinery there. There had been a change in China, too. In the old days the Chinese spent a great deal of money on crackers. They had now taken to electric light, and divided their surplus between crackers and electric light. In Shanghai the electric supply station would rank with those of cities such as Liverpool, and at the present time Shanghai was putting in one contract of 18,000 kw. The villages and towns were also demanding electric light. In the past the trade with China had been in tea and opium, and he was convinced that in a few years the trade would be in machinery, and would be enormously more important than it was at the present time. His whole desire was to train the Chinese to develop the resources of their own country, in which nature had been wonderfully kind to them, although they were astonishingly ignorant of them. But they had tremendous mineral and natural resources which could be utilised in connection with scientific work, and he might mention that during the war China sent large quantities of tungsten to this country. The Chinese were as idealistic as other people, and they wished to create a better China and to develop the natural resources of their country and raise the scale of living; and in doing that he believed they were in their small way helping not only China but the whole world.

MR. F. ANDERSON said that everyone connected with China was under a deep debt of gratitude to Mr. Morse, not only for his paper, but for all he had written on the subject of China in the past. One outstanding feature that had struck him in his experience of China was that foreign intercourse had been carried on with the goodwill of the Chinese people, but almost always with the continued opposition of the Government; and all the development that had taken place in Great Britain's foreign trade with China had been accomplished in the face of official opposition. Whether that official opposition would come to an end under the republic, or whatever form of Government was eventually adopted in China, remained to be seen; but at the present time he thought the people of China as a whole were exceedingly anxious to develop industries in a great many different forms. The fact that China generally was an agricultural country, and that the population was constantly increasing, meant that the struggle for existence as an agricultural country would be so great that it would eventually lead to internal complications if nothing was done to increase the opportunities of the population for employment other than agriculture. In that industrial development there would be very great and very rapid changes in China, if only the incubus of official interference could be overcome. There was no country in the whole world that had more coal than China, yet that coal had been kept under the ground for centuries, and was at the present moment very largely undeveloped—and the same applied to iron—not because the Chinese did not want to develop it, but because of the official interference with the private individual and the tendency of the officials to try to get as much as they could out of any new enterprise. The East, in that respect, might be a warning to Great Britain, because, as was well known, there was a tendency for the British Government to interfere more and more in trade. No interference by the State would ever be a satisfactory substitute for the initiative

of the private individual. Great Britain's position in China had been built up, not by officials, but by the British merchants, and he believed that the future success of Great Britain in China mainly depended upon her merchants. He had considered more than once whether advantage could not be taken of the present disturbance in currency matters to endeavour to come to some international agreement which would stabilise the metallic basis of the currency of the whole world. Silver was at an extraordinary rate now, and there was an extraordinary premium on gold, but it was a curious thing that the premium on gold was very little different from the premium on silver if we took 60*d*. per ounce—the old international standard price—as the par value of silver, the premium on both was roughly 25 per cent.—that was to say, the original parity of gold and silver was maintained to-day. If there was great industrial expansion in the East and the previous state of things was allowed to recur, if the tael went down to 2*s*. 4*d*. and the dollar to 1*s*. 7*d*., with Eastern wages paid at the depreciated ratio of pre-war days, China would be a far more serious competitor in the industrial production of the West than she would if the artificial advantage of depreciated exchange was not given, and if silver were re-established in its former position in international currency.

Mr. S. Barton said that without Dr. Morse's work British officials in China would be under a great handicap in doing their work, for he did not think anybody was capable of doing work properly in China, where a knowledge of the past was essential in order to understand the present, without a careful study of Dr. Morse's book. With regard to trade in China, the conditions were not what they were even six years ago, and it was impossible to form a correct estimate of the various panaceas which were being offered now for the improvement of trade in China without a knowledge of what China was to-day. Sir Richard Dane advocated teaching the Chinese English, and he was sure that everybody who had to deal with foreign-educated Chinese would agree that the Chinese student should be taught in China. The complement of teaching the Chinese English was to teach the Englishman Chinese, because the language was essential in organising trade in China. Firms who were going to send men out to China should see that they not only studied the language in China, but commenced to learn the language before they left this country. There were schools for British merchants in the principal Treaty Ports, and there was an institution in London which afforded opportunities for studying the language in this country.

Mr. Cecil A. V. Bowra thought the main reason why trade with China grew slowly was the political disorder of that country. There was no peace in China. The provinces were all more or less independent. Trade routes were interrupted, and the railroads were harried by troops. For any great growth in China a strong Government was needed, and order, and those things seemed to be as far away now as they were sixty years ago. It might, of course, be possible that the Chinese would bring about a better state of things themselves, but it might possibly be done by the League of Nations.

On the motion of the Chairman, a hearty vote of thanks was tendered to Mr. Morse for his paper.

The meeting then terminted.

SPANISH SWEET PEPPERS.

Spanish sweet peppers, or pimientos morrohos as they are known locally, are produced principally in the Provinces of Logrono, Lerida and Valencia. The principal canning factories are at Calahorra, in the Province of Logrono; Lerida, in the Province of the same name; and the port of Valencia, which is in the famous fruit belt of Spain. The highest grade peppers come from Valencia.

In recent years, writes the United States Consul at Barcelona, the peppers of Logrono have lost much of their sweet quality, largely owing to cross pollinisation with the ordinary strong variety grown in the near vicinity. Although the growers of this district have made, and are making, efforts to bring their product back to its former quality they have as yet been unable to do so.

The acreage planted in sweet peppers during the 1918 season was from one-third to one-half the usual amount. This was due to a variety of causes, the most important one being that lands which have heretofore been planted in sweet peppers are well adapted to the cultivation of sugar-beets. Since the price of sugar in Spain, as in all other European countries, has been so much higher during the war than in normal times, it is but natural that the growers should have turned to the cultivation of a crop which has a wider market and a higher price. Another reason is that the demand from the usual markets of both North and South America has been much less because of the higher cost of the delivered product in those places. This increased cost has been brought about by the unusual price of tin plate for cans and by increased ocean freight rates.

In addition to greatly reduced acreage, several other factors tended to curtail last year's crop, one being that the proper cultivation of the plants ordinarily demands a generous use of fertiliser, but for some years past very little has been used owing to its greatly increased cost and general scarcity.

Sweet peppers are picked and canned during the months of September, October and November. The harvest begins in the more southerly Province of Valencia and gradually proceeds northward as the season advances. The product is put up in tins of 280 grammes (9·88 ounces) and 550 grammes (19·4 ounces). The larger tins are packed 50 to the case and the smaller ones 100 to the case, so that a

case contains approximately the same amount, whether packed with small or large tins.

The production of canned sweet peppers last season was as follows: Valencia, 30,000 cases; Lerida, 30,000 cases; Calahorra, 25,000 cases. The production at other places brought the total to 100,000 cases. Shipment takes place from the ports of Barcelona and Valencia.

IRON ORE DEPOSITS IN CELEBES.

The discovery of very large iron-fields in the Middle Celebes, in what is known as the lake district, has created a stir in mining circles in Netherlands Indies, reports from Government investigators having confirmed the original reports.

According to a report by the United States Consul at Batavia, an exhaustive study has been made of the Larona district, which is situated near the outflow of the Towoeti Lake, at a height of about 980 ft. above sea-level, and at a distance of 12 to 18 miles from a point on the coast from which shipment may be made. The Larona field occupies a surface of approximately 2¾ square miles; the other fields in this district are either less important or less favourably situated for exploitation. Further investigation is to be made by the Government of iron-ore fields in other parts of the archipelago.

It is claimed that the Larona ore is similar to that of Cuba and the Philippines; with the exception of the chemical composition the physical properties of these ore beds are equal to the Cuban. The Larona is said to yield common iron ore, chrome iron, nickel, and manganese ore. The average standard of the ore is 49 or 50 per cent. metallic iron.

It is known that the quantity of iron ore in the Larona field is at least 5,000,000 tons of surface ore, and 155,000,000 tons of clay ore, a total of 160,000,000 tons; but the estimate may reach 7,000,000 tons of surface ore and 206,000,000 tons of clay ore, a total of 213,000,000 tons. The ore can be extracted easily and cheaply; the fields cover a large territory, but the ore does not run very deep, the layers extending not more than 39 to 46 ft. in depth.

Considerable study has been made by the Dutch engineers as to the working of these fields. It appears that two methods are open—the smelting of the ore by the carbonisation of coal, the coals of Ombilin and Lematan being quite well adapted for carbonisation, or by electrical smelting. The latter method is preferred, as it is believed that there is sufficient water-power in the neighbourhood of the ore beds, and the establishing of electrical machinery for the purpose can be done at a low cost. An examination of the water-power possibilities is being carried out. The reduction expedient, wood coal, which is necessary for electrical smelting, can be obtained in abundance near the ore-fields.

The question as to the part the Government will take in the exploitation of these iron deposits will be settled later, when all the facts are known, but it will no doubt retain certain rights, whether the fields are worked entirely by a private concern or in part by the Government.

NOTES ON BOOKS.

THE PHYSICAL CHEMISTRY OF THE PROTEINS. By T. Brailsford Robertson. New York and London (1918): Longman, Green & Co. 25s. net.

This handbook of 484 pages, written by one who has long been known as a leading investigator in biochemistry, arrives as a welcome addition to the chemist's books of reference, and, quite apart from this quiescent function, Dr. Robertson's volume may serve to infuse new thought and directive force into the minds of those laboratory workers who have too much settled down and established themselves in the notion that chemical definiteness is mainly to be conceded to such bodies as are crystalline, or have constant boiling point or fusion point.

A note in full consonance with the general tone of the work is prominently placed opposie the title-page—the reminder of Professor J. J. Thomson that "a theory of matter is rather a policy than a creed; its object is to connect or co-ordinate apparently diverse phenomena, and above all to suggest, stimulate and direct experiment." Here we have the soul or essence of Bacon's doctrine that an erroneous theory is far more conducive to truth than an empty or chaotic state of mind. During investigation the policy (or theory) changes frequently, and in this drift of policy we have the best progress.

Despite the fact that there are many colloids other than proteins, Dr. Robertson's volume is largely — by overlap — a treatise on some of the leading characteristics of colloids in general; more especially in certain broad aspects, such as molecular weight, catenary configuration of the molecule, multiple bacisity and acidity, also instability in aqueous solution. Turning to page 342, where opalescence and the Tyndall effect are considered, the opalescence of many colloid solutions is tentatively correlated to the grossness of the molecules themselves, but the author urges that this appears unlikely to be the case in solutions of proteins, there being good ground for believing that the smallest particlps capable of scattering light should have a diameter of from 5 to 10 $\mu\mu$. A study of casein, taken as an example, indicates that in solutions containing 10^{-5} equivalents of base per gramme of the protein, the molecular weight is about 17,600, which suggests approximately the empirical formula—

$$C_{777}\ H_{1241}\ N_{197}\ O_{250}\ S_4\ P_4.$$

A study on this basis suggests that a casein molecule must have a diameter of about $2{\cdot}4\ \mu\mu$, or approximately half the diameter of the smallest particle which can scatter light.

Among the interesting methods for distinguishing the various proteins is the determination of a "gold number" (p. 349). Sodium chloride precipitates colloidal gold, a reaction which is inhibited in varying degrees by the different proteids. On this may be based a volumetric method for distinguishing proteids, and a method applicable to the differential diagnosis of syphilitic sequelae in the cerebro-spinal fluid.

A long review would be largely a summary, and no short review can give a notion of the interest and importance of Dr. Robertson's "Physical Chemistry of the Proteins."

GENERAL NOTES.

Secondary Industries in New Zealand.—The *Board of Trade Journal* (November 20th) reviews the conclusions arrived at by a special committee, after touring the Dominion to ascertain the immediate possibilities of New Zealand's secondary industries. The Committee propose the establishment of a Board of Industries and Commerce and a Board of Science and Industry. The former, consisting of three members of wide business experience, would be empowered *inter alia* to engage in trade, investigate and control prices, prevent exploitation of the public and suppress profiteering, make advances to industrial and commercial concerns, and prevent unfair methods of competition. The Board would also be charged with the duty of investigating such matters as the encouragement, improvement, and extension of New Zealand industries and manufactures; markets outside the Dominion and the opening up of external trade generally; wages and social and industrial conditions; labour, employment, and unemployment. One of the chief functions of the other Board would be the consideration of all proposals for specific scientific researches. It would be able to create scholarships and to award bonuses and prizes "with the object of encouraging scientific and industrial research." Apparently New Zealand is the only Oversea dominion in which an organisation for research has not been provided since August, 1914.

Post-war Steamship Services.—Most of the principal steamship lines which ran services before the war from London, Liverpool, Glasgow, and other United Kingdom ports, to India and Ceylon, are well on the way to complete resumption. The extension of Australian, Canadian, and South African services to Indian and adjacent ports promises to be a feature of the early future. Competition for the Indian carrying trade will probably be keen when conditions have become more settled. Japanese shipowners seem to be alive to the possibilities of the future, and several steamer lines of that nationality serve Colombo and South Indian and, to an increasing extent, other ports of the Dependency as well, on their way to or from more distant destinations. American activities, of which so much has been heard of late, appear to be confined for the present to a few lines mainly from New York and the Atlantic ports. Among European Continental services to India, which are in course of revival, may be mentioned the French sailings from Marseilles *viâ* Suez, Swedish and Norwegian from various Scandinavian ports, and Spanish and Italian services.—*Board of Trade Journal.*

Fabric Construction and Design.—In memory of his son, Lieut. Harry Dent Crompton, fallen in the war, Mr. John Crompton, a member of the Council of the Textile Institute, has given a sum of £2,000, the annual revenue from the investment of which is to be devoted to the provision of awards to the designers and weavers of original cotton textile fabrics, designed and woven by themselves in technical colleges or weaving schools in the British Empire. One half of the fabrics sent in for competition must be manufactured entirely of cotton, but, at the option of the competitor, part or all of the remaining specimens may contain only 70 per cent. of cotton threads and 30 per cent. of threads of any other fibre. Any subject of the British Empire, irrespective of sex, who is a *bonâ fide* student at a technical school, college, or weaving school, shall be eligible to compete for the prizes, unless he or she has left the apprenticeship stage and become engaged in the profession of a designer for textiles; but any candidate to whom a prize of £20 or upwards has been awarded, will not be eligible to compete in any subsequent year. The prizes offered will be one of £25, £20, and £15 respectively, and five prizes of £5 each.

A New High-speed Steel. — The *Iron Age* mentions that chrobaltic alloy, a new high-speed steel, is being used as a substitute for tungsten and vanadium steel by a Chicago company in making milling cutters and other tools with multiple cutting edges. The castings are said to be non-rusting and acid-resisting. The steel may be hardened in oil or air, and the processes of annealing and re-hardening may be repeated without the steel losing any of its properties.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday afternoons, at 4.30 p.m.:—

December 10.—Sir Oliver Lodge, D.Sc., Sc.D., LL.D., F.R.S., "Some Possible Sources of Energy." (Trueman Wood Lecture.) The Hon. Sir Charles Algernon Parsons, K.C.B., LL.D., D.Sc., F.R.S., will preside.

December 17. — Constantine Grunwald, late Chief of Intelligence Department, Russian Ministry of Trade and Industry, "The Present Economic Position of Russia, and some Aspects of its Future Development."

COLONIAL SECTION.

Tuesday afternoon, at 4.30 p.m. :—

DECEMBER 9.—SIR EDWARD DAVSON, President of the Associated West Indian Chambers of Commerce, "Problems of the West Indies." LIEUT.-COLONEL L. S. AMERY, M.P., Under-Secretary of State for the Colonies, will preside.

INDIAN SECTION.

At 4.30 p.m.

THURSDAY, DECEMBER 18.—P. J. HARTOG, C.I.E., M.A., Member of the Calcutta University Commission, 1917–1919, "Some Problems of Indian Education." The Right Hon. LORD MESTON, K.C.S.I., LL.D., will preside.

FRIDAY, JANUARY 2.—A. P. MORRIS, B.Sc., A.M.Inst.C.E., Provincial Art Officer, Burma, "Burmese Village Industries: their Present State and Possible Development."

Papers to be read after Christmas :—

AIR-COMMODORE EDWARD MAITLAND, C.M.G., D.S.O., "The Commercial Future of Airships."

SIDNEY PRESTON, C.I.E., "English Canals and Inland Waterways."

BRIGADIER-GENERAL SIR HENRY P. MAYBURY, K.C.M.G., C.B., M.Inst.C.E., "Road Transport."

CHARLES H. SHERRILL, "Stained Glass."

ALFRED E. HAYES, General Secretary, English Language Union, "The English Language and International Trade."

JAMES CURRIE, C.M.G., Ministry of Labour (Training Department), late Principal, Gordon Memorial College, Khartoum, "Industrial Training."

LADY INGLEFIELD, President, Buckinghamshire Lace Association (North Bucks and Bedfordshire), "The Hand-made Lace Industry."

WILLIAM JAMES GARNETT, First Secretary, H.B.M. Diplomatic Service, "Mongolia and Chinese Turkestan."

GRAILY HEWITT, "Rolls of Honour."

ALFRED H. POWELL, "Ancient Cottages and Modern Requirements." The Right Hon. EARL FERRERS will preside.

CHARLES CROWTHER, "The Arts and Crafts of Japan" (with examples from the author's private collection).

SIR CECIL HERTSLET, late H.M.B. Consul-General for Belgium, "The Ruin and Restoration of Belgium." EMILE CAMMAERTS will preside.

WILLIAM CRAMP, D.Sc., M.I.E.E., "Pneumatic Convoying Plants, with special reference to the Transport of Grain."

L. GASTER, "Industrial Lighting in its relation to Efficiency."

H. M. THORNTON, "Gas in relation to Industry and Housing."

SIR FRANCIS WATTS, K.C.M.G., D.Sc., Imperial Commissioner of Agriculture for the West Indies, "Tropical Departments of Agriculture, with special reference to the West Indies." LIEUT.-COLONEL SIR DAVID PRAIN, C.M.G., C.I.E., LL.D., F.R.S., Director of the Royal Botanic Gardens, Kew, will preside.

INDIAN SECTION.

At 4.30 p.m.

January 2, February 19, March 18, April 15, May 20.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 p.m. :—

February 3, March 2, May 4.

CANTOR LECTURES.

Monday evenings, at 8 p.m. :—

JOHN THEODORE HEWITT, M.A., D.Sc., Ph.D., F.R.S., Emeritus Professor of Chemistry, East London College, "Synthetic Drugs." Three Lectures.

Syllabus.

LECTURE II.—DECEMBER 8.—Phenol, salicylic acid and related substances — Derivatives of aromatic amines and aminophenols, *e.g.* phenacetin —Compounds of heterocyclic structure, antipyrine, flavine, etc.

LECTURE III. — DECEMBER 15. — Modified alkaloids, *e.g.* heroin, euquinine—Organic compounds of arsenic (atoxyl, salvarsan), antimony, mercury and other metals—Conclusion.

CAPTAIN H. HAMSHAW THOMAS, M.B.E., M.A., F.G.S., Fellow of Downing College, Cambridge, and formerly of the Royal Air Force, "Aircraft Photography in War and Peace." Three Lectures.

January 19, 26, February 2.

CHARLES FREDERICK CROSS, B.Sc., F.R.S., F.C.S., "Recent Research in Cellulose Industry." Three Lectures.

February 16, 23, March 1.

WALTER ROSENHAIN, B.A., D.Sc., F.R.S., Superintendent, Department of Metallurgy and Metallurgical Chemistry, National Physical Laboratory, "Aluminium and its Alloys." Three Lectures.

April 12, 19, 26.

ARTHUR THOMAS BOLTON, F.R.I.B.A., F.S.A., Curator, Soane Museum, "The Decoration and Architecture of Robert Adam and Sir John Soane, 1758–1837." Three Lectures.

May 3, 10, 17.

JUVENILE LECTURES.

Wednesday afternoons, at 3 p.m.:—

LOUGHNAN PENDRED, M.I.Mech.E., Editor of *The Engineer*, "Railways and Engines."

January 7, 14.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, DECEMBER 8...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Professor J. T. Hewitt, "Synthetic Drugs." (Lecture II.)

Victoria Institute, Central Buildings, Westminster, S.W., 4.30 p.m. Mr. A. W. Sutton, "The Ruined Cities of Palestine, East and West of the Jordan."

Alpine Club, 23, Savile-row, W., 8.30 p.m.

University of London, University College, Gower-street, W.C., 5 p.m. Mr. F. W. Thomas, "Comparative Philology." (Lecture III.)

5.30 p.m. Mr. H. D. Eberlein, "American Architecture during the 17th and 18th Centuries."

Farmers' Club, at the Surveyors' Institution, 12, Great George-street, S.W., 6 p.m. Sir Trustram Eve, "State Control and Agriculture."

Geographical Society, Kensington-gore, W., 5 p.m. Lieut.-Colonel W. J. Johnston, "The New One-inch and Quarter-inch Maps of the Ordnance Survey."

Mechanical Engineers, Institution of (Graduates' Association), Storey's-gate, S.W., 8 p.m. Mr. R. J. Glinn, "Large Boiler Units."

TUESDAY, DECEMBER 9...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Colonial Section.) Sir E. Davson, "Problems of the West Indies."

Electrical Engineers, Institution of (North-Eastern Centre), Armstrong College, Newcastle, 7.15 p.m. (North Midland Centre.) Midland Hotel, Bradford, 7 p.m. Discussion on "The Linking-up Report." (Scottish Centre.) 207, Bath-street, Glasgow, 7 p.m. Mr. J. M. Scott-Maxwell, "Scientific Works Management."

British Acetylene and Welding Association, The George and Vulture Tavern, St. Michael's-alley, Cornhill, E.C., 7.45 p.m. Mr. G. J. Stanfield, "The Electrolytic Productions of Oxygen."

Civil Engineers, Institution of, Great George-street, S.W., 5.30 p.m. Discussion on Mr. H. H. Gordon's lecture, "Some Aspects of Metropolitan Road and Rail Transit."

Photographic Society, 35, Russell-square, W.C., 7 p.m. Mr. H. F. Farmer, "The Carbro Process."

Anthropological Institute, 50, Great Russell-street, W.C., 8.15 p.m. Mr. J. H. Hulton, "Leopard Men of the Naga Hills."

Colonial Institute, Central Hall, Westminster, S.W., 8 p.m. Mr. G. H. Knibbs, "Statistics and National Dealing."

Marine Engineers, Institute of, The Minories, Tower-hill, E., 6.30 p.m. Discussion on papers, "History of the Steamship," and "Electrification of Ships."

WEDNESDAY, DECEMBER 10.—ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Trueman Wood Lecture.) Sir Oliver Lodge, "Some Possible Sources of Energy."

Aeronautical Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. J. D. Worth, "Aircraft Undercarriages."

University of London, University College, Gower-street, W.C., 6.15 p.m. Mr. J. C. Stamp, "Fundamental Principles of Taxation in the Light of Modern Developments." (Lecture VI.)

Oriental Studies, School of, Finsbury-circus, E.C., 5 p.m. Mr. L. Binyon, "The Art of Asia. Lecture IV.—Chinese Art."

United Service Institution, Whitehall, S.W., 3 p.m. Rear-Admiral Sir W. E. Goodenough, "Light Cruisers."

Public Health, Royal Institute of, 37, Russell-square, W.C., 4 p.m. Dr. S. G. Moore, "Housing in relation to Maternity and Child Welfare."

THURSDAY, DECEMBER 11...Royal Society, Burlington House, W., 4.30 p.m.

Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Linnean Society, Burlington House, W., 5 p.m. 1. Professor W. A. Herdman, "Notes on the Abundance of Marine Animals and a quantitative survey of their occurrence." 2. Mr. J. Brontë Gatenby, "The Fertilisation of the Calcareous Sponges."

University of London, University College, Gower-street, W.C., 5.30 p.m. Professor A. Cippico, "La Poesia di Giovanni-Pascoli." (Lecture VII., in Italian.)

Automobile Engineers, Institution of, 28, Victoria-street, S.W., 8 p.m. (Graduates' Section.) Discussion on "Worm versus Bevel Drive."

Optical Society, at the Chemical Society, Burlington House, W., 7.30 p.m.

Electrical Engineers, Institution of, at the Institution of Civil Engineers, Great George-street, S.W., 6 p.m. Mr. J. M. Scott-Maxwell, "Scientific Works Management."

Historical Society, 22, Russell-square, W.C., 5 p.m. Dr. S. A. Khan, "The East India Trade in the 17th Century in its Political and Economic Aspects."

FRIDAY, DECEMBER 12...London Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Mr. Hilaire Belloc, "The River of London."

Malacological Society, at the Linnean Society, Burlington House, W., 8 p.m.

Astronomical Society, Burlington House, 5 p.m.

University of London, University College, Gower-street, W.C., 8 p.m. Professor G. D. Hicks, "An Introduction to Modern Philosophical Thinking." (Lecture VI.)

Auctioneers and Estate Agents' Institute, 34, Russell-square, W.C., 7.45 p.m. Mr. S. A. Smith "Acquisition of Land (Assessment of Compensation Act, 1919)."

Sanitary Institute, 90, Buckingham Palace-road, S.W., 3 p.m. Dr. H. Scurfield, "Mothers' Pensions."

Journal of the Royal Society of Arts.

No. 3,499. VOL. LXVIII.

FRIDAY, DECEMBER 12, 1919.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

MONDAY, DECEMBER 15th, at 8 p.m. (Cantor Lecture.) JOHN THEODORE HEWITT, M.A., D.Sc., Ph.D., F.R.S., Emeritus Professor of Chemistry, East London College, "Synthetic Drugs." (Lecture III.)

WEDNESDAY, DECEMBER 17th, at 4.30 p.m. (Ordinary Meeting.) CONSTANTINE GRUNWALD, late Chief of Intelligence Department, Russian Ministry of Trade and Industry, "The Present Economic Position of Russia, and some Aspects of its Future Development."

THURSDAY, DECEMBER 18th, at 4.30 p.m. (Indian Section.) P. J. HARTOG, C.I.E., M.A., Member of the Calcutta University Commission, 1917-1919, "Some Problems of Indian Education." The Right Hon. LORD MESTON, K.C.S.I., LL.D., will preside.

Further particulars of the Society's meetings will be found at the end of this number.

CANTOR LECTURE.

Monday afternoon, December 8th; DR. M. O. FORSTER, F.R.S., in the chair. DR. JOHN THEODORE HEWITT, F.R.S., Emeritus Professor of Chemistry, East London College, delivered the second lecture of his course on "Synthetic Drugs."

The lectures will be published in subsequent numbers of the *Journal*.

COLONIAL SECTION.

Tuesday afternoon, December 9th, 1919; LIEUT.-COLONEL L. S. AMERY, M.P., Under-Secretary of State for the Colonies, in the chair. A paper on "Problems of the West Indies" was read by SIR EDWARD DAVSON.

The paper and discussion will be published in the *Journal* of December 26th.

FOURTH ORDINARY MEETING.

Wednesday, December 10th, 1919; The Hon. SIR CHARLES ALGERNON PARSONS, K.C.B., LL.D., D.Sc., F.R.S., Vice-President of the Society, in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Bassett, Frank Owen, London.
Bassett, John Harrold, London.
Clark, Victor Albert Jarvis, London.
Gaunt, Frederick William, Farsley, near Leeds.
Haas, Adolph Louis, A.M.I.Mech.E., London.
Hainsworth, Charles, Farsley, near Leeds.
Hargreaves, Miss Violet, Eccleshall, Staffs.
Holmes, H., Moseley, Birmingham.
Ibbotson, Walter Dudley Boswell, Bowdon, Cheshire.
Kay, Max M., Manchester.
Maurice, Ernest Maurice, London.
Russell, Captain Guy, London.
Salmon, Harry, West Hartlepool.
Smith, John, M.I.Mech.E., Edgbaston, Birmingham
Turner, Augustus, M.A., London.
Waite, David E., Palmer, Mass., U.S.A.
Whittaker, Cecil John, Sunderland.
Wilding, John, Shotton, Flint.

The following candidates were balloted for and duly elected Fellows of the Society:—

Brocklebank, Captain H. Cyril R., R.N., O.B.E., Tarporley, Cheshire.
Croft, Albert John, Birmingham.
Dunning, Harold Frederick, London.
Grant, Gustavus John, Birmingham.
Mercer, Raymond G., Manchester.
Paxman, Edward Philip, Bournemouth.
Plant, A. Edmund, Poulton-le-fylde, Lancs.
Reed, T. A. Woolterton, London.
Saunders, Arthur D., Bexhill-on-Sea.
Skelley, Horatio Arthur, Hyde, Cheshire.

The Trueman Wood Lecture on "Sources of Power Known and Unknown" was delivered by SIR OLIVER LODGE, D.Sc., Sc.D., LL.D., F.R.S.

The lecture will be published in the next number of the *Journal*.

JUVENILE LECTURES.

The usual short course of lectures adapted to a juvenile audience will be delivered on Wednesday afternoons, January 7th and 14th, 1920, at 3 p.m., by Mr. Loughnan Pendred, M.I.Mech.E., Editor of *The Engineer*, on "Railways and Engines." The lectures will be fully illustrated with working models and lantern-slides.

Special tickets are required for these lectures. They can be obtained on application to the Secretary.

A sufficient number of tickets to fill the room will be issued to Fellows in the order in which applications are received, and the issue will then be discontinued. Subject to these conditions, each Fellow is entitled to a ticket admitting two children and one adult. Fellows who desire tickets are requested to apply for them at once.

PROCEEDINGS OF THE SOCIETY.

THIRD ORDINARY MEETING.

Wednesday, December 3rd, 1919; The Right Hon. Lord Lamington, G.C.M.G., G.C.I.E., in the chair.

The paper read was—

THE SEED-CRUSHING INDUSTRY.

By J. W. Pearson,
Chairman and Managing Director, The British Oil and Cake Mills, Ltd.

The seed-crushing trade is probably one of the oldest industries in the world, and yet, like many another whose importance has not always been fully realised from a national point of view, it was left for the outbreak of the most devastating war in history to bring about a recognition of its vital importance.

The earliest indications of the existence of seed-crushing as a trade may be traced to a period many years before Christ, and it is difficult to say which was the first of the three manufactured articles coupled together by the great Psalmist in his song of gratitude—"Bread to strengthen, wine to gladden the heart of man, and oil to make him of a cheerful countenance."

There is no doubt that wine and bread were for long a household production only and for personal use, but it is probable that the manufacture of oil was almost from the first carried on for purposes of barter, and it is, indeed, quite likely that commerce in oil was the first real trade of the world. The oil was, of course, the product of the olive, and in the first place was probably used for external application only. It is a moot point whether oil produced from the olive grown on the shores of the Mediterranean or from the coco-nut palm grown further East can claim the greater antiquity. At a later date its use as a foodstuff was recognised, and olive oil for human consumption very early became an article of every-day diet. For many centuries the business of crushing oilseeds was carried on from the point of view of oil production only. The residue was accounted of no value and thrown out as waste. It is only within comparatively recent years that a use for the dry residual product was found either as a fertiliser or as a feeding stuff. The story goes that a certain manufacturer, who had dumped his residue into an adjoining field, noticed the cattle that were engaged in the operation of turning the rude crushing-mill of those days eagerly feeding from the pile of refuse. Very little observation disclosed the fact that the consumption of this residue, far from being harmful, was apparently beneficial to the physical condition of the cattle, and thereafter the residue, or "cake," as it is termed, quickly obtained recognition as a cattle food of considerable value.

The earliest centre in Europe where seed-crushing may be considered to have become an established industry was Holland, where mills were originally erected to crush seeds grown locally. While there are indications of the existence of oil mills in England in the fifteenth century, the first authentic documentary records of any factory date back to the seventeenth century, and relate to a business at Evesham (now belonging to Messrs. Foster Brothers' branch of The British Oil and Cake Mills, Ltd.), and by the middle of the eighteenth century the trade had acquired considerable importance. The chief manufacturing centre in England has always been Hull, where the principal seeds crushed were the product of districts abutting upon the Baltic Sea, from which part of the world Hull was the most convenient port for consignment. At the time of the outbreak of war there were some sixty different firms engaged in the trade in Great Britain, ranging in importance from small country owners with a mill capacity of 5,000 tons of seed per annum, to the establishments of the British Oil and Cake Mills, Ltd., whose combined branches handle something like 45 per cent. of the entire industry. The importance of ensuring that oilseed factories should be kept fully at work during the war

PROCEEDINGS OF THE SOCIETY.

THIRD ORDINARY MEETING.

Wednesday, December 3rd, 1919; The Right Hon. Lord Lamington, G.C.M.G., G.C.I.E., in the chair.

The paper read was—

THE SEED-CRUSHING INDUSTRY.

By J. W. Pearson,

Chairman and Managing Director, The British Oil and Cake Mills, Ltd.

The seed-crushing trade is probably one of the oldest industries in the world, and yet, like many another whose importance has not always been fully realised from a national point of view, it was left for the outbreak of the most devastating war in history to bring about a recognition of its vital importance.

The earliest indications of the existence of seed-crushing as a trade may be traced to a period many years before Christ, and it is difficult to say which was the first of the three manufactured articles coupled together by the great Psalmist in his song of gratitude—"Bread to strengthen, wine to gladden the heart of man, and oil to make him of a cheerful countenance."

There is no doubt that wine and bread were for long a household production only and for personal use, but it is probable that the manufacture of oil was almost from the first carried on for purposes of barter, and it is, indeed, quite likely that commerce in oil was the first real trade of the world. The oil was, of course, the product of the olive, and in the first place was probably used for external application only. It is a moot point whether oil produced from the olive grown on the shores of the Mediterranean or from the coco-nut palm grown further East can claim the greater antiquity. At a later date its use as a foodstuff was recognised, and olive oil for human consumption very early became an article of every-day diet. For many centuries the business of crushing oilseeds was carried on from the point of view of oil production only. The residue was accounted of no value and thrown out as waste. It is only within comparatively recent years that a use for the dry residual product was found either as a fertiliser or as a feeding stuff. The story goes that a certain manufacturer, who had dumped his residue into an adjoining field, noticed the cattle that were engaged in the operation of turning the rude crushing-mill of those days eagerly feeding from the pile of refuse. Very little observation disclosed the fact that the consumption of this residue, far from being harmful, was apparently beneficial to the physical condition of the cattle, and thereafter the residue, or "cake," as it is termed, quickly obtained recognition as a cattle food of considerable value.

The earliest centre in Europe where seed-crushing may be considered to have become an established industry was Holland, where mills were originally erected to crush seeds grown locally. While there are indications of the existence of oil mills in England in the fifteenth century, the first authentic documentary records of any factory date back to the seventeenth century, and relate to a business at Evesham (now belonging to Messrs. Foster Brothers' branch of The British Oil and Cake Mills, Ltd.), and by the middle of the eighteenth century the trade had acquired considerable importance. The chief manufacturing centre in England has always been Hull, where the principal seeds crushed were the product of districts abutting upon the Baltic Sea, from which part of the world Hull was the most convenient port for consignment. At the time of the outbreak of war there were some sixty different firms engaged in the trade in Great Britain, ranging in importance from small country owners with a mill capacity of 5,000 tons of seed per annum, to the establishments of the British Oil and Cake Mills, Ltd., whose combined branches handle something like 45 per cent. of the entire industry. The importance of ensuring that oilseed factories should be kept fully at work during the war

was quickly recognised, but, curiously enough, it was in the first place at the instance of firms engaged in the soap trade, who pointed out that the supply of glycerine for the manufacture of explosives was dependent upon the maintenance of adequate supplies of oils for soap manufacture. It was therefore considered necessary to include the trade of seed-crushing in the group of "controlled industries" under the Ministry of Munitions. Later on, the other aspect of the trade became more dominant, and the importance of the mills as a source of food supply—firstly, for the production of edible oils required for the manufacture of margarine; and, secondly, for the cakes so necessary to the production of meat and milk—resulted in the transfer of control from the Ministry of Munitions to the Ministry of Food. While during the days of its early growth this trade was mostly centred at the principal shipping ports, Hull, London, and Liverpool, there has been a gradual extension of factories at the outports. To-day the centres of manufacture are Aberdeen, Bristol, Burntisland, Bridgwater, Colchester, Dundee, Gainsborough, Glasgow, Gloucester, Grimsby, Hertford, Hull, Ipswich, Kirkcaldy, Leith, London, Lincoln, Liverpool, Lynn, Manchester, Rochester, Selby, Southampton, Warrington, Weybridge. The reason of this change is fairly obvious, as, up to the middle of last century, the principal shipping lines from the countries of origin only visited the three chief ports, and the natural tendency was to create factories as near as possible to the point of arrival of these heavy goods, and where also the main centre of consumption for the oil product was close at hand. In those days the few country mills had to buy their seed in one of the three ports and tranship round the coast by small steamer. The cake was consumed in districts fairly adjacent to the country mill, but the oil, to a great extent, had to be returned again to Hull or London. With the improvement in shipping facilities the outports developed, and, in addition to a certain amount of regular liner traffic, it became possible to charter steamers with facilities to load to other direct ports on a basis that enabled supplies of raw material to be taken in almost as cheaply as the same goods could be purchased at Hull or London. Factories of considerable magnitude have sprung up at the principal outports above named, and while they still have to send away a large proportion of the oil, the fact of their proximity to the cake-consuming districts enables a very effective competition to be put up as against Hull and London.

I should like to divide this paper into three main sections, each of which may be shortly examined—viz., the materials, the plant, and the products.

The Materials.—I have already remarked that the first known source of oil was the olive or coco-nut, and it was not until somewhere about the sixteenth or seventeenth century that it became generally recognised that many other vegetable seeds and fruits might be used for the production of oils. It will, I think, be convenient to classify the range of oil-bearing seeds into two main groups—first, those that are rich in oil; and, second, those that are comparatively poor in oil. This classification is useful, not because there may follow any analysis as to the countries of origin, but rather because it distinguishes two broad groups of seeds—the one of which is used by millers whose main business is the production of cake, and the other by millers who are most concerned with the production of oil.

Incidentally it may be observed that the seeds described as rich in oil usually require to be treated in a different class of plant from that required for dealing with seeds described as comparatively poor in oil.

Without attempting to cover the whole of the range of oil-bearing seeds, the principal descriptions may be grouped on the following lines: Those rich in oil—that is to say, containing 45 per cent. of oil or over—comprise ground-nuts, sesame, castor, mowrah, copra, palm-kernels, the three former producing liquid oils and the three latter solid oils. The group less rich in oil—containing less than 45 per cent.—comprise linseed, cottonseed, niger-seed, poppyseed, rapeseed, and soya, all of which produce liquid oils.

The major portion of the oilseed crops of the world are produced within the British Empire, and it is interesting to note that while a few seeds, notably linseed, rapeseed, and sunflower-seed, are grown in the Temperate Zone, the remainder are grown almost exclusively in the Torrid Zone, and therefore have to be imported by Europe for consumption there. England grows no oilseed crops, and is therefore dependent upon import for the whole of her oil production; but the continent of Europe raises considerable quantities of linseed, rapeseed, poppy, and sunflower. The claim to regard the oilseed trade as one of the key industries of the country is surely established when due regard

is given to the huge quantities of oil required by the manufacturers of soap, paint, linoleum, varnish, lubricants, and burning oils, among the technical trades; and baking, frying cooking fat, and margarine manufacturers among the edible trades. The total consumption of oils for these purposes in Great Britain is estimated at 600,000 tons per annum.

As the world's requirements in oils and fats grow every day, the story of past development has been the loss to the technical manufacturer of one after another of his markets for cheap oils, in proportion as scientific achievement has enabled each in turn to be rendered suitable for the edible trades; so a substitute has always to be found to replace for the soap pan the oil now used for margarine. A multitude of varieties of less known oilseeds are found in the world in enormous quantity, but they are either in districts at present inaccessible, or else in a condition or form that renders them almost unserviceable; but there is little doubt that in years to come, with future scientific developments and treatment, these will take their place among the important sources of oil supply. I have in mind such articles as the cohune, coquilla, and coquita nuts, the fruits of some of the many varieties of palm which are found in enormous quantity in practically all the tropical countries, and kindred seeds and nuts which have as yet proved of little interest to the ordinary seed crusher, because the heavy shell in which the kernel is enclosed has up to the present offered almost insuperable difficulties in the way of cracking and effective separation of kernel from shell. Similarly, oiticicia, ucuhuba, and illipi, which, though rich in oil, present extraordinary difficulties both to the crusher and to the extractor on account of the physical constitution of the material itself, which, when crushed, becomes a clay-like mass from which the extraction of oil is exceedingly difficult, if not commercially impracticable. Similar difficulties were encountered in the early stages of treating many of the seeds which are now so well known and freely handled, and the foregoing varieties are mentioned merely to show that there is still great scope for the application of scientific knowledge and research to the methods and processes in use for the production of vegetable oils.

Upon the general method of purchase of the raw material perhaps one word should be said, as the business of importing oilseeds is generally regarded as a separate trade, and is only in a few instances handled directly by owners of oil mills. The business of the merchant shipper is to purchase the seed in the country of origin direct from the native grower, to arrange for its transport and shipment, and last, but by no means least, to make the necessary financial arrangements to cover the period during which the goods are in transit, as the shipper does not usually receive payment until arrival of his cargoes at their destination. Special organisations have been set up to deal with the weighing and sampling of the consignments on arrival, with an elaborate system of analysis and examination under which a certificate is issued for the joint purpose of both buyer and seller, declaring the true proportion of pure material in the parcel examined, and at the same time both the nature and percentage of any admixture of foreign matter. This system of purchase on analysis has undoubtedly contributed largely to the general improvement in both quality and condition of the merchandise brought to this country.

The Plant.—In the early days when the only oil produced was obtained from the olive, the process was comparatively simple. The original breaking plant was the horizontal stone, probably operated by two women sitting on opposite sides, similar to that employed for the grinding of corn into flour. The broken mass was removed from the stone, packed in canvas bags and subjected forthwith to pressure under a long plank used as a lever. The method adopted followed pretty closely that in use for pressing grapes in the manufacture of wine. I think the earliest allusion to the apparatus is to be found in the writings of Vitruvius in his chapter on "The Farm Buildings," round about 30 B.C., of which the following translation was made by William Wilkins in 1812:—

"The press room should be near the kitchen, for then it will be conveniently situated for the preparation of oil. The wine cellar should adjoin the press room, and have their windows facing the north; for if they were exposed to the sun, the wine would be affected by the heat and become vapid. The store rooms in which oil is kept should be made to face the south, so that they may receive their light from the warmer quarter of the heavens; because oil is injured if suffered to congeal, but tempered by exposure to a certain degree of heat. The size of these rooms must be proportioned to the produce of the olive and vineyards, and the number of casks which contain it. Every vessel containing twenty amphoræ will occupy four feet. If the presses be worked with levers and beams, without the aid of screws, the press room ought not to be less than forty feet long, in order to afford space for the action of the levers, nor should its

width be less than sixteen feet, for then those who are employed at the press will not have their operations obstructed through want of room. If it be necessary to have two presses, the width of the room should be twenty-four feet."

[Later references to similar plant may be found in Pliny's "Natural History of 77 A.D."]

The first improvement upon this lever press was the substitution of the wedge press, where horizontal pressure was applied by means of a wedge driven downwards at first by blows from a heavy hammer, and later by the fall of a mechanically-lifted weight—an apparatus similar in general principle to the pile-driving machine of the present day. The screw press in place of the wedge followed naturally, as also the substitution of a pair of revolving vertical stones for the old horizontal mill stone. With such appliances the output was naturally small, and oil-producing mills were only sparsely scattered here and there close to the seat of production of the raw material. It was not until about the year 1600 that seed crushing can be regarded as having become an established industry, when a considerable number of mills were known to be in operation in Holland.

It was in 1652 that Pascal discovered the law relating to the uniform distribution of pressure in a fluid upon which the principle of the present hydraulic press is based. It was not until nearly 150 years later that an English patent was taken out in the name of an engineer, Joseph Bramah, who in 1795 lodged a claim for a special method of application of water or other liquid pr ssure to various mechanical devices described, for the transmission and application of power in a form giving results superior to any obtained by methods then hitherto known. It was, however, his invention of the U-shaped leather packing which rendered this system really efficient, and this was undoubtedly the most important invention in the history of seed-crushing. It was this patent that formed the basis for the introduction of what is believed to be the first hydraulic press, manufactured about the year 1830 by the French engineer Chambauvet. This press had a ram of 16 centimetres diameter (about 6¼ in.), and was worked at a pressure of 60 kilos per square centimetre (about 853 lb. per square in.). Within a few years the use of accumulators for the distribution of pressure was discovered by the Lyonnese engineer Falquiere, who at the same time built presses of a larger and heavier patt rn, starting with rams of 220 millimetres (about 8¾ in.) and increasing by steps up to 320 millimetres (about 12½ in.), which he worked at a pressure of 210 kilos per square centimetre (about 2,987 lb. per square in.). It was no doubt the introduction of this system of hydraulic pressing that caused the enormous and rapid spread of the industry all over the world. In the early years of the nineteenth century there were many small factories sprinkled over England deriving their power frequently from windmills, operating plants which consisted of a set of preliminary breaking rollers, generally arranged in pairs of two horizontally, from which the first crushed seed was transferred to a pair of verti al edge stones, and thence to a kettle or open pan where the meal was cooked by the application of free steam. The prepared meal was thereafter filled into a small bag of canvas material which was placed between the plates of what is now known as the old-fashioned vertical box press, in which from four to five cakes were pressed at a time. The first important improvement was the introduction of the open press, which consists of a series of flat plates slightly hollowed at the centre to give a grip on the material and fitted to take sixteen cakes at one pressing. The small horizontal pair rolls gave way to a machine of much greater power, the present pattern usually consisting of a series of five rollers 4 ft. in length and about 18 in. in diameter, arranged vertically, which obviously handles a much greater volume of seed and treats it with much higher efficiency. The prepared meal, instead of being filled into a small bag, is moulded through an open frame on to a plain cloth wrapper, the ends of which are afterwards folded over the moulded cake to facilitate transfer to the plates of the hydraulic press, where a total pressure of about 300 tons is applied. The residual cake when withdrawn from the press is taken to the paring machine, which is simply a cutting knife arranged with a horizontal reciprocating motion in order that the rough oily edges may be removed and a symmetrical appearance obtained. Under modern conditions a unit of machinery consists of one set of rollers, one kettle or steam cooker with its moulding machine, one battery of four hydraulic presses fitted to take sixteen cakes each, hydraulic pumps, accumulator, and paring table. Each unit is operated by a squad of three men, who between them turn out cakes at the rate of 112 per hour. Under the most modern practice mills are arranged to contain eight to ten such units, and the latest arrangements adopt such devices as automatic moulding machines and automatic paring machines.

which enable one man to serve two or three batteries of presses instead of only one. This is the type of machinery most commonly used in England, and is conveniently adapted for the treatment of the group of seeds earlier described as comparatively poor in oil. A variation in this plant has been brought into use during the last half century, where a type of hydraulic press known as the cage press has been substituted for the open type. This is particularly adapted for the treatment of the seeds described as rich in oil, where the prepared meal spreads so rapidly under the influence of pressure that it cannot be retained between the plates of the open press. This type of cage press is built in barrel form of staves with minute apertures between each to permit the exudation of the oil. The moulded cakes are placed inside the barrel and submitted to hydraulic pressure, when the bulk of the oil is expressed. The residual cake is then usually withdrawn, re-ground, and submitted to further pressure in the ordinary type of open press. This is the class of plant that is most conveniently adapted for the treatment of such seeds as sesame, castor, ground-nuts, palm kernels, copra, mowrah, etc. Mechanical science is constantly on the alert for improvements in every section of machinery, but has for the most part confined its attention to the press. Several recent patterns are in more or less experimental use, although some—such as the Anderson expeller, which is really a horizontal barrel press relying upon the thrust of a screw with a gradually diminishing pitch to obtain the pressure necessary for the expulsion of oil; or the Schneider press, a similar pattern of barrel press arranged vertically and relying upon the thrust of a direct-acting piston against a thin film of material—have come into fairly extensive use for the preliminary pressing generally known as clodding.

No system has yet been discovered which will enable the whole process of oil manufacture to be conducted automatically from the cooking kettle to the point of oil expression, and this is the stage where there is much scope for economy in manufacture.

It is perhaps extraordinary that such an extensive operation as that of oil-milling can be conducted for such a comparatively low cost. In a well-appointed mill, on a pre-war basis, the whole operation of receiving, crushing, cooking, pressing, oil-filtering, and delivery of the produce, inclusive of interest on capital employed, depreciation, power, labour, consumption of stores, and all general working charges, could be carried out for less than £1 per ton, and this upon a raw material whose original average cost would not exceed £12 per ton.

In discussing plant in general use in oil mills, I must not omit mention of another system which for certain seeds has come much more into favour in recent years, viz., the process of chemical extraction. The plant here used is simply the application on a commercial scale of the same principles that are adopted in the laboratory for the extraction of oil from oilseeds when making an estimation of the contents. The preliminary treatment plant for breaking or crushing the material is similar to that adopted in hydraulic mills, but the crushed material is thereafter transferred to large pots or extractors, where it is subjected to the action of a chemical solvent, the ordinary forms of which are petroleum ether, carbon bisulphide, carbon tetrachloride and trichlorethylene. The first is in more general use, while all have certain advantages and disadvantages. In this process the residue is left in the form of meal and not in the form of cake, and one of the principal drawbacks is the difficulty of getting rid entirely of all traces of the solvent both in the meal residue and in the oil product. The process is in much more general use in North Europe than in England, because the farmers there are more accustomed to use feeding-stuffs in the form of meal, while in England the whole cake, bearing a brand, is generally preferred. In the oil there is frequently found a faint aroma from the solvent which is difficult to remove entirely in the process of refining. For a long time oil obtained by the extraction process was regarded as unsuitable for edible purposes, but improvements in the manufacture and purity of the solvent, and also in refining processes, now enable the oil to be used by almost all the edible trades.

In comparing the manufacturing costs of these two systems, the principal standing charges may be regarded as much the same for both, but while there is in favour of the extraction system a slight saving owing to the fact that no press bagging is used, there is a much greater coal consumption and a heavy additional charge owing to the loss of solvent, which is perhaps the most expensive item of the system. In normal pre-war days it was generally reckoned that the total manufacturing costs under the extraction process were at least 50 per cent. greater than those under the hydraulic system.

With this somewhat sketchy description of the machinery, a word on the process itself must be said. Roughly, the operation may be divided into five sections from the point of arrival of seed at the mill—cleaning, rolling, cooking, pressing, paring. While at first little attention was paid to the condition of the seed on arrival, modern mills now possess the latest machinery for screening and winnowing the seed as it passes through the warehouse. All the dust and extraneous admixture is removed by fans and sieves, so as to render the seed itself as pure commercially as possible before passing to the rolls. The rolling operation requires considerable attention and skill, as each kind of seed needs slightly different treatment. The object is so to crush the seed that every oil cell is bruised or fractured. The succeeding process in the hydraulic press will not avail to extract the oil unless the walls of the oil cells are properly broken down, hen e whole or partially crushed seeds passing through the rollers represent loss in oil to the crusher. On the other hand, over-rolling is an almost equal evil, as in such cases the oil cells are not only bruised and broken, but the whole mass is converted into a dough-like pulp from which the process of extracting the oil may be likened to the difficulty of squeezing water out of a soapy sponge. The cutting action which may be obtained by driving the rolls in surface contact at different speeds produces a gritty meal, and the skilled manager must learn to recognise the quality of texture of his rolled material that indicates sufficient bruising without over-treatment. The cooking process requires equal care. The seed is worked slowly round and round in the open pan or kettle, and subjected to the direct action of live steam, occasionally with the assistance of jacket heat. The temperature varies for different seeds, but is usually in the neighbourhood of 170°–180° F. The free steam, impinging upon the mass in the kettle, has the effect of not only raising the temperature and cooking the mass, but also of operating to expand and further break up the already fractured oil cells. The proper regulation of the kettle at this stage of the process ensures that while the dry meal is fed in at the top it shall travel round slowly with a corkscrew motion until, on reaching the bottom of the pan, the cooking process is exactly complete. The inflow at the top of dry meal and the draft from the bottom of properly cooked meal forms a perfectly continuous process. The presence of the steam also causes a certain amount of moisture to be absorbed by the meal. This has to be regulated to a nicety, as a given degree of moisture facilitates the expression of the oil, while even a slight excess substantially retards the operation.

Less individual skill is required in the pressing section. The principal point needing attention is the care with which each moulded cake is placed in exact position between the press plates—a fraction off the true line causing an alteration in the distribution of pressure on the surface of each cake, owing to the plates being hollowed in the centre. The even distribution of the mass of meal over the whole surface is of the greatest importance in securing regularity. Even with the most carefully prepared cakes there has been found a difference of nearly 4 per cent. in oil content between one corner of a cake and another. This is solely due to the difference in mass upon compression of the material. The pressure usually applied is about 1½ tons to the square inch in the press cylinder. With a 16-in. cylinder this gives a total pressure of some 300 tons distributed over the surface area of the cake, and works out at about 17 cwt. to the square inch on the cake surface, although some materials, such as palm-kernels, require much higher pressure. It has been found in practice, as already indicated, that the expression of oil depends more upon the previous careful preparation of the material than upon the actual pressure employed on the press.

The paring operation is necessary to complete the process, partly for the sake of symmetry in the finished article, but more particularly to trim off the oily sides and edges which exude under the influence of pressure applied in the press. Generally about 20 per cent. of the pressed cake has to be removed at this operation, and the oil contained in these oily edges when trimmed off will usually be about 20 per cent. As the usual object is to turn out a cake with an oil content of about from 5 per cent. to 10 per cent. average, the machines are carefully adjusted to remove just so much of the pressed cake as will exceed this figure and yet leave the maximum possible remainder for the sake of the output obtained. The parings are, of course, carefully ground up and returned to the kettle to be worked over again.

Each kind of seed requires individual treatment, and the quality of the finished product depends largely on the exercise of care and skill in selection, and cleanliness and regularity throughout the crushing process.

The Products.—It is in handling the products of the mills that the most interesting develop-

ments have taken place in recent years, more particularly perhaps as regards the oil product, as the great and increasing demand for oils and fats of all descriptions during the last century has been the reason for the large increase not only in quantity but in variety; indeed, many oils which less than a century ago had but little commercial value have now been brought into extensive use, not only for technical but also for the finest edible purposes.

The most important developments have been connected with the edible oil refineries. The earliest refiners confined their attention to the production of clear oil suitable for the manufacture of soap, and the main object was the removal of colour. This was usually done by subjecting the oil to a treatment of caustic soda or weak acid, after which filtration through an ordinary filter press completed the process. The plant was simple, consisting only of a series of open iron or lead-lined tanks. Oils intended to be used for edible purposes were at first treated in a very casual fashion, and for many years the only refining process used in England was the application of weak caustic soda for the purpose of neutralising the free fatty acids in the crude oil, followed by a steam and water wash and filtration over fullers-earth. This produced an oil which was ordinarily used for fish-frying and common cooking purposes. The development of refining plants made much more rapid progress in North Europe, where the use of oil for edible purposes was so much more general than in England. Here the prejudice of the Briton was so strongly in favour of butter, and so markedly averse to any vegetable substitute, whether described as margarine or sold under some other name, that the industry of producing margarine and other edible fats made but very slow headway in the United Kingdom, and there was consequently but little incentive for refiners to improve their methods. Here, again, the influence of the war has had a very marked effect upon the trade of this country. The consumption of margarine in England to-day is more than three times what it was at the outbreak of war, and the margarine manufacturing plants are now capable of producing over 10,000 tons of margarine per week, whereas not more than 2,000 tons were produced before the war. As a natural consequence, the extension of up-to-date refining plants has been rapid and marked. Numbers of refineries have sprung up in the different manufacturing centres, specially designed to produce what is known as deodorised oil. In these plants the crude oil is subjected first to treatment with a weak alkali for the purpose of completely neutralising the free fatty acids. The neutralised oil is then washed, cleaned, and dressed with steam and fullers-earth, and afterwards subjected to the action of super-heated steam under vacuum, in the course of which all objectionable vapours are distilled off, leaving a pale clear oil completely neutral in constitution and flavour. Perhaps the most fascinating of all the oils is that obtained from cottonseed, on account of the multiplicity of its sub-products. Here the crude oil is a dark blackish colour tinged with red. The colouring matter, to which the name gossypol has been given, is of a resinous nature, and, curiously enough, is not derived from the black fibrous shell of the seed, but is contained in a mass of small brown cells which persist through the whole body of the kernel. It combines readily with caustic soda, and is therefore removed in the same operation as the neutralisation of the fatty acids. In the case of most crude oils subjected to this process, the residue is a semi-soap commercially known as soap stock, and is an article readily sought for by the soap manufacturer. Cotton oil residue, however, containing the whole of the colouring matter, is quite useless for the manufacture of soap, and up to fifty years ago was regarded as waste product, and had to be thrown away as refuse. To-day it has a high value, and is subjected to a special process of distillation at a high temperature over a current of superheated steam. The fatty matters are distilled over as a light-coloured grease, and the residue left behind as a black pitch. The constitution of this pitch can be varied in the course of the distillation process, and turned out either as hard bright brittle pitch, used for the manufacture of the coarse waterproof wrapping in which cotton goods are exported, also for railway covers, black varnishes, etc., or, again, as rubber pitch or elastic pitch, used in the manufacture of cheap rubber substitutes and as an insulating material in electrical work. The grease is distilled over again several times, each operation raising the melting-point of the fatty acids, thus producing fine white grease suitable for soap and candle makers. It may also be pressed in hydraulic presses, turning out on the one hand fine oleines, and on the other hard white stearine cake valuable for the manufacture of soap or candles. Thus every ingredient of a once waste product is now turned to useful account.

Probably, however, the most interesting process of recent date is that known as the hardening or hydrogenating process, which enables most liquid oils to be turned into a solid substance almost indistinguishable from tallow, and relies in its operation upon a purely chemical change. All liquid oils contain a large proportion of unsaturated fatty acids, usually described as oleic, which by the absorption of two extra atoms of hydrogen are capable of conversion into stearic acid. While the unsaturated oleic acids retain the physical form of liquids, the saturated stearic acids containing their full complement of hydrogen have the form of solid waxes or tallows. The hydrogenating process is the result of an invention based upon the discovery of a system under which it was possible to introduce the necessary additional hydrogen to complete saturation. The plant is not dissimilar to that used in the deodorising and refining process, but in this case the neutralised oil, instead of being subjected to the operation of a passage of superheated steam, is exposed to a stream of heated hydrogen gas in the presence of a catalyst. The catalyst seems to be a perfectly neutral body, whose mere presence appears to facilitate the absorption by oleic acids of the extra hydrogen necessary to complete saturation, and without which no action takes place. The catalyst usually employed is very finely divided nickel. I doubt whether the exact action of the catalyst is yet clearly understood, because at the end of the process it apparently remains in exactly the same condition as at the commencement, subject only to a gradual loss of efficiency through oxidisation. Several large plants have been erected in England and in North Europe for the treatment of oil by the hydrogenating process, and the general effect is to enable liquid oils to be used by either soap makers or margarine makers in place of hard oils. In considering the world's supplies as a whole, the liquid oils are in much greater abundance than hard oils, but the latter, owing to their physical consistency and high melting-point, are urgently required by both the soap and margarine trades in order to enable their products to be turned out in such a condition as to remain solid even under fairly high temperatures. In consequence, these hard oils as a group have always commanded a premium of £10 to £15 per ton in the open market over the liquid oils. A process such as this, therefore, which enables liquid oils to be converted into hard at an expense that probably does not normally exceed £5 per ton, must surely in the future prove to be of inestimable benefit to the trade.

The enormous increase in margarine and edible fats manufactured in England has created a demand for fine edible oils far in excess of that which previously existed, and while in past years considerable quantities of the finer oils were manufactured in North Europe and shipped to England, it is hoped that the manufacture of these oils in England, being so largely the product of raw materials grown in our own Colonies, will be retained as a permanent trade for the United Kingdom.

The other product of seed crushing upon which a few words must be said is the residue or cake so largely used for cattle-feeding. The cakes most ordinarily produced in this country —*i.e.* linseed cake and cottonseed cake—are so well known as to need but few remarks. It is, perhaps, not generally recognised that cake as a feeding-stuff is not only a concentrated food but a cooked food. Its intrinsic value depends largely upon the extent of concentration, which varies entirely with the individual seed used. Up to the middle of the last century the production of feeding cake was looked upon in a very casual fashion, but little attention being paid to either purity or condition. To the farmer "oil cake" represented the product of a linseed mill, probably containing just such other added ingredients as it might suit the miller to introduce. Competition in the matter of price in the earlier years of last century resulted in a considerable amount of adulteration, and, indeed, as the bulk was sold under the generic term "oil-cake," there was little importance attached to the purity of the article. The earliest attempt made for the protection of the consumer was the passing of the Merchandise Marks Act in 1887, which provided that any statement made by way of trade mark or brand should be effective as a warranty of the truth of such statement. Up to that date most millers had been in the habit of branding their cakes "pure," and perhaps it says but little for the conscience of the traders of that day that, after the passing of the Act, the word "pure" disappeared from many well-known brands of cakes. This was followed by the first Fertilisers and Feeding Stuffs Act in 1893, which enacted that any feeding-stuff sold under a description implying manufacture from one substance or seed was warranted to be pure and manufactured from that substance only, unless otherwise declared at the time of sale. Thereafter a cake sold as

linseed cake had to be made from linseed only, and contain no extraneous admixture. A marked improvement took place from that time onwards; and the attention of seed crushers has been largely directed to the scientific aspect of cake manufacture. The consulting analysts to the several agricultural societies, and particularly the Royal Agricultural Society, were constantly reminding their farmer clients of the importance of ascertaining the chemical analysis of the feeding-stuffs they purchased. The presence of sand and the presence of excess moisture, weed seeds, and other extraneous matter, was continually pointed out, and for the crushing trade it must be said that an endeavour was made to bring their products up to the highest possible pitch of excellence. The present Fertilisers and Feeding Stuffs Act, passed in 1904, enforced for the first time upon the manufacturer an obligation to give a guarantee, within fairly broad limits, as to the chemical analysis of the article sold in its essential ingredients, but there still exists a considerable difference of opinion between manufacturers and scientists as to the commercial value of such analyses. As a general guide, a statement as to the contents of oil, albuminoids, carbo-hydrates, is undoubtedly useful, but there may be a tendency to place too much reliance upon the mere figure of the chemical analysis. Any practical farmer knows perfectly well that linseed oil is of much greater feeding value in cake than cotton or palm-kernel oil: or, again, that a unit of albuminoids in linseed cake or ground-nut cake is of much greater feeding value than a unit of albuminoids in cotton cake or rape cake, and yet for the purposes of chemical examination both rank as of the same value. By far the most popular cake in England is linseed cake, which shows no sign of being routed from its premier position even by the introduction of more modern articles such as sesame and ground-nut cake. Linseed cake serves an all-round purpose which is attained by no other, and may be used either as a fattener or a milk producer. For dairy purposes ground-nut cake and coco-nut cake have become exceedingly popular, and will become more so as the industry increases in England. The newer production, palm-kernel cake, is still a difficult market. It is unpleasant in the mouth, woody and unpalatable to both feel and taste. It is not consumed with relish by either cattle or sheep, and possibly the high proportion of fatty acids in the oil content may have something to do with its slightly unpalatable flavour. As a pig food it has always had an enormous outlet in Germany, and while its qualities in that direction have been demonstrated over and over again in the last few years, it still remains to be seen whether it will be able to oust barley-meal from its position as the pig-feeder's favourite when once the supplies of ordinary feeding-stuffs reach normal levels again. When properly ground there is no doubt as to the feeding value of palm-kernel cake, and great efforts will be made to extend its use in England in order to ensure that this country may be able to retain the palm-kernel crushing trade which has been carried on here during the last four or five years, and which previously was almost an entire monopoly for Germany.

A trade round which much debate has centred has been that of the production of cottonseed cake. The practice in England has differed from that in most other crushing centres of the world. The difference in systems is usually described as the production of decorticated cake or undecorticated cake. The American crusher decorticates the whole of his seed, crushing the kernel alone and producing thereby a cake rich in albuminoids and highly concentrated as a feeding-stuff. The shell, however, is largely wasted or has to be sold at a very low price. The practice in England has been to crush the whole seed at one operation, kernel and shell together. This system produces cake of lower value with a lesser degree of concentration, and consequently a more bulky feeding-stuff. It retains, however, certain astringent properties which are highly valued for use with the soft lush grass of this country as a sheep or cattle food, and when fed to grazing beasts it has no effective substitute. The result has been that a relatively higher price is paid here for undecorticated cake than for the decorticated, and consequently the American process has never found favour on this side.

The cake product of the oil mill is usually sold as a straight cake under the name of the seed from which it is made, thus: linseed cake, cotton cake, soya cake, etc. There is, however, an enormous business peculiar to this country in the production of a cake known as compound cake. This is cake manufactured from a selected mixture of straight cakes and other feeding ingredients such as treacle, locust beans, rice meal, millers' offals, etc., and has special advantages, more particularly for the small user. It claims to be a properly balanced food where the oil, albuminoids, and carbo-hydrates are

arranged in the most economical ratio either for fattening purposes or for milk production. The small farmer purchasing his linseed cake, cotton cake, or other straight cake separately, has to instruct his stock hand as to the proper proportions to mix for economical feeding, and he usually finds that the rough-and-ready weighing methods of his stockman are apt to result in either an inefficient or extravagant mixture. A properly balanced cake controls this matter effectively, and the importance of the point is quickly realised when it is recalled that a fair cake ration is 10 lb. per day per head of stock out of a total feed of abo it 50 lb. including bulk food, such as roots and hay.

Up to the outbreak of war the seed-crushing industry was carried on in this country principally for the sake of cake production, because as a nation we were a meat-consuming people, and the principal business of the miller was to provide material to enable the farmer to turn out meat and milk. On the other hand, the European seed-crusher was in business mainly as an oil producer. There the number of cattle fed bore a very different ratio to the human population, and it was the requirements in the shape of oil for direct use and for the manufacture of edible fats that was really the basis of the existence of the extensive co itinental oil-milling industry. It may be noted in passing that the continental miller was generally described under the title of "oil manufacturer," whilst in England he was known as a "cake manufacturer" or "seed crusher." This accounts for the fact that while England crushed mainly the seeds included in the group described as comparatively poor in oil, the European miller took the higher class of article such as palm-kernel, copra, ground-nut, etc. The last five years have brought about a substantial change in the English industry. Numbers of new plants have been erected whose major object is the production of oil, particularly for edible purposes and margarine manufacture, and this should mean a general expansion of the trade.

I have not touched upon many interesting problems connected with this business, such as the reason for oil appearing in certain vegetable seeds, when and whence it comes, why the divergence in quantity, or the extraordinary difference in character and constitution.

There is not scope within the limits of a paper such as this to do more than touch the fringe of so interesting and extensive a subject, but I venture to hope that I have been able both to indicate the need of continued scientific investigation and also to justify the claim of the seed-crushing trade to be regarded as one of the most important key-industries of the British Empire.

DISCUSSION.

MR. E. C. DE SEGUNDO said that in order to deal shortly with so vast and complex a subject as that of oil-seed crushing, not only a complete mastery of all its details was required, but also a happy selection of words. Having regard to the leading position which Mr. Pearson held amongst our great captains of industry, it was perhaps not to be wondered at that in the excellent *résumé* he had given to-day he should have shown himself to be possessed of those rare gifts in a marked degree. In his paper Mr. Pearson had referred to the process of transforming soft oils into hard oils or fats. He would like to ask some of the eminent chemists whom he saw present whether it was true that recent discoveries tended to show that there was a possibility of making the cycle reversible, or in other words of dehydrogenating the hydrogenated compound. If some process of that kind could be worked out commercially it would have a great influence on the future development of the seed-crushing industry. Dealing with the future of cotton seed as a raw material for the production of oil and cake, he said Mr. Pearson had referred in his paper to cotton-seed oil as the most fascinating of all the oils on account of the multiplicity of its sub-products. Mr. Pearson had dealt in detail with the by-products of the oil, and he (the speaker) had hung a diagram on the wall which showed a few of the more important products obtained from cotton seed, not only by the British method of crushing it whole, but also by the American method of decorticating the seed, extracting the kernel, and crushing the kernel only for oil. There were good and sufficient reasons, which it would take him too long to explain that afternoon, why the British manufacturers crushed their seed whole and did not follow the American method; it was not because they were behindhand in any way. Cotton seed could be roughly divided into two classes, the woolly and the bald varieties. The former comprised 95 per cent. of the seed produced per annum, so that the latter could, for the purposes of his remarks to-day, be neglected. Nearly all the woolly varieties were grown from upland American stock. The seed was first ginned, and then went through a second ginning process in what was called a saw linter, in which some of the longer residual cotton fibres were taken off and formed linters, from which various things were made. By using a recently-invented defibrating machine it had become possible to carry the removal of those residual fibres further, until the physical condition of the seed approximated to that of the bald seed, the material removed being termed "seed-lint." The British seed-crusher obtained

two products, oil and cake. The American produced three, namely, oil, hulls (the remains of the seeds after the kernels had been taken out) and decorticated cake (the remains of the kernel after expression of the oil). From the decorticated cake a flour was prepared in the United States containing about five times as much protein and fat as wheat flour and being practically starch-free. This cotton-seed flour constituted a valuable diluent for wheat flour. The little rolls exhibited were made from a mixture of about 6 per cent. cotton-seed flour and about 95 per cent. wheat flour. The "hulls" were now separated into their component parts of hull-fibre and shell-bran by a machine which had been introduced commercially only about two years before the war. The shell-bran formed the basis of the manufacture of many kinds of mixed food for cattle in the United States. "Linters," "seed-lint," and "hull-fibre" were all different grades or qualities of the residual fibre retained by the woolly cotton seed, and were all useful for the production of cellulose, which was the basis of a number of industries, such as the manufacture of paper, explosives, artificial silk, absorbent cotton, etc., etc. Mr. Pearson had very rightly pointed out in his paper that until recently the British seed-crusher was concerned mainly with the production of cake, and therefore his desideratum was a raw material, whether seed or nut, which contained not too large a proportion of oil. On the other hand, firms on the Continent for some years before the war had gone ahead with the manufacture of edible oils, and therefore sought out raw materials which gave a high percentage of oil. The war, among the many other changes which it had effected, had entirely revolutionised the ideas of British crushers with regard to the primary product of their plants, and they now used the richer oil-bearing seeds to an increasing extent, and would probably continue to do so. That change, however, would not put cotton seed in the background. Cotton seed was the inevitable concomitant of cotton cultivation. Professor Todd, one of the best known authorities on cotton, had said that a cumulative annual increase of from 800,000 tons to 1,000,000 bales of cotton was required to satisfy the world's requirements, so that they could look forward to a cumulative increase in the production of cotton seed. By the aid of the seed-defibrating machine which removed the short fibres without injury either to the fibres or to the seed, all varieties of woolly cotton seed were improved in value for the British crusher, and many varieties of cotton seed which were so heavily fibred as to be unsuitable for treatment in most British oil mills, could by defibration be converted into good merchantable seed. This, coupled with the successful application in industry of the residual fibres, put a different complexion upon the commercial value of the woolly varieties of cotton seed, which, by the exercise of proper care in selection, storing and shipping, might become a not unimportant factor in Imperial economics.

Mr. D. T. Chadwick (Indian Trade Commissioner) said that from the Indian point of view the most important point in the paper was the stress that was laid upon the fact that the British manufacturer was primarily a maker of cattle cake and not of oil. One result of that was that the Indian producer had to find a market for his richer oil seeds on the Continent, particularly in Germany and France; England neither wanted them nor bought them. He questioned Mr. Segundo's statement that cotton-seed oil was superior to all others for the production of margarine; ground-nut oils, coconut oil, and palm-kernel oil, must not be forgotten in that connection. He believed that in the original charter of the Tallow Chandlers' Company in the City of London the company were authorised to seize and destroy all adulterated oils. That was rather interesting in view of what Mr. Pearson had said about the measures that had been taken of late years to ensure the purity of the products of seed-crushing.

Dr. J. A. Voelcker said that while quite agreeing with Mr. de Segundo that a new era had come in the matter of crushing cotton seed, he should like to point out that the change had not been for the benefit of the British farmer. Whereas in the old days the farmer used to get genuine decorticated cake that had something like 16 per cent. of oil and perhaps 3 per cent. of husk, he now got a cake which was no better than the undecorticated variety, and which contained only about 5 per cent. of oil and something like 19 per cent. of undesirable fibre. Mr. Pearson had given a most interesting account of the improvements in the manufacture of oil, but while that was good in one direction it was not in another. It was good for the trade and the people who wanted the oil, but not for the farmer, because he got less oil left in his cake, and the better the pressing the worse the cake, although he had to pay as much for it as before. It was not quite true to say that no oil seeds were grown in England; especially since the war the growing of linseed—chiefly for the use of cattle—had been encouraged by the Board of Agriculture, and in Ireland considerable quantities were grown. Mustard seed was also largely grown in the eastern counties. He also could not agree that in the past the trade had been largely conducted for the benefit of the farmer; his experience was that oil was the chief consideration; the cake was considered as refuse, and the price the farmer had to pay for it largely depended on the price the crushers were getting for their oil. The war had brought home clearly the dependence of British people on fat being supplied to them in some form or other, and what was true for men was also true for cattle. All analytical chemists recognised the difference in the value of the oil and albuminoids according to the source from which they came, but the oil crushers and cake makers did not always recognise that. When dealing with linseed cake or cotton cake it was easy to say that

it was quite pure; but in a compound cake which was sold as containing so much oil and so much albuminoids, the oil might come from a variety of different sources, and it was necessary to pay particular attention to the sources from which the constituents were derived. He regretted the way in which cake manufacturers pushed their compound cakes; in his view they were merely devices to save the farmer trouble. If farmers made a scientific study of cattle-feeding, as they did in Germany, they could themselves do what the manufacturers were now doing for them. It was more important to know how the cakes were made up than to know that they contained so much oil, which might come from a very inferior source; but the makers still continued to guarantee the amount of oil content without any reference to the source from which it came.

Mr. H. J. Pooley said that although chemical extraction had been having rather a bad time lately, it was undoubtedly a coming process. He was sorry Mr. Pearson had not dwelt a little longer on extraction, and given them the benefit of his knowledge of some of its uses. For instance, it was very valuable in dealing with those materials the residue of which could not be used for cattle food, and for dealing with wood oils and those materials which could not be separated from the husk in a form which would enable them to be dealt with in the ordinary way. Extraction enabled all the oil to be got from materials of that kind. On the question of cost, Mr. Pearson said that the extraction process cost 50 per cent. more; but his own experience was that there was a difference in cost in favour of the extraction process of 2*s.* 6*d.* a ton.

Mr. J. E. Taylor, referring to the therapeutic value of cotton-seed flour, said that in the treatment of diabetes, chronic rheumatism, and in all cases where the uric acid diathesis was indicated, cotton-seed flour was undoubtedly beneficial, firstly on account of its proteid content. The proteid and fat content of cotton-seed flour was 60 per cent., and the carbo-hydrate content nil, which was a considerable advantage. Medical opinion differed as to whether it was advisable to give a preponderance of proteid matter in diet; but by using cotton-seed flour as an adjunct to ordinary flour the proteid was increased and the proportion of carbo-hydrates decreased, and consequently an admirable article of diet was secured. Cotton-seed flour was also very valuable both during and after the period of lactation; at least one well-known preparation on the market which had an extraordinary sale contained about 75 per cent. of cotton-seed flour. Cotton-seed meal, which was a cruder form, was equally valuable as a cattle food, and a friend of his who had experimented with it on British Friesian cattle had found that it increased their milk production by 10 per cent. Considerable quantities of that meal were used in Holland for that purpose, and it was interesting to know that the milk production in Holland was considerably greater per animal than was the case in this country.

Mr. F. J. Lloyd said he was consulting chemist to the British Dairy Farmers' Association, and dairy farmers were more interested in the cattle cakes produced in Great Britain than anyone else. He wished to warn cake-makers against a tendency which might prove very detrimental to the industry. When extracted meal was first introduced in Great Britain it was not successful, and after a time it was discovered that it was due to the fact that animals could not absorb the nitrogenous constituents of their food unless it also contained a fair amount of fat. No substitute for oats would ever be of value unless it contained as large a proportion of fat as was contained in oats. Linseed cake was especially valuable for two reasons; it contained more oil than most cakes, and was not hard. The tendency nowadays was to increase the amount of albuminoids and decrease the amount of oil in the cake, with the result that the albuminoids were wasted and not absorbed by the animal's body. Another tendency was to make the cake too hard, so that the animal could not digest it. The cake industry, if it wanted to succeed, must pay great attention to those two points, and produce a soft cake containing a large percentage of oil.

The Chairman (Lord Lamington) said he wished to express his gratitude to Mr. Pearson for having given them so very interesting a paper. What had impressed him most was the fact that the manufacturers were constantly on the alert to develop their industry and to find new processes. The British Oil and Cake Mills, Limited, of which Mr. Pearson was the head, did yeoman service during the war by building a number of different mills at the request of the Government for various processes—the extraction of glycerine and so on. He wished to thank Mr. Pearson very much indeed for his paper, and to congratulate him heartily.

Lord Lamington then left the meeting, the chair being taken by Dr. J. A. Voelcker.

Mr. A. W. MacIlwaine said he had been extracting oil for the last thirty-seven years by the so-called "chemical" process, which was really the physical process of dissolving out. He discovered about twenty-five years ago that the effect of the steam in the second part of the process was to destroy the poisonous ingredients in nearly all seeds. Mr. Pooley had said that castor residue was not fit for cattle food, but after it had been treated by steam he had found that was not the case. There was a great deal of prejudice amongst farmers against castor meal, so that he had not put it on to the market until the war began. Since then his firm had delivered between 1,000 and

2,000 tons for feeding purposes without there being a single instance of its having disagreed with the cattle. They claimed to have introduced a new cattle food which would be very valuable. Mr. Pearson had not mentioned the reason why in this country we had been behind the Germans before the war in the manufacture of edible oils. The main reason of that was because there was an import duty of £10 a ton on palm-kernel and other edible oils going into Germany. That enabled the Germans to over-bid this country in the purchase of raw materials on the West Coast of Africa. The war had changed that, and if German competition were re-introduced on similar lines he hoped a countervailing tax would be put on raw materials leaving the West Coast of Africa for Germany, in order to balance the German duty.

Mr. Walter F. Reid said the production of oil seeds in a scientific way so as to get the maximum amount of oil from a given area of land was a very important point. If farmers in England could develop that particular branch of agriculture larger quantities of oil might be grown in the country.

Replying to the discussion, Mr. Pearson said the reason English soap manufacturers had not made greater use of the rich seeds grown in India and elsewhere (a point to which Mr. Chadwick had drawn attention) was because in the past their plants had been designed to deal with those seeds which were least rich in oil, as they had regarded cake as their principal product. Now they had erected plant for dealing with the richer seeds he hoped they would be able to utilise the resources of the Indian Empire in those rich seeds to a greater extent. Referring to Dr. Voelcker's remarks on the subject of decorticated cake, he thoroughly sympathised with that gentleman. Owing to the form of contract adopted not being sufficiently rigid, a practice had grown up of mixing a little of the ground shell back again amongst the cake, with the result that the product on the market nowadays was really only semi-decorticated. With regard to the growing of oil seeds in England, the production in tons per annum did not run into more than five figures, which, compared with the enormous world production was insignificant. Dr. Voelcker's society had been the first to take steps to improve the quality of cakes, and in 1903 his (the speaker's) firm had adopted the practice of putting a label on their products certifying them to be pure within the terms of the guarantee recommended by the Royal Agricultural Society of England. As one of the leading manufacturers of those products in the country, he thought that guarantee was worth all the analyses put together. Although his firm were very large producers of compound cakes, he felt bound to endorse Dr. Voelcker's view that where a farmer had facilities for doing so it was to his advantage to buy "straight" cakes and mix them himself; but for small farms he thought there was much to be said for the compound cake. Mention had been made of the extraction process. It was undoubtedly of considerable value in dealing with those seeds the residue of which was of little value for feeding purposes; but for other seeds it was not very suitable, as it was important that a reasonable quantity of oil should be left in the residue for cattle feeding. He did not think, therefore, it would ever be used for linseed and cotton seeds and ground-nuts. With regard to the cost of the process, he had found that to be considerably more than 50 per cent. above that of the ordinary method of crushing. The difference between his figures and those of Mr. Pooley was probably due to the use of different methods of compilation. When the enormous extra cost in coal consumption, the loss of solvent, and other things, were considered, although there might be a saving in labour, it was evident that the aggregate cost of the extraction process must be considerably higher. He agreed with Mr. MacIlwaine that the fiscal systems of Continental countries had been largely responsible for the expansion of their edible oil trade.

A hearty vote of thanks having been accorded to Mr. Pearson, the meeting terminated.

GENERAL NOTE.

Science and Industry.—Signs are not wanting that the value of science to industry is becoming more widely recognised by employers, and numerous firms have made arrangements for the scientific instruction of their employees. A new departure in this direction has been inaugurated by the Anglo-Mexican Petroleum Company, who have arranged for the delivery of ten lectures to the staff by Mr. C. R. Darling, Lecturer in Physics, Finsbury Technical College, on the commercial applications of Physics. These lectures are intended to form a groundwork for specialised lectures to be given by experts connected with the Company, and to furnish a broad outlook on the subject of the application of science to industry. A lecture-room has been provided on the Company's premises at 16, Finsbury Circus, E.C., furnished with the necessary fittings for experimental demonstrations. The provision of a connected course of lectures of this kind is a novel feature, and should prove a valuable aid to any scheme of commercial scientific education.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday afternoon, at 4.30 p.m. :—

December 17. — Constantine Grunwald, late Chief of Intelligence Department, Russian Ministry of Trade and Industry, "The Present

Economic Position of Russia, and some Aspects of its Future Development."

INDIAN SECTION.

At 4.30 p.m.

THURSDAY, DECEMBER 18.—P. J. HARTOG, C.I.E., M.A., Member of the Calcutta University Commission, 1917–1919, "Some Problems of Indian Education." The Right Hon. LORD MESTON, K.C.S.I., LL.D., will preside.

FRIDAY, JANUARY 2.—A. P. MORRIS, B.Sc., A.M.Inst.C.E., Provincial Art Officer, Burma, "Burmese Village Industries: their Present State and Possible Development." SIR HARVEY ADAMSON, K.C.S.I., M.A., LL.D., Lieutenant-Governor of Burma 1910–15, will preside.

Papers to be read after Christmas:—

AIR-COMMODORE EDWARD MAITLAND, C.M.G., D.S.O., "The Commercial Future of Airships."

SIDNEY PRESTON, C.I.E., "English Canals and Inland Waterways."

BRIGADIER-GENERAL SIR HENRY P. MAYBURY, K.C.M.G., C.B., M.Inst.C.E., "Road Transport."

CHARLES H. SHERRILL, "Stained Glass."

ALFRED E. HAYES, General Secretary, English Language Union, "The English Language and International Trade."

JAMES CURRIE, C.M.G., Ministry of Labour (Training Department), late Principal, Gordon Memorial College, Khartoum, "Industrial Training."

LADY INGLEFIELD, President, Buckinghamshire Lace Association (North Bucks and Bedfordshire), "The Hand-made Lace Industry."

WILLIAM JAMES GARNETT, First Secretary, H.B.M. Diplomatic Service, "Mongolia from the Commercial Point of View."

GRAILY HEWITT, "Rolls of Honour."

ALFRED H. POWELL, "Ancient Cottages and Modern Requirements." The Right Hon. EARL FERRERS will preside.

CHARLES CROWTHER, "The Arts and Crafts of Japan" (with examples from the author's private collection).

SIR CECIL HERTSLET, late H.M.B. Consul-General for Belgium, "The Ruin and Restoration of Belgium." EMILE CAMMAERTS will preside.

WILLIAM CRAMP, D.Sc., M.I.E.E., "Pneumatic Convoying Plants, with special reference to the Transport of Grain."

L. GASTER, "Industrial Lighting in its relation to Efficiency."

H. M. THORNTON, "Gas in relation to Industry and Housing."

LIEUT.-COMMANDER NORMAN WILKINSON, R.N.V.R., O.B.E., R.O.I., R.I., "Naval Camouflage."

BRIGADIER-GENERAL LORD MONTAGU OF BEAULIEU, C.S.I., "Roads and Transport in India."

SIR GEORGE CUNNINGHAM BUCHANAN, K.C.I.E., M.Inst.C.E., "The Ports of India: their Administration and Development."

SIR JOHN HUBERT MARSHALL, C.I.E., M.A., Litt.D., F.S.A., Director-General of Archæology in India, "Recent Archæological Discoveries in India."

SIR VALENTINE CHIROL, "The Enduring Power of Hinduism." (Sir George Birdwood Memorial Lecture.)

SIR FRANCIS WATTS, K.C.M.G., D.Sc., Imperial Commissioner of Agriculture for the West Indies, "Tropical Departments of Agriculture, with special reference to the West Indies." LIEUT.-COLONEL SIR DAVID PRAIN, C.M.G., C.I.E., LL.D., F.R.S., Director of the Royal Botanic Gardens, Kew, will preside.

INDIAN SECTION.

At 4.30 p.m.

January 2, February 19, March 18, April 15, May 20.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 p.m.:—

February 3, March 2, May 4.

CANTOR LECTURES.

Monday evenings, at 8 p.m.:—

JOHN THEODORE HEWITT, M.A., D.Sc., Ph.D., F.R.S., Emeritus Professor of Chemistry, East London College, "Synthetic Drugs." Three Lectures.

Syllabus.

LECTURE III. — DECEMBER 15. — Modified alkaloids, *e.g.* heroin, euquinine—Organic compounds of arsenic (atoxyl, salvarsan), antimony, mercury and other metals—Conclusion.

CAPTAIN H. HAMSHAW THOMAS, M.B.E., M.A., F.G.S., Fellow of Downing College, Cambridge, and formerly of the Royal Air Force, "Aircraft Photography in War and Peace." Three Lectures.

January 19, 26, February 2.

CHARLES FREDERICK CROSS, B.Sc., F.R.S., F.C.S., "Recent Research in Cellulose Industry." Three Lectures.

February 16, 23, March 1.

WALTER ROSENHAIN, B.A., D.Sc., F.R.S., Superintendent, Department of Metallurgy and Metallurgical Chemistry, National Physical Laboratory, "Aluminium and its Alloys." Three Lectures.

April 12, 19, 26.

ARTHUR THOMAS BOLTON, F.R.I.B.A., F.S.A., Curator, Soane Museum, "The Decoration and Architecture of Robert Adam and Sir John Soane, 1758–1837." Three Lectures.

May 3, 10, 17.

JUVENILE LECTURES.

Wednesday afternoons, at 3 p.m.:—

LOUGHNAN PENDRED, M.I.Mech.E., Editor of *The Engineer*, "Railways and Engines."

January 7, 14.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, DECEMBER 15...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Professor J. T. Hewitt, "Synthetic Drugs." (Lecture III.)

Faraday Society, at the Chemical Society, Burlington House, W., 7.30 p.m. Annual General Meeting. 8 p.m. 1. Lieut. W. A. Macfadyen, "Electrolytic Iron Deposition." 2. Mr. A. G. Tarrant, "The Measurement of Physical Properties at High Temperatures." 3. Mr. J. G. Williams, "The Electrolytic Formation of Perchlorate from Chlorate." 4. Professor A. W. Porter, "On the Vapour Pressures of Binary Mixtures." 5. Mr. Shinkichi Horiba, "Some Relations between the Solubilities of Solutes and their Molecular Volumes." 6. Dr. E. J. Hartung, (a) "An Accurate Method for the Determination of Vapour Pressure"; (b) "Some Properties of Copper Ferrocyanide." 7. Professor E. D. Campbell, "The Solution Theory of Steel and the Influence of Changes in Carbide Concentration on the Electrical Resistivity."

East India Association, 7A, Tothill-street, S.W., 3.45 p.m. Lieut.-Col. J. Shakespear, "Reflections on the Government of Wild Tribes on the North-Eastern Frontier of India."

Surveyors' Institution, 12, Great George-street, S.W., 8 p.m. Discussion on the President's Address on "The Future of the Institution."

Geographical Society, 135, New Bond-street, W., 8.30 p.m. Captain E. H. Keeling, "In Northern Anatolia, 1917."

Electrical Engineers, Institution of, at the Chartered Institute of Patent Agents, Staple Inn-buildings, Holborn, W.C., 7 p.m. Mr. R. Rankin, "Some Reflections on Labour."

TUESDAY, DECEMBER 16...Petroleum Technologists, Institution of, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5.30 p.m. Mr. A. J. Wilson, "The Application of Liquid Fuel to Heavy Oil Engines."

Illuminating Engineering Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Captain W. A. Howells, "The Art of Camouflage."

Electrical Engineers, Institution of (North-Western Centre), 17, Albert-square, Manchester, 7 p.m. Mr. J. M. Scott-Maxwell, "Scientific Works Management."

Civil Engineers, Institution of, Great George-street, S.W., 5.30 p.m. Major E. O. Henrici, "Precise Levelling."

Statistical Society, Adelphi Terrace, W.C., 5.15 p.m. Mr. J. E. Allen, "Some Changes in the Distribution of the National Income during the War."

British Decorators, Institute of, Painters' Hall, Little Trinity-lane, E.C., 7.30 p.m. Mr. G. Giles, "Kitchens and Bath-rooms."

Photographic Society, 35, Russell-square, W.C., 7 p.m. Paper by Mr. N. E. Luboshez.

Colonial Institute, Central Hall, Westminster, S.W., 3.30 p.m. Professor C. A. Middleton Smith, "The British in the Far East."

Physical Society, Imperial College of Science, South Kensington, S.W., 2 p.m. Annual Exhibition.

Industrial League and Council, Council Chamber, Guildhall, E.C., 4.30 p.m. Lord Emmott, "Government Control and Industry."

WEDNESDAY, DECEMBER 17.—ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Mr. C. Grunwald, "The Present Economic Position of Russia, and Some Aspects of its Future Development."

Central Asian Society, at the Royal Society, Burlington House, W., 4.30 p.m. Mr. M. Funduklian, "Armenia."

Electrical Engineers, Institution of (Wireless Section), at the Institution of Civil Engineers, Great George-street, S.W., 6 p.m. Professor G. W. O. Howe, "High Frequency Resistance of Wires and Coils."

(South Midland Section.) The University, Birmingham, 7 p.m. Mr. J. M. Scott-Maxwell, "Scientific Works Management."

Meteorological Society, 70, Victoria-street, S.W., 5 p.m. 1. Mr. F. J. W. Whipple, "The Laws of Approach to the Geostrophic Wind." 2. Mr. G. M. B. Dobson, "Winds and Temperature Gradients in the Stratosphere." 3. Captain C. J. P. Cave, "Quotations from the Diary of Samuel Pepys on the Weather."

Geological Society, Burlington House, W., 5.30 p.m. 1. The Secretary of State for the Colonies' "Description of an Earthquake at Rabaul in May, 1919." 2. Mr. R. R. Lempriere, "The Raised Beach at South Hill (Jersey)." 3. Professor S. J. Shand, "A Rift-Valley in Western Persia."

United Service Institution, Whitehall, S.W., 3 p.m. Major-General Sir Lewis Jackson, "Possibilities of the Next War."

Oriental Studies, School of, Finsbury-circus, E.C., 5 p.m. Mr. L. Binyon, "The Art of Asia. Lecture V.—Japanese Art."

Public Health, Royal Institute of, 37, Russell-square, W.C., 4 p.m. Dr. I. C. Gibbon, "Housing and the Slum Problem."

THURSDAY, DECEMBER 18...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Indian Section.) Mr. J. P. Hartog, "Some Problems of Indian Education."

Electrical Engineers, Institution of, at the Institution of Civil Engineers, Great George-street, S.W., 6 p.m. Messrs. D. M. W. Hutchison and W. J. Wayte, "Electricity in Tin Mining."

(Irish Centre.) Royal College of Science, Dublin, 7 p.m. Mr. T. C. Roberts, "Water Power."

Royal Society, Burlington House, W., 4.30 p.m.

Chemical Society, Burlington House, W., 8 p.m. Professor J. Walker, "War Experiences in the Manufacture of Nitric Acid and the Recovery of Nitrous Fumes."

Mining and Metallurgy, Institution of, at the Geological Society, Burlington House, W., 5.30 p.m. Discussion on Mr. H. L. Sulman's paper, "A Contribution to the Study of Flotation."

Concrete Institute, 296, Vauxhall Bridge-road, S.W., 7.30 p.m. Mr. M. S. R. Adams, "The Use of Elliptical Vaulting as a Primary Factor in Contemporary Architecture."

Architects, Society of, 28, Bedford-square, W.C., 8 p.m. Professor H. Adams, "The Need for more Care in Warehouse Design."

FRIDAY, DECEMBER 19...Mechanical Engineers, Institution of, Storey's-gate, Westminster, S.W., 6 p.m. Mr. G. H. Burley, "The Cutting Power of Lathe Turning Tools." (Part II.)

Journal of the Royal Society of Arts.

No. 3,500. VOL. LXVIII.

FRIDAY, DECEMBER 19, 1919.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

CANTOR LECTURE.

Monday evening, December 15th; DR. JOHN THEODORE HEWITT, F.R.S., Emeritus Professor of Chemistry, East London College, delivered the third and final lecture of his course on "Synthetic Drugs."

On the motion of the Chairman, DR. M. O. FORSTER, F.R.S., a vote of thanks was accorded to Professor Hewitt for his interesting course.

The lectures will be published in subsequent numbers of the *Journal*.

FIFTH ORDINARY MEETING.

Wednesday, December 17th, 1919; SIR HENRY TRUEMAN WOOD, Chairman of the Council, in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Barnes, Jabez, J.P., Harrow.
Haigh, Bernard Parker, M.B.E., D.Sc., London.
Hammer, K. V., Christiania, Norway.
Horsnell, Daniel Thomas, M.I.Mech.E., M.I.Mar.E., London.
Howard, Henry Eliot, J.P., Stourport.
Jack, Robert Wilson, Girvan, N.B.
Kemp, Mrs. Mabel Amy, London.
Longstaff, Captain George William, R.A.F., London.
Mitchell, Harold F., London.
Mukharji, J., Srinagar, India.
Ogden, Alfred, Manchester.
Oldfield, Percy Jack, London.
Parsons, Robert Hodson, Assoc.M.Inst.C.E., Chingford.
Scott, James P., Birmingham.
Stuart, George Archibald Douglas, Bournemouth.
Tidswell, Mrs. Mary Florence, London.

The following candidates were balloted for and duly elected Fellows of the Society:—

Agar, Alfred, Belfast.
Barton, Alfred Danell, A.M.I.A.E., London.
Bishop, Edwin Kelsham, London.
Briggs, Roland Hunter, A.M.I.Mech.E., Harrow-on-the-Hill, Middlesex.
Britten, William Robert James, Horley, Surrey.
Brown, Alexander, Belfast.
Gill, Geoffrey M., London.
Gooby, Alfred H., London.
Hart, James Connorton, London.
Ide, H. W. F., London.
Longcroft, Cecil J., London.
Newnes, Sir Frank, Bt., London.
Pearson, John Westall, London.
Russell-Cotes, Sir Merton, J.P., Bournemouth.
Smout, Arthur John Griffiths, A.I.C., A.I.M.M., F.C.S., King's Heath, Birmingham.
Turrell, Frank William, King's Heath, Birmingham.

A paper on "The Present Economic Position of Russia, and some Aspects of its Future Development," was read by Mr. CONSTANTINE GRUNWALD, late Chief of Intelligence Department, Russian Ministry of Trade and Industry.

The paper and discussion will be published in a subsequent number of the *Journal*.

INDIAN SECTION.

Thursday afternoon, December 18th, 1919; The Right Hon. LORD MESTON, K.C.S.I., LL.D., in the chair. A paper on "Some Problems of Indian Education" was read by Mr. P. J. HARTOG, C.I.E., M.A., Member of the Calcutta University Commission.

The paper and discussion will be published in a subsequent number of the *Journal*.

JUVENILE LECTURES.

The usual short course of lectures adapted to a juvenile audience will be delivered on Wednesday afternoons, January 7th and 14th, 1920, at 3 p.m., by Mr. LOUGHNAN PENDRED, M.I.Mech.E., Editor of *The Engineer*, on "Railways and Engines." The lectures will be fully illustrated with working models and lantern-slides.

Special tickets are required for these lectures. They can be obtained on application to the Secretary.

A sufficient number of tickets to fill the room will be issued to Fellows in the order in which applications are received, and the issue will then be discontinued. Subject to these conditions, each Fellow is entitled to a ticket admitting two children and one adult. Fellows who desire tickets are requested to apply for them at once.

REPRINT OF CANTOR LECTURES.

The Cantor Lectures on "Coal and its Conservation," by WILLIAM ARTHUR BONE, D.Sc., Ph.D., F.R.S., Professor of Chemical Technology at the Imperial College of Science and Technology, have been reprinted from the *Journal*, and the pamphlet (price 1*s*. 6*d*.) can be obtained on application to the Secretary, Royal Society of Arts, John Street, Adelphi, W.C. (2)

A full list of the lectures which have been published separately, and are still on sale, can also be obtained on application.

BOOKS OF TICKETS.

Every Fellow is entitled to admit two friends to the Meetings of the Society (with the exception of the Juvenile Lectures, for which special tickets are necessary). Books of tickets for this purpose can be obtained on application to the Secretary.

LIST OF FELLOWS.

The new edition of the List of Fellows of the Society is now ready, and copies can be obtained on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

FOURTH ORDINARY MEETING.

Wednesday, December 10th, 1919; The Hon. SIR CHARLES ALGERNON PARSONS, K.C.B., LL.D., D.Sc., F.R.S., Vice-President of the Society, in the chair.

THE CHAIRMAN, in introducing the lecturer, said that the subject of the paper was one that the war had emphasised as being of the greatest importance. Coal, water-power, and oil were at present our chief sources of energy; when they were exhausted, what would be the future of the human race? Sir Oliver Lodge would, he hoped, tell them of some other sources of energy which might be utilised in the future.

The lecture delivered was—

TRUEMAN WOOD LECTURE.

SOURCES OF POWER KNOWN AND UNKNOWN.

By SIR OLIVER LODGE, D.Sc., Sc.D., LL.D., F.R.S.

All that the human race can do in the material world is to move matter. To this end our muscles are designed, and only with their aid can we operate. Moreover, it is really through our muscles that we primarily enter into relation with the material world. Our muscular sense has informed us of the existence of an external world; it is that sense which enables us to interpret the indications of other senses, and which clearly discriminates "matter" from what might have been sensory illusion. All our physical activities may be summed up as the movement of matter: indeed, even our bodies are so composed, and are what we move in the first instance. The mind is in a different category, and when we think or will or remember, or suffer or enjoy, we are not necessarily moving matter; though usually some brain process accompanies these mental operations; but when a poet or a musician tries to express or record his thoughts, he has no other means available than to move a pen over paper, or work a violin bow or a keyboard, or of course he may set in action the muscles of his throat, and generate vibration in the air in that way.

That the whole function of an engineer is to move matter is fairly obvious. Civil engineers, in a spirit of inverted pride, sometimes denote themselves as "dirt-shifters"; but the construction of a bridge, or of an engine, or of a dynamo, can also be described as the shifting and placing together of material objects. The farmer and gardener again, do nothing else. All real operations, from the production of electrical currents to the growth of seeds, are performed by Nature. Locomotion, in one form or another, is the business of man.

Every form of physical activity requires power; hence power or energy is the most pressing material need of man. Food and fuel obviously belong to the same class; for whether the power exerted be directly muscular or indirectly mechanical, makes no difference in principle. Yet there is a difference. Food is mainly used by an animal for developing energy before it has assumed the form of heat. Fuel, unfortunately, at the present time, has to produce heat first, so that the heat can be

employed in some form of heat engine. We are thus up against the conception of temperature, and the inexorable law of efficiency, $\frac{T-T^1}{T}$. Heat can only be used when it falls in temperature from a hotter body to a cooler, and it is liable readily to fall in temperature without being utilised. When that happens there is loss of efficiency, and consequent waste of available power. A flagrant instance of fall of temperature with nothing to show for it, is the drop of temperature between furnace and boiler. All the heat may be transmitted through the walls of a perfect boiler, but it has become heat at a much lower level. The subsequent drop of temperature from boiler to condenser is utilised to the utmost by a multitude of ingenious devices, from Newcomen and Watt down to Sir Charles Parsons, whose engines I suppose utilise this fall of temperature in the most direct possible manner. But if the temperature of combustion could be made use of, as in a frictionless flame turbine, more of the fuel energy could be utilised. Internal-combustion engines attempt this, no doubt successfully up to a point; but so long as they require cooling jackets, whereby heat falls in temperature without doing work, so long they are imperfect Utilisation of undesired local heat to generate high pressure steam, would seem likely to be a step in the right direction, and an engine with flame on one side of the piston and steam on the other has become known.

But animals do not turn their food energy into heat at all—save what is needed for warmth. Nor does a voltaic battery turn its chemical energy into heat. Any heat produced is waste: the chemical energy ought to go direct into an electric current; and an electric motor is capable of utilising current energy very efficiently. Unfortunately, the chemicals are expensive, and it pays better to conduct electrochemical operations by aid of a dynamo and expenditure of mechanical energy, than to obtain mechanical energy from electrochemical operations.

It is important to realise that the law of efficiency $\frac{T-T^1}{T}$ is only applicable when the terms "heat" and "temperature" are applicable. The second law of thermodynamics refers to heat only, and not to any other form of energy. It does not apply to moving objects directly harnessed—like a fly-wheel; nor would it apply to molecules if their motion could be directly utilised. Organised and systematic motion is not "heat." In so far as the sun is a hot body, the formula is applicable, but it is a body at so excessive a temperature that the efficiency is nearly perfect. The fall of temperature from earth to absolute zero is 300°, but the fall from sun to earth is about 6000°, hence the efficiency is $\frac{6000}{6300}$, or $\frac{20}{21}$, or very nearly unity. The leaves of trees, and vegetables generally, are able therefore to absorb and utilise solar energy in the refined chemical operations needed for the production of wood and coal, as well as of food, and they seem able to do this without much regard to any hampering law of efficiency.

This is undoubtedly the best way of utilising present solar energy; and the moral is—promote Agriculture of every kind, and in the widest sense. The solar rays which fall on the sea are not wasted; they are needed for wind and rain, and they give us all our water-power, but solar rays fallen on barren soil or hopeless jungle are a reflection on humanity: that kind of waste ought not to occur. The progress of bacteriological science might make every soil fertile; even rocks can be dynamited into something; and jungles and swamps should be cleared. We are not living in the carboniferous epoch, and we cannot wait millions of years for the contemporary production of coal.

But it is not food and fuel alone that we get from the present-day sunshine: we get wind and water-power, too; and it is economical to use them where we can. The beauty of a waterfall is enticing, but looked at with an engineering eye many waterfalls suggest a sad waste of power. And even when there is not a waterfall, so called, all water in descending from high-level lakes to the sea must be able to give out power, which might be used wherever it is convenient to harness it.

In other ways the present sunshine may be utilised. I cannot regard with hope the idea of merely converting it into low-temperature boiler-heat. The barrenness of the Sahara would be the only excuse for the extensive use of burning-glasses or mirrors, and it is, perhaps, the only kind of place where such an enterprise could rationally be contemplated. But then there are very few parts of the Sahara where power is particularly wanted. Economy of transmission has a limit.

[A digression on the energy of the past sun may be permitted. All that the earth has caught, for all the millions of years that it has existed, is the merest fraction of what the sun has radiated in the same time. The earth

to the sun is like a printer's full stop at a distance of ten feet from a halfpenny. Some of the radiation from a globe one inch in diameter falls on the spot $\frac{1}{100}$ in. in diameter ten feet away, but that little speck only catches the hundred and fifty millionth part of the whole. What has become of the rest of the solar energy? It must still be careering through space. The ether is perfectly transparent, and only when it encounters matter will the radiation be mopped up and turned into heat. Not our sun only, but all the millions of other suns, have likewise been always pouring out radiation into space. Is there any hope of catching and utilising it? I trow not. In spite of all this constant flood of energy, space is cold; very near absolute zero. The reservoir is so enormous that all these taps, running for ages, have made no impression on it, have not raised the level a perceptible amount.]

The only portion of the past solar energy available to us is that which was caught and stored by vegetation. This it is which has produced combustible matter; this it is, probably, which has also liberated free oxygen into the air.

The amount of atmospheric oxygen, and the amount of combustible matter in the earth's crust, were believed by Lord Kelvin to correspond; one was the chemical equivalent of the other; they had been separated by solar radiation. If so, the amount of combustible matter, of every vegetable kind, in the earth's crust can be estimated; for it is easy to estimate the amount of oxygen in the air.

The amount of combustible matter is limited, but the oxygen of the atmosphere is also limited. We have not exhausted the total fuel supply as yet, and it is to be hoped that we never shall attempt it. It would be poor progress if the human race, in pursuit of mechanical activity, were to burn up the air it breathes. There is plenty left at present, but no thanks to human beings or animals that it is so. All our factories burn it up. Only vegetation restores and renews it. We used to burn up the air of our rooms in order to light them; we do better than that now. The utilisation of chemical or molecular energy seems necessarily limited. A great consumption of material yields comparatively little power. More plentiful and cleaner power is wanted. Some other source of energy ought to be discovered before the human race is a century older.

Are there any sources of energy not derived from the sun? Yes, two. The internal heat of the earth and the tides. Internal heat of some kind, whether due to radioactivity or otherwise, makes itself manifest in the neighbourhood of hot springs and volcanoes. The eminent Italian engineer Signor Luiggi Luigi has shown us how to bore into the bowels of Vesuvius and extract from it some of its energy in a practical manner. A remarkably interesting achievement!

The utilisation of the tides is continually being pressed by amateurs, but engineers rather take their stand with Lord Kelvin in recognising the extreme slowness of tidal operation. They realise the vast reservoir that would have to be filled and emptied every twelve hours, and how likely it is that the reclaimed land of the reservoirs would be of more value than the power; at least in any locality where the power was really wanted, without prohibitive distance of transmission.

The power of waves is different. That does come from the sun, and it is not leisurely like the tides. Those who have watched Atlantic rollers booming into creeks on the west coast of Ireland have felt that here surely was available power. We may imagine a Dreadnought (now let us hope of no further use) attached by a long girder to rack-work machinery, and being hoisted up and down by the waves. The weight that could thus be hoisted might be far greater than a Dreadnought—the whole German fleet for instance might be attached to the lever; it would give a good many foot-tons per minute; but whether any machinery would stand the strain I do not know. The idea is probably absurd, but it seems to me less problematical than the tides. Besides, in large harbours the tides are wanted for scouring purposes, and for clearing away a bar.

Is there any concealed store of energy recently discovered and not yet utilised? There is indeed. There are two,—one certain, the other rather hypothetical: the energy of the Atom, and the energy of the Ether. I propose to say nothing about etheric energy. If it exists, as I think it does, it is enormous, exceeding the bounds of imagination; but at present it is utterly beyond our reach. Atomic energy is rather inaccessible too, but not hopelessly so. It is far less in amount than etherial energy, but it is immense compared with any form of chemical or molecular energy, such as that derived from combustion or explosives.

By atomic energy I mean the constitutional

energy of an atom—the energy which makes it what it is. If this energy is given up in any considerable degree, the substance ceases to be what it was, and becomes a substance lower down in the scale. Utilisation of atomic energy would involve the stepping down, the degradation, of matter. The term is purely technical—it has been already applied to energy without moral stigma. All it means is that heavy atoms may become lighter atoms, and in so doing must give off a definite proportion of their great store of energy.

This spontaneously happens in the phenomenon known as radio-activity. If it had not spontaneously happened, we should have known nothing about the energy concealed in an atom. The explosive or radio-active atom has given the secret away. All atoms possess energy, but some cannot hold it all. These are the radio-active elements, and they periodically fire off projectiles with more than volcanic violence. A radium atom firing off a particle, which turns out to be a positively charged atom of helium, is like a two-ton gun firing a hundred-pound shot. That is about the actual proportion between the projectile and the rest of the atom; which naturally recoils each time it fires. The recoil has been observed. Before it has exhausted its ammunition it fires off five such projectiles, and then settles down into a quieter existence as lead—or, if not exactly lead, something chemically indistinguishable from lead. A uranium atom had already fired off four projectiles in order to become radium. Radium is a temporary half-way house between uranium and lead: it is active, but not so fiercely active as some of the intermediate substances, which last so short a time that they barely have names. They destroy themselves by their own activity, and consequently are very scarce—like a population with a high death-rate. Radium is of moderate activity; its lifetime is of the order a thousand years, whereas the lifetime of some of the intermediate substances may be measured in weeks or even minutes. Yet they are real elements, with a place in the series, and they have definite spectra and chemical properties.

Do not suppose that the well-known radium is an exceptional substance. It would seem that all substances of very high atomic weight are liable to behave in this way—it is only a question of degree. And it is not by any means their whole energy that they thus exhibit, it is the energy they expend and get rid of—their waste energy—which we perceive. And when we speak of their explosion, it is to be noted that the explosion is not a shattering or bursting of the gun, it is merely the firing of a shot; except that in the atomic case the shot was part of the gun. The energy retained is far more than the energy expended. And when its active transformations have ceased and left it in a stable state, like lead or gold or silver or copper or iron, or any common element, we are not to suppose that because it is quiescent therefore it has no store of internal energy. Appearances are deceptive. Anyone looking at cordite might think it harmless enough; and so it is till a suitable stimulus is applied. It does not go off spontaneously, or at least it is not wanted to. Gunpowder and any other explosive exhibits no trace of its secret to mere inspection; nor do the atoms of ordinary matter show that they are fearfully energetic; but the energy is there.

We may now go on to ask: What corresponds to the gunpowder, when I speak of a gun firing a shot? What propels the projectile? It is a very proper question, but at present it can only be partially answered.

There are two kinds of projectiles fired off by a substance—the heavy shot or α ray, which is known to be a helium atom, and the lighter shot or β ray, which is the fundamental unit of electricity, the negatively charged unit particle—an electron. Several electrons may be expelled, and they will not make much difference to the weight of substance left behind, but they will have left it positively charged; and in that case it is liable to fling away one of its massive positively charged particles, too. One event follows the other, and whether the electron always escapes first is uncertain. Whichever event procedes, in different cases, the other is likely to follow.

Many circumstances can stimulate the escape of an electron; not, indeed, of the deeper-seated constitutional electrons, but of the outlying superficial charges which are responsible for chemical affinity. Mere friction removes some of them, and leaves the substance positively charged. The removed electrons will have gone to the rubbing substance, and will have charged it negatively. Splashing of water, chemical action in innumerable forms, effects the transfer of electrons, and consequent charging of bodies. Ultra-violet light falling upon clear metal, and indeed upon a large variety of substances, causes electrons to be expelled, until the surface is positively charged enough to hold them back. The discharge will go on continuously if more are supplied from a battery. The jostling of the

molecules by heat will often cause electrons to escape, but not usually until a temperature of red or white heat is reached. Singularly enough, a comparatively low temperature will emit a few positive particles for a time; but this emanation soon ceases, the material gets tired as it were, and has to be re-born or renewed somehow, if the process is to be continued. Not so with the negative emission from hot bodies. This will go on as long as fresh particles are supplied.

In many ways, therefore, we can stimulate the escape of stray electrons, and it appears that by the aid of X-rays, or of projectiles from other atoms, we are beginning to learn how to disturb effectually, and even to eject, the deep-seated constitutional variety; though usually others immediately take the place of the ejected one, with consequent radiation of definite type. If a pair of β particles were permanently extruded, an α ray would probably follow, in order to restore the neutrality of the atom; and the atom would have gone a step down in the scale. This happens spontaneously, but the result of experience is that we cannot bring about the catastrophe by ordinary means. We cannot alter the spontaneous rate, by anything we as yet know how to do. Heating and cooling—alterations of molecular movement—seem impotent to get down to the inner mechanism. Still, we are certain that that inner mechanism is a most energetic system; and just as the internal charges are equally positive and negative, so I believe atomic energy is both static and kinetic—though perhaps not equally so.

The modern view of an atom is a central positive nucleus like a sun, and a revolving system of negative electrons like planets. The electric planetoids, so near this "sun," and subject to its powerful electrical attraction, must be revolving with prodigious speed, and with a frequency of orbital revolution exceeding in most instances even the frequency of light—a frequency only attained in general by the ultra-rapid X-rays. Accordingly, these little bodies have plenty of kinetic energy, and when they escape as β rays, they do so with something like the velocity of light.

The *frequencies* possible in a hydrogen atom turn out, in Bohr's theory, to be of the order 10^{16}, being either 10^{16} itself or else $\frac{1}{8}$ of 10^{16}, or $\frac{1}{27}$ of 10^{16}, the denominators being the natural cubes. For heavier kinds of atoms, this frequency must be multiplied by the square of the number allotted to the element in Mendelejeff's series.

The *diameters* of the orbits will be of the order 10^{-8} cm. divided by the atomic number and multiplied by the successive square numbers, 1, 4, 9, etc.

The *velocities* will be of the order 10^{8} cm. per second multiplied by the atomic number and divided by the natural numbers, 1, 2, 3, etc.

So for the heavy atoms, whose atomic number is approaching a century, the inner electron speeds are getting near to the velocity of light; hence probably their instability.

The positively charged nucleus is in different case. Its energy is more likely to be static, *i.e.* potential, like things held or caught together, as a detent may hold a strong spring. Let them be liberated, and they fly with great violence, presumably under electrical repulsion: the potential gradient near the nucleus is enormous, and the speed therefore very great, so that each atom where it strikes a zinc sulphide target makes a luminous splash. Taking the size of the nucleus as comparable to 10^{-12} cm., the acceleration of an α particle is Ne^2/Kmr^2 m being the mass of a helium atom; and this equals $3 \times 10^{26}N$ centimetres per second, at the start, and must be reduced to near zero at the confines of the atom. (N is thea tomic number.)

The projection of an α particle is therefore literally an explosion, and the force can very quickly get up an enormous speed. (The acceleration of a bullet in a rifle is comparable to 10^{7} or 10^{8} of the same units, at most.) The speed with which an α particle is ejected is about one-fifteenth that of light—sufficient to carry it to New York, if there were no obstruction, in a quarter of a second. Its energy is therefore, weight for weight, a million times that of a bullet. Only because an atom is so small does it fail to do any damage.

But the number of projectiles from a milligramme of radium is about thirty million a second; hence, in the aggregate, they generate a very perceptible amount of heat. We may not know the exact cause of their retention, or of their propulsion, but no one can deny that the energy is there. The main difficulty is to understand how they are retained and packed together into the exceedingly minute nucleus. The natural suggestion is that the cement consists of interleaved or interlocked negative electrons; and when these are dislodged by some perturbation from the orbital part of the atom, or by the impact of a projectile, the liberated positive particles are driven asunder.

As to the atoms' orbital electron energy, that is probably kinetic, they probably escape

with the velocity with which they were revolving in their orbits before perturbation. This is rendered plausible by the fact that their emission depends on synchronism between the periods of the particles and the X-ray disturbance which ejects them. Their energy of ejection is found to depend on the frequency of the radiation which stimulates it; a fact which at once suggests a storing of received synchronous vibrations, till a quantum of energy sufficient for ejection has been accumulated. Moreover, spectrum analysis of the derived or secondary X-rays, emitted by a substance exposed to radio-active bombardment, is also a test of the frequency of orbital revolution.

Particles can be ejected from one of several orbits—called respectively K or L or M, the K orbit being the nearest to the nucleus and therefore of highest frequency. Electrons are ejected at speeds still greater than α particles, and occasionally approach to within a few per cent. of the speed of light.

If we calculate the amount of energy thus quietly existing in the atoms of any visible piece of matter, we shall find it enormous. If each atom is the seat of these high velocities, and equivalent high explosive forces, the aggregate of energy in a few trillion atoms is very great; and it takes fully a trillion atoms to make a perceptible speck of matter.

To illustrate the energy possible in any reasonably small quantity of substance, it is sufficient to reckon the energy in a couple of grammes, or say thirty grains, of matter moving at one-tenth the speed of light. It need not be moving in the sense of locomotion; internal motion of its parts does just as well; and static energy can be equally well included, since its liberation will produce these high velocities. The energy is 10^{19} cgs. units or ergs. Now a foot-ton is 3×10^{10} ergs. Hence the energy of a few grammes of matter is three hundred million foot-tons, enough to raise a hundred thousand tons 3,000 ft. If all its parts were moving with the speed of light, the energy would be a hundred times greater, but it is doubtful whether bodies can move at quite the speed of light. For, just as a bullet cannot move quicker than a thermally modified velocity of sound, so a body is unlikely to move through the ether quicker than the ether disturbance can get out of the way.

No doubt a large store of energy is there; the practical question is, can we get at it and utilise it? We may even ask: Is any of it being utilised already? I do not think the answer is wholly in the negative; for that the activity of radium, thorium, and other radio-active substances, is employed therapeutically is well known. That was the beginning of practical application of the energy given off.

Atomic energy may unconsciously be being utilised in other ways, too. I have lately put forward an incipient radio-active theory of vision: I surmise that in the retina there must be a substance which can be stimulated into activity by the impact of ether waves of luminous frequency, that the substance then ejects a few of its outlying electrons, and that these stimulate the nerve-endings in their immediate neighbourhood. The way in which air vibrations stimulate the auditory nerve has been fairly made out; it is a question of mechanism; but the way an etherial vibration stimulates the optic nerve has not been made out: it is not a mechanical, but an electrical question. Radiation of high frequency is known to be received and stored until it is able to eject a negative particle with whose orbital frequency it happens to agree. And certainly such a particle when ejected could be depended on to stimulate a suitable nerve ending.

It is on those lines that I would explain the extraordinary sensitiveness of the eye. For the accumulation of a few million impulses would take no appreciable time, and it is difficult to suppose that in any other way than by synchronisation with some equally rapid intrinsic motion, could matter be perturbed by the extraordinarily rapid vibrations of ether—hundreds of millions of millions per second. Nothing larger than the ultimate elements of the atom could be expected to follow such rapidity. Molecules of matter would be almost too massive and gross to be readily moved as a whole; and, besides, their movement as a whole would only result in heat.

The same sort of idea could apply to the stimulus of a sensitive photographic plate; only here the chemical atoms are attuned, as a rule, to still higher rates of vibration, and are susceptible beyond the ultra violet, into the region of X and γ rays.

The facts of colour vision suggest that the visual substance (visual purple, or whatever it is) is specially sensitive to three particular frequencies, one in the red, one in the green, and one in the violet; but there must be plentiful overlapping, so that intermediate wave lengths may produce their full effect.

The whole idea at present is in the nascent stage: only it is instructive to think that possibly atomic energy may have been utilised

in the eyes of animals all the time. It is conceivable that it may have been utilised for the light emission of glow-worms, though that is generally and perhaps rightly considered to be due to molecular or chemical energy. Atomic energy is not chemical at all, but physical—at least, when the constitutional and not the outlying electrons are in question. It is possible that the absorption of solar energy by chlorophyll in plants may also in some way utilise atomic energy, stimulated into catastrophic activity by light waves. These things are only possibilities, which observers and experimenters may do well to follow up, and, if need be, negative.

But of late an application of atomic properties in vacuo has undoubtedly been made. Ordinary electric valves depend upon the different behaviour of positive and negative particles; and an electric bulb containing a positive electrode and a hot wire cathode was employed, some years ago, as a receiver for wireless telegraphy, by Professor J. A. Fleming. When the hot wire or filament is negatively charged, a stream of electrons reach the anode. When it is positively charged, the emission is checked. So if an alternating current is received, the emission of electrons is alternatively helped and hindered, and thus the current is rectified and made capable of being received by any ordinary instrument. The cutting up into signals has to be otherwise managed, for the alternations are too quick to be acoustically perceived.

Then Lee de Forrest introduced an improvement, and made it not only a wireless receiver but a relay or amplifier. Between negative filament and positive anode, in an exceptionally high vacuum, he placed a perforated grid or coiled wire, with interstices that would let the electrons through; and instead of applying the received alternating pulses to the anode, he applied them to the grid, placed above or facing the red-hot cathode, with the anode above or behind the grid. The effect on the escaping charged particles was the same,—the stream of current-carrying particles was helped or hindered, encouraged or stopped, as before; but now a strong battery could be applied between anode and cathode, and some mechanical receiving instrument, telephone or what not, could be placed in the auxiliary or relay circuit. Weak impulses applied to the grid, according to their positive or negative sign, will now serve to control the stronger current in the auxiliary circuit; and so a received message that in itself would be hardly audible can be magnified a hundred-fold.

Electrons emitted by a hot wire are not flung off with any prodigious speed: they seem rather to evaporate off at a red or white heat, and their subsequent course is controlled by the gradient of electrical potential in which they find themselves. The force acting on them is $F = edV/dx$, and the total work done is $Fdx = edV$; that is to say, the energy generated depends simply on the total drop of voltage through which they pass. Their speed is given by

$$\tfrac{1}{2} mv^2 = e\,(V - V^1),$$

and it is usually considered sufficient to specify the voltage through which they drop, as adequately representing their externally generated speed.

They come off with *some* velocity, however; call it u; but a small opposition voltage will suffice to quench this, as gravity quenches the speed of a cricket ball thrown vertically up, and sends it down again. So it is with the electrons from a hot wire. Any potential difference greater than $mu^2/2e$ will return it whence it came. One volt rise in potential would be able to quench a speed of 450 km. per second.

That, then, is what happens between grid and hot wire. If the grid potential is negative, and greater numerically than the minimum value, the stream of electrons from the hot wire is stopped and sent back: if the grid is positive, the speed upward of the electrons is encouraged. They shoot through the pores of the grid, they reach the anode above it, they establish connection and convey the current. The auxiliary circuit, between anode and hot wire, is completed by them, and the signal is given. But this only happens when the grid allows of their passage. If the potential of the grid is adverse they never pass through it at all, but just return depressed to the hot wire. Electric evaporation is checked, just as the evaporation of water is checked in a closed space, not because no particles spring out, but because an equal number are returned. A positive grid promotes evaporation, a negative grid checks it, an alternating grid causes an alternating stream to pass through it; and the electric stream can follow every minutest fluctuation; for electron inertia is as nothing, and they respond instantly to the slightest force.

To get quickness of response the projectiles must not be allowed to bombard other molecules, so as to ionise them and render the whole atmosphere conducting. For this ionisation would not subside instantaneously, and therefore the current would not be completely under control. To avoid ionisation by impact, the

reservoir must be very highly exhausted; the current ought to depend on the projectiles themselves, not on their secondary and adventitious effects.

It is to be noticed that the kind of electric emission from a hot wire differs greatly from that stimulated by ultra-violet light or X-rays. These vibratory agents dig right down into the constitution of the atom, and eject electrons whose orbital frequency agrees with their own. The "harder" the ray, that is, the higher the frequency of the impinging radiation, the higher the velocity of the ejected electron—evidently because one of the innermost orbits is then perturbed. For in inner orbits the speed must be high, in accordance with Kepler's third law. The orbital speed varies inversely with the square root of the radius of the orbit. And the more massive the nucleus the greater the speed necessary to balance the centripetal force.

But the jostling of atoms by heat produces no such deep-seated effects. The effect of heat in a metal is as if a kind of atmosphere or crowd of stray electrons evaporated and escaped. It is unlikely that the electrons in a metal are really loose, but some of them are so slightly attached as to be practically loose—readily passed from atom to atom in the process of conduction, and readily expelled under the irregular impulses of heat.

Whether heat is the best way of promoting this electronic emission may be doubted. It seems an extravagant method, analogous to employing an electro-magnet where a permanent magnet would do, or to supporting a roof by a jet of water. But the other kind of stimuli, such as those promoted by radioactivity or ultra-violet light, do not seem to generate the right kind of docile emission. The very high-speed electrons would require too much potential to hold them down. The speed of electrons ejected by X or γ rays is definite, and depends on the frequency of the rays; but the speed of emission of electrons from a hot body is indefinite and irregular, being distributed in accordance with Maxwell's law for a monatomic gas. Moreover, the escape through the skin of a metal is equivalent to an escape against a "contact" difference of potential; and thus, in some cases, the electrons may be said to ooze rather than to fly out, and to owe their subsequent speed entirely to the external potential gradient in which they find themselves.

That state of things would be quite convenient for wireless telegraphy, since they would then be still more readily under control. The skin retardation exerted by tungsten has been measured as 4·6 volts, unless I am mistaken.

To return to practical applications of these atomic properties—for it is atomic properties rather than atomic energy that is at present being utilised. Not only is it possible to employ a relay in the way described, for the emission and receipt of wireless waves, but one relay can be used to stimulate another; and this can be done several times in succession, and immense magnification attained; for the electric stream is so rapidly responsive and docile that it can follow fluctuations that no mechanical relay could possibly follow. The rapidity of signalling thus rendered possible in the Morse Code is surprising. Of course an automatic sender, and some form of chemical or quick-responding receiver, must be used; and then the message can be as rapid as one can speak. The words are spelt out, without abbreviation, in dots and dashes; and yet the words come on to the tape at three hundred a minute, five a second or thereabouts.

It is also becoming well-known that Morse signals need not be used, but that ordinary speech itself can be thus wirelessly but electrically transmitted, with quite good clearness of articulation. Every auditory frequency is slow compared with what the atomic projectiles can follow, hence every variety of speech-sounds, vowels and consonants, can be readily picked up and transmuted into electric fluctuations. This is done at the sending end, and the aerial accordingly emits waves, which, though they have their own electric rate of vibration, succeed one another in batches corresponding to the acoustic frequencies. At the receiving end the succession of waves are picked up by the aerial there, and once more converted back into telephonic speech through the medium of one or more valve relays and appropriate devices.

There are many details, and great ingenuity has been expended in bringing this method of wireless telephony to the perfection which it has thus far attained. The whole thing is most hopeful, and splendid work is being done at wireless research stations. (I have recently seen the Government one at Woolwich, under Colonel Cusins and a devoted staff of workers, and have gone over it with great admiration.)

The interest to us, here and now, is that it is by the harnessing and practical utilisation of purely atomic properties, that all this great advance in practical electrical engineering has been accomplished. The conclusion is inevitable that much more remains to be done.

The Chairman said it gave him the greatest pleasure to propose a hearty vote of thanks to Sir Oliver Lodge for his magnificent lecture, in which he had taken them from the infinitely great—from the energy poured into limitless space from thousands of suns some ten times the size of the sun they knew—to the infinitely small, the smallest known things that they could get any inkling of, with a structure as complex as that of the solar system. It was wonderful to think that all that knowledge had been gained during the past twenty years. Engineers saw plainly that there were other sources of energy besides coal and the burning up of the oxygen in the air which must be utilised. The utmost they could do at present was to utilise water-power, and that they did in a wasteful manner. In England it was specially incumbent upon them to devote their attention to that matter. Their coal supply was only 2½ per cent. of that of the world and their water-power not much more than 1 per cent. of the world's total water-power, and engineers felt that too much attention could not be devoted to those wonderful researches of which Sir Oliver Lodge had given them so marvellous a vista. They were all indebted to Sir Oliver for giving them so clear an insight into the world of the atom, and its possibilities in the future.

Sir Henry Trueman Wood said it afforded him much gratification to second the vote of thanks to Sir Oliver Lodge for the brilliant discourse to which they had just listened. He felt assured that this series of lectures, if they were continued as they had been begun by Sir Dugald Clerk, Sir Herbert Jackson and Sir Oliver Lodge, would aid the advance and the diffusion of knowledge, and would reflect credit on the Society. It was about forty years since he had first made the acquaintance of Sir Oliver Lodge. At that time they were both secretaries of different sections of the British Association. Professor Lodge was then one of the most promising young men of science, and now he was one of the most eminent men of science in the world. It was interesting to remember that the first public announcement of his researches into electrical waves was made in the room they were now in, when Sir Oliver was lecturing on the means of protecting buildings against lightning. Those researches he had later developed into the series of investigations in aerial telegraphy for which the Society a few months ago had had the pleasure of awarding him its Albert Medal. He (Sir Henry) had heard many lectures delivered before the Society, but never had he heard one more brilliant. The subject was one of extreme difficulty, but Sir Oliver Lodge had made its general principles intelligible to his audience, and that was the test of a good lecturer. He had very great pleasure in seconding the vote of thanks.

The vote of thanks was then put and carried by acclamation.

THE PERUVIAN RAILWAYS.

Peru consists of three distinct sections, each of which extends from the extreme northern part of the country to the extreme southern. The first of these sections is the narrow, western coastal belt, arid except for its numerous river valleys. These river valleys are the avenues by means of which civilisation is slowly pushing inland; a very large percentage of the white population live in them; the country's chief ports are situated at their mouths; they produce the country's foodstuffs; in short, they are the centres of the industrial and commercial life of Peru. The second distinct section is composed of the two and, sometimes, three ranges of the Andes, which reach some of their greatest heights in Peru. In the high Andean Plateau between these mountain ranges lies hidden the mineral wealth of the country. The third section consists of the eastern slope of the Andes, or the montana, as it is called—a wild jungle still unexplored, except along the upper Amazon and its tributaries. The principal product of this montana region is rubber, which is taken down the Amazon and exported through Brazil.

The impenetrability of the Peruvian Andes is directly responsible for the fact that Peru, with an area of nearly 700,000 square miles, has only 1,700 miles of railway, or about 2·5 miles of railway per thousand square miles of area. Indirectly, railway development has been retarded by other factors. More than half the population is Indian, and a very large percentage is illiterate; political unity has been lacking, and the Government has been involved in a long series of border disputes, which has kept the treasury drained.

According to a monograph on the Peruvian Railways, prepared by the Latin American Division of the United States Bureau of Foreign and Domestic Commerce, Peru does not possess, strictly speaking, a railway system. The railways are slowly pushing their way across the coastal belt, and already two lines—the Central and the Southern—scale the coastal mountain barrier and tap the mineral region of the Andean Plateau, but no railway has yet penetrated further east than this. The montana on the east of the Andes is unconnected with the coastal region on the west, except by difficult mountain trails over which transport is impracticable. There are only three short stretches of longitudinal railway in Peru—one in the southern part of the plateau section, one in the central part of the plateau section, and one from the port of Callao north along the coast. The ocean is still the only highway available for travel from north to south.

With the exceptions of the two lines which penetrate the Andean Plateau, and the three short stretches of longitudinal line, the railways now in operation are short, isolated lines, extending from Pacific ports short distances up the river valleys and have but a single function—the connection of

(a) Included in Trujillo Railway.

interior points of a special river valley with its ocean port.

The following is a statement of the railways now in operation, together with a few details as to location, length, gauge, etc. Of the thirty-one lines mentioned, only nine are over 100 kilometres (kilometre = 0·621 mile) in length. Practically all of the railways begin at a Pacific port and follow the course of a river inland. The gauges vary from 0·61 metre to 1·44 metre. In every case the lines are dependent on the success of a few plantations or mines for the bulk of their export freight. The figures for equipment, which were purposely taken for a pre-war year, show the meagreness of the equipment of most of the lines even in normal times. (See Table, p. 75.)

In 1890 the entire foreign debt of Peru was taken over by the London Corporation of Foreign Bondholders, and in return the Peruvian Government granted that organisation certain concessions, including the control of all State railways, for a period of sixty-six years. The Peruvian Corporation was then created by the Corporation of Foreign Bondholders to administer these concessions. In 1907 a new contract was effected between the Peruvian Corporation and the Peruvian Government, by which certain disputes were adjusted and under which the railway lease was extended for an additional seventeen years.

The Peruvian Corporation controls some 1,300 miles of Peru's 1,700 miles of railways, including all the more inportant lines, with the exception of the Cerro de Pasco Railway.

The Government owns and operates on its own account three short lines, which have been built since the 1890 agreement—viz., Tumbes Railway, Ilo-Moquegua, and Lima-Lurin.

The Central Railway has well-equipped and up-to-date shops at Guadelupe, where necessary repairing is done, and also a small amount of new construction work. The Southern Railway has small but well-equipped repair shops at Arequipa. Native Indian labourers are successfully employed by both these organisations.

The Peruvian railways are not dependent on imported fuel as the Brazilian railways are, and hence have not been affected by the curtailment of the exports of coal from Europe and the United States since the beginning of the war, but the Peruvian railways had to face a fuel famine nevertheless.

The coal deposits at Jatunhussi, Oyon, Recuay, and other points are sufficient to supply Peru with all the fuel it needs, but these fields are still inaccessible and consequently undeveloped. The fuel for Peru's industrial establishments and railways is supplied by a single foreign corporation—the International Petroleum Corporation—whose holdings are near Tumbes, in the extreme northern corner of the country. As a result of a dispute between the Government and this Corporation, the tankers operating between Talara and the central and southern ports ceased running during last autumn. As the railways depend almost entirely on oil from Talara for fuel, and are equipped with oil-burning locomotives, the fuel shortage soon became acute.

In March of this year there were only three railway extensions actually under construction:—

Chimbote Railway	. Kilometre 104 to Recuay.
Central „	. South from Huancayo towards Ayacucho.
Southern „	. Cuzco towards Santa Ana.

The Recuay extension will tap an important coal deposit, which the Government is especially anxious to open up in view of the fuel shortage. The Huancayo-Ayacucho extension will make the coal deposits at Jatunhussi accessible, and will open up a country suitable for the raising of wheat and other grains. The Cuzco-Santa Ana line will be 168 kilometres in length when completed. It is a narrow-gauge line, and is estimated to cost £P500,000.

The plans of the Peruvian Government for a comprehensive railway system, which shall unite the east with the west and the north with the south, are slowly beginning to assume definite outline. These plans include two longitudinal railways, and one or more railways connecting the western coast with the navigable rivers of the eastern frontier. One of these longitudinal railways is to extend along the coastal belt, and will include the present line from Lima north to Huacho. The second will extend along the plateau section, and will include the lines from Cerro de Pasco south to Huancayo, and from Puno north to Cuzco. Three possible routes across the Andes have been discussed, but the route from Paita to the Rio Maranon and down the Maranon Valley is generally conceded to be the most practicable, and a decree authorising this railway, with extensions south to Ferrenafe and Hualgayoc, was issued towards the end of last year.

Among the extensions likely to be built in the near future may be mentioned the following: Sayan to the Oyon coal-fields, Chilete to Magdalena, Chuquicara towards Cajabamba. Government engineers have recently surveyed the last extension, which is part of the proposed longitudinal railway along the plateau, and have estimated the cost of construction.

The engineering difficulties and the almost prohibitive cost of construction have been directly responsible in the past for the slowness with which the railways have pushed up the river valleys, and preclude any chance of a rapid development in Peru such as seems likely to occur in Brazil. However, the hidden riches of the Peruvian Andes and the unknown riches of the plains beyond are bound to attract attention; while the Peruvian Government is on a sounder financial basis than formerly, and is anxious to weld the people, isolated in the various river valleys, into a united nation. Hence it seems probable that Peru will slowly push to realisation her dreams of a comprehensive railway system.

SOME CHINESE MANUFACTURED PRODUCTS OF INTEREST.

The following particulars regarding certain Chinese manufactures have been furnished to his Government by the United States Commercial Attaché at Peking :—

Dyestuffs.—Just before the outbreak of the war German synthetic indigo was imported into China to the extent of 10,000,000 taels a year, in addition to a large quantity of German aniline dyes. These had replaced in great measure the native vegetable dyes in which China was so rich ; in fact, indigo was no longer regarded as one of China's agricultural products. The native dye industry, however, by force of circumstances, has been revived, and dyes are now appearing in the list of exports.

Of first importance is indigo. It is grown quite generally throughout China for local purposes, but assumes greater importance in trade in the south. It appears that one acre of ground will produce about 6,000 lb. of indigo. According to tests made by the United States Bureau of Foreign and Domestic Commerce, the Chinese indigo contains only about 1 per cent. of pure indigo. Thus an acre will produce, with a good crop, about 60 lb. of pure indigo. The plants are cut before flowering, steeped in cold water for some days, and well stirred. After the plants are removed the water is again stirred, and slaked lime added to precipitate the dye. It 1917 China exported 78,148 piculs (picul equals 133⅓ lb.) of liquid indigo, valued at £142,000. In 1918 the figures were 83,642 piculs, valued at £183,000. Kiukiang and Swatow are the principal ports of export.

China's blacks are produced for the most part from gall-nuts, the fabrics having first to be dyed blue. The capsules of acorns are also used to produce black.

Yellow is produced from the flower buds of the locust tree (*Sophora japonica*), which are baked to a light brown colour, placed in cold water, and brought to the boil. Alum is used as a mordant. The powdered roots of *Curcuma longa*, or turmeric, are also used for a yellow dye, especially for cotton fabrics.

Red is produced from safflower, grown in Szechwan. Balsam (*Impatiens balsamina*), *Anchuse tinctoria*, and *Lawsonia alba* are also used, the latter to produce the rouge used by women. The *Rubic cordifolia*, a creeper, is used to make a deep red.

Green dyes for cotton cloth are produced from the bark of the *Rhamnus parvifolius*, found in Szechwan. Green dye is also made from the leaves of the *Rhamnus tinctorius* and other species of the buckthorn.

Brown dye is produced from the false gambier, grown extensively in south-western China. The darker browns are produced by the addition of gall-nuts and alum. A brown cloth that is very popular in the summer with the Chinese is a dyed grass cloth with a bright lustre and a waterproof appearance. Its distinctive qualities are the result of the dyes made from the false gambier.

The vegetable dyes of China are particularly well suited to Chinese rugs. These dyes will outlast the rugs. Exclusive of indigo, China exported nearly 2,000 tons of dyestuffs during 1917.

Fans.—China exports about 45,000,000 fans a year, mostly from Canton and Hangchow, the greater number being palm-leaf fans from Canton.

Fire-crackers.—China invented gunpowder and popularised fire-crackers. The cheapest kind of fire-cracker is made of gunpowder rolled up in coarse bamboo paper, with a covering of red paper, red being regarded by the Chinese as bringing good luck. Alum is used to neutralise the smoke. The Canton district is the centre of the industry. The Chinese seem to use fire-crackers upon every occasion—to speed a parting guest, in wedding celebrations, on festivals and birthdays, and to dispel evil and bring good omens. China exports about £600,000 worth a year.

Flour.—Before the war China imported large quantities of wheat flour from the United States. In fact, flour was one of the principal items in America's trade with China. High freight rates have prevented shipments of American flour to China, and now China has developed an export trade in this product. The 1917 Customs Returns show 47,500 tons (500,000 barrels) exported, more than half of which went to Russia. In 1918 the exports increased to 120,000 tons, of which more than half went to Great Britain.

There are 50 modern flour mills in China, including 15 at Shanghai, 9 at Harbin, and 7 at Hankow, the latter with an output of 1,600 barrels a day. Those at the three cities mentioned are the larger mills. The capacity of Chinese mills, exclusive of those in Manchuria, is estimated at 16,000 barrels a day. Harbin and North Manchuria produce 8,000 barrels a day. The development of the flour industry in China depends upon the development of transportation. It is safe, however, to predict that China will be able to supply its own needs in flour within the near future, if indeed it has not already done so. Manchuria and North China will offer splendid opportunities for the flour-milling industry.

Hats.—The manufacture of hats in China is certain to become an important industry. With the cutting of the queue foreign hats displaced the native styles. More than 2,000,000 rush hats are exported each year from Ningpo to the United States. A hat of good quality is being made in Szechwan of palm-leaf fibre. The extensive manufacture of straw braid in Shantung will lead to the manufacture of straw hats there.

Chinese Ink. — Chinese ink is sometimes erroneously called "India ink." It is made of the lampblack of sesame, rapeseed, or wood oil, to which is added varnish and pork fat. This paste is then mixed with glue, musk, or Baroos camphor to scent it, and some gold leaf to give it

a metallic lustre. It is pressed in carved wooden moulds, or beaten on wooden anvils with steel hammers, and then pressed into moulds. The best ink comes from wood-oil lampblack, collected on the sides of a second earthen jar placed above the one in which the oil is slowly burned. Anhui Province produces the best ink. There are many grades, the cheapest being produced from coarse soot and glue. China exported, during 1917, 116,000 lb. of Chinese ink, valued at 73,000 taels; in 1918, 127,000 lb., valued at 78,000 taels.

Lace.—Foreign missionaries in Chefoo, Shanghai, Foochow, Amoy, and Swatow have introduced lace-making among the Chinese women, and a considerable amount of lace has been exported from time to time. Silk, linen, and cotton threads are used in Chefoo, and linen and cotton in the other places. The lace is made more cheaply than is possible elsewhere because of the low wages paid in China, but a lack of enterprise in changing patterns to meet changing tastes and fashions abroad prevents the industry from assuming larger proportions. The exports, as shown by the Customs figures, amounted to 618,000 taels in 1917. In 1918 the figures reached 954,700 taels.

Mats and Matting.—At one time the making of mats and matting was an enormous industry among the peoples of the lowlands in southern Kwangtung, where the grass (*Arundo mitis*) was cultivated extensively. The seeds were planted in November and the reeds harvested in July and August. The fields are highly cultivated, and the grass grows from 5 ft. to 7 ft. high. The reed is three-cornered, and, after harvesting, is stripped and placed in the sun to dry. This work is done by women and children. When dried the strips are bundled into bales of 1 picul in weight, and disposed of in the market. For manufacture the grass is carefully sorted for quality and size. The dyeing is done before the weaving. The native loom is crude, and accounts in a measure for the lack of necessary development in the industry to keep pace with changing demands in the foreign markets. During the last ten years Japanese matting and mats have competed severely with the Canton products in the American market. The Japanese articles were better suited to the American demands, and the Canton industry was not prepared to adjust itself to the changes. Furthermore, with the war came a shortage of dyes and high freight rates, which affected the Canton industry far more seriously than they did the Japanese industry, which can depend upon Government assistance, especially in obtaining cargo space at reasonable rates. Prior to 1908 Canton exported 500,000 rolls of matting annually; in 1917 the exports were only 72,000 rolls; and in 1918, 52,000 rolls.

Medicines.—The materia medica of China is very rich. A nation with a civilisation dating back 4,000 years could hardly have done otherwise than develop a considerable number of products efficacious in combating disease. In his report, published in 1904, on the Province of Szechwan, His Majesty's then Consul-General for that province, Mr. (now Sir Alexander) Hosie, gave a list of 189 vegetable and 31 animal medicines made and used by the Chinese of Szechwan from time immemorial. He states that liquorice and rhubarb are the chief Szechwan drugs that interest foreigners. It is not to be concluded that the 220 drugs listed by Mr. Hosie (which list by no means exhausts the materia medica of Szechwan) are all, or in large part, efficacious. The great materia medica compiled in the sixteenth century is composed of fifty-two volumes, and contains 1,892 remedies. Among the drugs most used are ginseng, rhubarb, liquorice, pomegranate root, aconite, opium, arsenic, and mercury. Various superstitions exist in China, and until science comes to the aid of the people one need expect no really intelligent discrimination in the use of the many medicines in which the country abounds. Yünnan is rich in herbs and medicines. Manufacturers of drugs should find in China some valuable sources of supply of raw materials.

China exports annually more than 3,000,000 taels worth of medicines. The internal trade in medicines is enormous. Foreign exploiters of proprietary medicines have found China a rich field for their products, when extensively and attractively advertised. The Japanese nostrum "Jen Tan," translated "benevolent pill," which is being sold to the people all over China in increasingly large quantities through a most energetic and enterprising advertising campaign, uses the slogan "From death to life"—in Chinese characters, of course.

Paper.—China invented paper, but the processes of manufacture still remain crude. Rice straw is most commonly used, but only for coarse papers. Bamboo, treated with chloride of lime and soda to reduce it to a pulp, forms the material second in importance in the manufacture of paper in China. Fukien Province produces the largest quantity of paper, and Kiangsi Province ranks second, with Szechwan third.

Pottery and Porcelain.—Pottery and porcelain seem to have had their inception in China; at least, the Chinese claim the invention of the potter's wheel. China's exports of chinaware and porcelain amount to about 1,300,000 taels a year, the greater part being shipped from Kiukiang, which is the port for the Kingtehchen porcelain district. The porcelain industry at Kingtehchen, in Kiangsi, was established during the Han Dynasty as the Imperial pottery. It is now making cheap porcelains, and recently began the imitation of foreign patterns with some success. It is stated that the potters intend to imitate some of the old patterns made during the Tang Dynasty. There are more than 100 furnaces at Kingtehchen, employing about 150,000 men. The exports of pottery and earthenwares amount to about 1,000,000 taels per annum. Shanghai, Swatow, and Canton are the principal ports from which these goods are exported.

Rugs.—The war lifted the Chinese rug industry

with its centuries of indifferent activity, from a position of obscurity in relation to the West to a place of popularity and permanency in Western markets, principally because the supply of Oriental rugs from Persia and Turkey was cut off from the American market at a time when large accumulations of wealth had increased the demand. During the past few years Shanghai has been developing the rug industry, and hopes are entertained that with better organisation, and with the use of machinery, a standardised high-grade rug can be produced.

Straw Braid.—The war has played havoc with the straw braid industry of Shantung, which prior thereto had assumed a position of considerable importance in the trade of the province, although the exports varied considerably from year to year on account of changes in the style of hats for which the straw braid was used, and variations in the supplies of wheat straw, affected by crop conditions. This industry developed around the little town of Shaho, in north-western Shantung, where the large peasant population became very adept at preparing the braid for the market. Men, women and children throughout that section of the province, after the wheat harvest and while awaiting the ripening of the autumn crops, engaged, almost in a body, in the stripping, cutting, sorting, bleaching, plaiting, joining together, and bundling of the product, ready for the small buyers who go about collecting the supplies to offer to the market. It was eventually sold to foreign merchants at Tsingtau, which had succeeded Chefoo as the port of export, and then shipped to the United Kingdom, where it was re-bleached and distributed to the markets in Europe and America which used this braid for straw hat manufacture. The exports averaged about 7,000,000 taels a year from 1910 to 1914. They had fallen in 1917 to 2,400,000 taels, because of the great difficulties in getting permits and space to export the product to England, the high silver exchange, and the disturbed conditions in Shantung, which drove the trade almost entirely away from the port of Tsingtau. The American market during 1917 imported *viâ* Tientsin the bulk of the Shantung straw braid, which was bleached in the United States, some of it being shipped to South America. It is expected that the straw braid trade will revive now that the war is over.

THE RHÔNE-RHINE WATERWAY.

Some interesting particulars are given in the "*Times*" *Trade Supplement* of the plans which are now being considered by the French Government for utilising the enormous power of the Rhône. The plans may be divided under three main headings. In the first place it is intended to convert the Rhône into a waterway navigable by 1,200-ton barges. This will link up Marseilles with the Lake of Geneva and the Rhine through Lyons, and will also give Marseilles inland water communication with the northern and western coasts of France.

In the second place it is estimated that the Rhône is capable of producing annually electricity equivalent in power to that furnished by 5,000,000 tons of coal. This energy is to be furnished by nineteen generating stations along the river between Marseilles and the Swiss frontier, with a total horse-power of nearly three-quarters of a million. A large amount of this power will be absorbed by Lyons and Marseilles, the two principal manufacturing towns of France. The Paris-Lyons-Mediterranean Railway will probably electrify a part at least of its system, and the proposals contained in the scheme also safeguard the claims of Paris and the Departments of the Seine and Seine-et-Oise upon the new source of national energy to be opened up.

The third heading is irrigation. The Rhône valley is exceedingly fertile, but in its lower regions irrigation is necessary for all crops except the vine.

It will, no doubt, be many years before the full programme can be carried out. All that the Bill, which is now before the French Parliament, attempts to do is to sanction the general ideas, without going into details. It fixes the general limit of expense and the proportion of the State's contribution. It determines the special rights of riverain regions over the power produced, and approves of an agreement being come to between the Swiss and French Governments, both for the exploitation and the construction of the new water-link between the two countries.

The total cost of the scheme is estimated at 2,500,000,000 francs. In the event of the State not being able to find within three years one contracting group able to carry out the whole work, it will be permitted to grant smaller concessions, each of which will carry control, under State guidance, of one of the six sections into which the Rhône system has been divided. These sections terminate at the following points: the sea, the junctions of the Gardon and the Isère, of the Saone and the Saviere Canal, and the Swiss border, the region of Lyons forming a section by itself. Two great barrages will have to be built; large sections of the river will have be "turned," by the construction of canals, and seventeen locks, each capable of accommodating 1,200-ton barges, must be made. In addition to this, nineteen power-stations will have to be provided, and irrigation arranged for 642,000 acres.

OBITUARY.

SIR JOHN JACKSON, C.V.O.—Sir John Jackson died suddenly on the 14th inst., whilst on a visit to Godalming.

He was born at York in 1851. At an early age he entered workshops at Newcastle, and subsequently studied engineering at the University of

Edinburgh. He secured his first contract at the age of twenty-five, and in the following year he carried through the difficult task of building in quicksands the Stobcross Docks at Glasgow. His next works were docks at Middlesbrough, Hartlepool, and North Sunderland, and then came his first contract with the War Office—the extension of the Admiralty Pier at Dover. He also constructed the commercial harbour there.

The last eight miles of the Manchester Ship Canal he carried out in two-thirds of the contract time, and on the completion of this he received his knighthood. Other important works of his were the laying of the foundations of the Tower Bridge, the docks at Swansea, Burntisland and Methil in Fifeshire, the deep lock at Barry, and the extension of the Admiralty works at Keyham. The last-named work took ten years to complete, and cost nearly £4,000,000.

In addition to his numerous works in this country, Sir John carried out many contracts in the overseas dominions and abroad. The chief of these were the new naval harbour and graving dock at Simon's Town, Cape Colony, the improvement of Singapore Harbour, the new breakwater at Victoria, British Columbia, and the arsenal at Ferrol. He built for the Chilian Government the line from Arica to La Paz in Bolivia, which crosses the Andes at a height of 14,500 feet, and he carried out the great irrigation works designed by Sir William Willcocks for Mesopotamia.

Sir John Jackson was elected Unionist M.P. for Devonport in 1910, and continued to act as one of the representatives of the borough till 1918, when he retired. He had been a member of the Royal Society of Arts since 1889.

GENERAL NOTES.

THE WORLD'S SUPPLIES OF WHEAT.—The important question of the future of wheat production, with special reference to the Empire, is dealt with at length in the current number of the *Bulletin* of the Imperial Institute. The annual production of wheat in the world prior to the war amounted to about 110,000,000 tons, the largest producers being the Russian Empire, with an output of 22,000,000 tons, and the United States, which provided nearly 19,000,000 tons. During the war the production in Europe as a whole, and in Russia in particular, decreased considerably, but outside Europe there was a great expansion. The acreage under wheat in Canada, the United States, Argentina, India, and Australia in 1918 was over 25 per cent. larger than the average acreage for the five years before the war, and it is considered that, at the present time, there is a sufficiency of wheat, even without the help of Russia, to meet the requirements of the world. As regards the future also there is reason for optimism. There are vast areas of land suitable for wheat-growing yet to be opened up in Canada, Australia, South America, Siberia, and other countries, whilst the present low average yield of 13 bushels per acre is susceptible of great improvement. In recent years the increase in the world's production has been due, to a great extent, to an increased yield per acre, and there is every reason to believe that with the introduction of improved drought- and rust-resistant varieties, the rise will be even more rapid in the future.

UTILISATION OF SLATE WASTE.—A new use for the vast quantities of waste material produced in quarrying slate has, according to the *Chemical Trade Journal*, been developed in Carnarvonshire, where a company is powdering the waste and selling it as a filling material. It is said to be useful in the manufacture of asphalt, bricks, cement, abrasive soaps, cleansers, glass, linoleum, moulded and mechanical rubber goods, pottery, slabs and tiles, distempers, paints, insulators, etc. It produces bricks which are at the same time dense, strong, and hard, and which show a considerable saving in manufacturing costs. The silica content ensures that they are capable of withstanding a very high temperature.

COLONIAL AGRICULTURAL DEPARTMENTS. — A committee has been appointed by the Secretary of State for the Colonies to consider whether the staffs of the above departments are adequate and sufficiently remunerated, and to make recommendations for improving the arrangements for recruiting those staffs. The chairman is Sir Herbert Read, and the other members of the committee are Sir David Prain, Sir Henry Birchenough (Empire Cotton-Growing Committee), Professor J. B. Farmer, Sir Francis Watts, and Major R. D. Furse.

GERMANY AND OVERSEAS MARKETS.—In spite of the difficulties confronting Germany in the resumption of world trade, German traders, says the *Board of Trade Journal*, are showing great activity in their efforts to resume pre-war connections in all parts of the world. Certain Germans in Brazil have recently forwarded samples of certain local products to Rotterdam for Germany. The samples comprised 43 packages of a net weight of 3,269 kilos. The above is interesting as it shows that by forwarding samples the Germans, with their usual thoroughness, have again begun at the beginning. Consignments of German goods have also arrived at Bahia. One in particular, which was sent out through an intermediary, consisted of small ware of all descriptions. Again, a well-known German house at Solingen has placed its catalogues in circulation at Bahia, offering scissors at 8 to 51·60 marks per dozen plus 30 per cent. over 1914 prices. This quotation brings the price of the most expensive scissors manufactured by this firm to between 5 to 6 marks per pair. The largest and best quality of scissors would cost 1·4 milreis or five to six times less than the same size or quality coming from the United Kingdom or the United States of America.

Journal of the Royal Society of Arts.

No. 3,501. VOL. LXVIII.

FRIDAY, DECEMBER 26, 1919.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

FRIDAY, JANUARY 2nd, at 4.30 p.m. (Indian Section.) A. P. MORRIS, B.Sc., A.M.Inst.C.E., Provincial Art Officer, Burma, "Burmese Village Industries: their Present State and Possible Development." SIR HARVEY ADAMSON, K.C.S.I., M.A., LL.D., Lieutenant-Governor of Burma, 1910-15, will preside.

JUVENILE LECTURES.

The usual short course of lectures adapted to a juvenile audience will be delivered on Wednesday afternoons, January 7th and 14th, 1920, at 3 p.m., by MR. LOUGHNAN PENDRED, M.I.Mech.E., Editor of *The Engineer*, on "Railways and Engines." The lectures will be fully illustrated with working models and lantern-slides.

Special tickets are required for these lectures, and no person can be admitted without one. A few tickets are still left, and these will be issued to Fellows who apply for them at once.

REPRINT OF CANTOR LECTURES.

The Cantor Lectures on "Coal and its Conservation," by WILLIAM ARTHUR BONE, D.Sc., Ph.D., F.R.S., Professor of Chemical Technology at the Imperial College of Science and Technology, have been reprinted from the *Journal*, and the pamphlet (price 1*s.* 6*d.*) can be obtained on application to the Secretary, Royal Society of Arts, John Street, Adelphi, W.C. (2)

A full list of the lectures which have been published separately, and are still on sale, can also be obtained on application.

BOOKS OF TICKETS.

Every Fellow is entitled to admit two friends to the Meetings of the Society (with the exception of the Juvenile Lectures, for which special tickets are necessary). Books of tickets for this purpose can be obtained on application to the Secretary.

LIST OF FELLOWS.

The new edition of the List of Fellows of the Society is now ready, and copies can be obtained on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

COLONIAL SECTION.

A meeting of the Colonial Section was held on Tuesday, December 9th, 1919; Lieut.-Colonel L. S. Amery, M.P., Under-Secretary of State for the Colonies, in the chair.

The paper read was—

PROBLEMS OF THE WEST INDIES.

By SIR EDWARD DAVSON.

The world convulsion, of which the aftermath is now being reaped, has left the nations face to face with new problems of every kind—social, political, financial, and commercial. To this country one of the most important is the problem of the Empire, what its future is to be, how far the political ambitions of our Dominions and Colonies can be satisfied, to what extent Imperial unity and solidarity can be hastened and achieved, and how we can best develop those resources which have in the past been partly neglected, but which it is now both a duty and a necessity to develop to the utmost of our power.

This problem is occupying men's thoughts, not only at home but throughout our Overseas possessions, and our West Indian Colonies are no exception. In accordance with the title of this paper I shall this afternoon confine myself to them, and venture to set before you their aims and aspirations, and also the steps that, as I think, should be taken to realise them.

Let me in the first place remind you of the geography of the West Indies; how, starting from British Honduras in Central America, we pass east to Jamaica, and thence farther east to the Virgin Islands; how, like the arc of a bow, the islands then run south to British Guiana in South America, thus almost encircling the Caribbean Sea. They have an area of 111,000 square miles, a population of 2,100,000, and a trade of £30,000,000.

Let me also remind you that they are our oldest group of Colonies, and in the early days were a source of wealth to Great Britain. Then came the lean years when they suffered greatly, and when they felt that they were neglected and almost forgotten; and then the war, when, realising how much was at stake, they, like other parts of the Empire, gave all they could of men and money for the cause. As elsewhere, the war brought its sorrows and the end its burdens; but, nevertheless, in one sense it has brought advantage, for as the world-wide need of foodstuffs has arisen, so have the products of the West Indies been in demand, and these Colonies have consequently reached a state of prosperity which they have not enjoyed for more than a hundred years.

I do not know if it is this prosperity which has drawn the attention of the United States, or if it is rather a development of what may seem to them a natural and laudable desire to make their sphere of influence in Caribbean waters single and complete; but the fact remains that the acquisition of the British, and also French, West Indies, as a development of the Monroe doctrine, has recently received much attention in America.

The argument in favour of this has been somewhat ingeniously put by Professor Shepherd, of Columbia University, in an address delivered to the Academy of Political Science at Long Beach, where he gives three reasons why, as he puts it, the Caribbean Sea should be made into an American lake—the first being that they, the States, need these areas themselves; the second, that the European owners do not; and the third, a natural consequence of the two preceding, namely, that the owners ought to turn them over to the States for the good of all concerned. The argument for our handing them over is also stated as follows:—

"If Great Britain and France are to derive material compensation from a victory rendered certain by the opportune aid of the United States, it is only fair and just that they should turn over their Caribbean possessions to this country as a fitting token of gratitude for our support."

I do not think that there is any need to take up your time in discussing this proposal, nor need I do more than refer to the singular suggestion recently propounded by Lord Rothermere and others, that we should sell the West Indies to the United States, in order to obtain money to improve our financial position. The suggestion has raised a storm of indignation in the West Indies, which has only been appeased by Lord Milner's recent emphatic declaration that we had no intention of parting with the West Indies. I can only add that the suggestion shows a strange ignorance of the theory and spirit of Empire, which is based on something deeper than Treasury balances and rates of exchange. We shall restore our financial position by increasing our production, and the West Indies mean in the future to play a not unimportant part in bringing this about. Self-determination is a phrase of the moment, and people on both sides of the Atlantic can rest assured that the West Indian Colonies have every determination to remain under the British flag.

These matters, on which I have perhaps dwelt unduly, lead me to the consideration of a further suggestion that has been made as to the future of the West Indies. The Dominion of Canada claims that if the West Indies are to be taken care of by any Western Power, they should more fitly be absorbed into the Dominion. Canada, so it is argued, needs tropical territories and outlets for her exports to such lands even more than the United States, which already has certain possessions and spheres of influence in those parts, while she could hasten their development to a greater extent than can England, with its many obligations in other directions. This is a proposition that obviously calls for greater consideration than the other, although the West Indies have never lost their belief that England itself would one day—and we hope that the time has now arrived—realise their potentialities, and do its best to develop their resources.

Let me say at once that there is no existing desire in the West Indies to have political federation with Canada; but even if there were there is one, to my mind, insuperable difficulty in the fact that Canada, in absorbing two millions mostly of coloured people in their own population of eight millions, would be giving West Indians a great share of political power in Canadian affairs. The only alternative

would be to treat the West Indies as dependencies under some form of Canadian Colonial Office Government; but this does not appeal to West Indians, who feel that it is better to bear the rulers they have than fly to others that they know not of.

Do not think that this means any lack of good feeling towards the Dominion; on the contrary, the West Indies fully appreciate all that she has done for them in the past, and look forward to a constant increase in the future in the trading relations which have been happily established by the Canadian West Indian Reciprocity Agreement in 1913. My own feeling is that it is better to let these relations grow and ripen, rather than try to force any development such as that which I have indicated.

But it is said—and I think that this is the root cause of both these proposals—that in these days of combination and concentration, it is economically impossible to regard as a permanence a scattered group of colonies lacking in political cohesion and commercial unity, each pursuing its own little path, and being overlooked and over-ruled when it comes in contact with the outside world, and in this I am inclined to agree. The history of Imperial development emphasises this view, for we see how different groups of colonies—in Canada, in Australia, and South Africa—some of them starting as Crown Colonies, have gradually drawn closer together until they have become federated into a Dominion, a Commonwealth, or a Union. Both then for their own advancement and protection, I think that the West Indies must aim at becoming in some form federated, and when that is accomplished, then will be the time to consider whether they would derive advantage by a further federation with another part of the Empire.

The problem of West Indian federation is, however, a difficult one, for their geographical position in relation to each other as islands creates obstacles which do not exist in considering the federation of contiguous colonies on the mainland; while the different forms of Government in the West Indies, ranging from the full representative Government of Barbados to the purely Crown Colony Government of the lesser islands, do not facilitate a solution of the problem. In the history of the West Indies, attempts have been made to combine or federate various parts, but these have always proved unsuccessful, except in the case of the Leeward Islands Federacy, which still exists, and which is the only Crown Colony federation in the Empire.

It does not follow, however, that because attempts have failed in the past they should necessarily fail in these days of more enlightened views and broader vision. Various schemes have been put forward, notably one by Mr. Gideon Murray, late Administrator of St. Lucia. which aims at creating a central Federal Council out of the various forms of local government, and which has aroused much interest in West Indian circles. Another proposal has been to extend the Leeward Island Federacy to Trinidad and the Windward Islands, thus creating in the first place a federation of the West Indian Crown Colonies, and leaving Barbados and British Guiana with their more representative Government, and Jamaica, the Bahamas and British Honduras for further and later consideration in this respect.

There are, however, two essential points to be borne in mind. The first is that there must be what I may call the "will to federate," and while it is undoubted that this is already beginning to grow, one finds at the same time the opinion largely held that federation, like the Canadian question, should not be forced, but should be allowed to grow and ripen as people increasingly appreciate the advantages of a constantly developing community of thought and action.

And the second point is, that if a people aspires to become a federation or commonwealth, if it aims at taking its place with other colonies in the councils of the Empire, it must not only develop its material life to the utmost of its capacity, but it must also educate itself, it must so raise its standard of thought and extend its vision that it can rightfully claim that its opinion may be treated with respect in considering the greater problems with which it would then be faced.

As regards the first point, the "will to federate," which in its elementary form simply means a growing appreciation of the benefits to be derived from a unity of thought and action—this, as I have said, is already in process of evolution. For some years past, conferences which representatives of most of the West Indian Colonies have attended, have from time to time been held to consider such matters of common interest as mail contracts, quarantine regulations, and the establishment of a West Indian Court of Appeal. The most recent conference was held this year to consider customs matters, and its very important findings are now being considered by the various Governments. Amongst other recommendations it has proposed the introduction of a

Model Customs Ordinance and a Customs Duties Ordinance, by which the laws and regulations, and also the classification of articles, should be identical in all the Colonies, instead of being, as now, so hopelessly diverse as to prevent any comparison between Colonies or any compilation of combined figures for the benefit of those who wish to study West Indian trade statistics.

Two very important resolutions were also passed, one being that a system of free tariffs in colonial products (other than rice and oil) should be established between British West Indian Colonies and British Guiana, which means that in future the products of any one Colony could be imported into any other Colony without payment of duty. The other was that the Colonies concerned should enter into a Customs Union, and adopt a uniform tariff under which the receipts should be pooled and allocated to each Colony in proportion to its dutiable imports. This establishment of free trade between the Colonies, and this right to move duty-paid imports from one Colony to another without payment of further duty, would be a great step forward. The Collector of Customs in Trinidad, in his report to the Government, says of this: "Its adoption would draw the Colonies closer together in trade and other questions, largely increase trade and communication, and secure for some of the smaller Colonies a reasonable tariff instead of the unsound and indefensible tariffs with which they are now burdened. It would also place the Colonies forming the Union, whose total trade is some £30,000,000 per annum, in a much stronger position to negotiate trade agreements, etc., than they are now."

Yet another resolution recommends the establishment of a Central West Indian Customs authority; and it will be obvious how much the resolutions, if carried out, would tend to bring these Colonies together in a bond of common material interest.

I have already mentioned the formation of a Judicial Court of Appeal, the enabling Act for which comes into force next July. This will be composed of the Chief Justices of the various Colonies, and will travel round the West Indies to hear appeal cases. It may tend to a reduction in the number of local judges, and it will ensure that the judge who tries a case does not also sit on the same case in appeal as frequently now happens. The formation of this Court has been facilitated by the abandonment of Roman-Dutch Law in favour of English Common Law in British Guiana, a step largely due to the initiative of Dr. Nunan, the Attorney-General of that Colony.

I would also like to mention the work of the Associated Chamber of Commerce, which held its first meeting in 1917, and of which the second meeting is to be held next February, when it is hoped that delegates from all the West Indian Colonies, and also representatives of affiliated associations in England and Canada, will be present. It is intended that all matters bearing on trade and commerce and cognate subjects will be fully discussed, and I need hardly point out the benefit which must be derived from men from the different Islands meeting together, learning each other's point of view, finding out where their various interests clash or agree, and then coming to decisions which are for the benefit of the whole rather than a part.

The Association is but in its infancy, and I look to see it, as it matures, greatly extend its work and influence I look to it, as it becomes financially stronger, to keep in close touch with all the Chambers, to be a kind of clearing-house for them all, collecting and disseminating trade news and statistics by its publications, and, in fact, to become what I may call the Central Council of a Commercial Federation.

I have mentioned the foregoing as illustrations of the growth of the will to federate, of the increasing tendency for each colony to work in harmony and union with the others. I have also spoken of the need of the West Indies to use—or perhaps I should say to continue—their efforts to raise their people, both physically and mentally, to as high a status as possible. As a means to this, I should place education first, for it is a truism, although perhaps not fully recognised in former days, that the better and more fittingly you educate people, the better citizens they become. I have used the words "more fittingly" because misdirected education may sometimes tempt people out of their environment, and may only cause the young generation to seek such walks in life as there is, except for the few, little opportunity to pursue. Compulsory education, greater opportunities for secondary education, an increase of technical schools and agricultural training, are all things to be aimed at, but before this there is the need of finding and adequately paying as teachers those who have the gift of teaching, and seeing to it that they themselves are taught what to teach and how to teach it.

In this connection an interesting memorandum has been put forward by Mr. Popham Lobb,

Administrator of St. Vincent, in which he refers to the underpayment and want of vocational training of teachers in the primary schools in the West Indies, although in some of the larger Colonies there may be less to complain of, and in Jamaica an Educational Conference has just made important recommendations on this subject.

Mr. Lobb remarks as follows :—

"Speaking subject to correction, I believe it is a fact that with few exceptions the teaching staff in the primary schools in the West Indies have themselves received no education either in subjects or methods other than that derived from the study of text-books in their spare time. Conditions are worse in this respect in the smaller Colonies; but it will hardly be contested that there is room for improvement in the vocational training of teachers, or that it would be followed by a marked improvement in the pupils' standard of knowledge. Such training cannot be satisfactorily provided except by a central institution, which would be well worth the cost for that purpose alone.

"Under present conditions, the teachers, so far as my experience goes, work as isolated units lacking the consciousness of belonging to one of the highest of all professions, and the stimulus that comes from a sense of common effort in a great cause. A sound training, received in common with teachers from other Colonies, would not only increase the value of their work, but do much to broaden their outlook and interests."

Mr. Lobb therefore suggests the institution of a Central College, which would provide a course of training for primary school teachers, to include thorough instruction in hygiene and sanitation.

The two last subjects are rightly included, because there is no doubt that the question of health conditions is one of the most important of those with which the West Indies has to grapple. I shall not burden you with statistics, but it may be accepted that while conditions and specific diseases vary in different colonies, yet the amount of disease and consequent reduction in human efficiency is very great. In the past such diseases have been considered as unavoidable concomitants of life in the Tropics, but medical research in recent years has shown that tropical diseases can be greatly reduced if not entirely eradicated by the adoption of hygienic and sanitary principles. We have already removed yellow fever, which was once the curse of the West Indies, and the Americans have shown us how malaria can be got rid of by their work in the Panama Canal zone. It may be hoped, therefore, that British Guiana, for instance, will be able, as funds permit, gradually to reduce malaria, which has so injuriously affected its population in the past; but as to the eradication of which, I am glad to say, the local Government is now quite alive. In addition, there are in the West Indies such diseases as filariasis, ankylostomiasis, leprosy, pellagra, tuberculosis and venereal diseases, which all take their toll, while infantile mortality stands at a much higher percentage figure than should be the case.

These points, I know, are being more and more realised; but lack of funds and the absence of specialised knowledge and central control are obvious hindrances to any appreciable amelioration. In this respect three things are required: First, that instruction in the principles of hygiene and sanitation should be given to children in schools, as it is obvious that it is easier to train children under supervision than adults who are not; while it is also borne in mind that such instruction cannot be given unless the teachers themselves have already been instructed. Secondly, the medical services of the West Indies should be put on a better footing, and salaries and possibly pensions should be sufficiently large to attract the best type of medical officer. I am glad to say that this matter is receiving the attention of the Colonial Office, and that Lord Milner has appointed a committee of inquiry to investigate the subject, and one may hope that this may even lead to the possibility of assimilating the medical services of neighbouring Colonies. The third point is that individual diseases should be attacked in turn by an organised scientific body, well equipped both financially and scientifically. The Rockefeller Institute furnishes an example of what I mean, for its services to the West Indies in fighting parasitic diseases have been of the utmost value. I feel, however, that the health improvement of our Colonies should not be dependent upon the generosity of an American institution, and I hope that the London School of Tropical Medicine, which I understand is about to enlarge its sphere of usefulness, may be able to undertake some of this important work. In this connection Dr. Louis Sambon, the eminent specialist in tropical diseases, has put forward an interesting proposal to transfer part of the tuition in tropical medicine to these Colonies, where not only the necessary material can be found, but the

surroundings and the sanitary measures at present existing can be studied. At the same time a complete medical survey of the whole group is suggested, with a view to establishing the distribution of the various diseases, their œcological factors, and the best methods of prevention.

Time prevents my dealing further with this mportant subject, but the idea of organising a specialised campaign against these diseases is one that must appeal to any one who realises how seriously they may retard the development of our Colonies.

I have referred to their serious effect upon the supply of efficient labour, and I would like to touch on another point in the labour problem, which is that one frequently hears the cry of a shortage of labour, and at the same time finds large numbers of labourers emigrating to foreign lands. It is well known that in past years the West Indies have been looked upon as a source of labour supply for developing neighbouring foreign countries, as witness the construction of the Panama Canal, the Madeira-Marmore Railway in Brazil, the development of bananas in Costa Rica, and of sugar in St. Domingo and Cuba; and even now recruiting is being carried on in Barbados and Jamaica for the last-named place. It has sometimes been said that the West Indian labourer is indolent; but, apart from the effect of diseases, this statement cannot be maintained, as his services are so much in demand in those countries to which I have referred, where he has the reputation of being a hard and conscientious worker. It may be that he works best when away from his home environment; but if so, surely the right course is to encourage him, should he show himself dissatisfied with the conditions of his own island, to migrate, not—as now—to a foreign country, where he is removed to a large extent from the protection of the flag, but to one of the other Colonies where his services are in greater demand. One would instance in this connection the Colony of British Guiana, whose resources are at present scarcely touched owing to the absence of a labour supply, and where—all things considered—wages as good as elsewhere can be earned. Wherever employers can offer satisfactory conditions of life, suitable dwellings, comfortable transport and an adequate wage—which they have not always been able to do in the past—I am sure that they can compete with foreign recruiters. I look forward then to seeing Labour Exchanges established among the different Colonies where the attractions of such employment, the terms of contracts, and the conditions of life can be put before intending emigrants.

In dealing with prospective developments, I must not omit to mention the proposal, advocated by Sir Francis Watts, Imperial Commissioner of Agriculture, for the formation of a College of Tropical Agriculture. This matter has recently been considered by a Committee appointed by the Secretary of State for the Colonies. The report is not yet published, but it is to be hoped that it will favour the establishment of such a college in one of the islands, where not only may West Indians, who are anxious for education in agricultural science, receive training, but where more advanced pupils, such as post-graduates from universities, may be able to study the higher branches of agricultural science. Such a college would be of more than local benefit, as it would give an opportunity for study which is so far unobtainable for those who desire to receive such training throughout the Empire.

Nor must I omit to refer to the excellent work of the Department of Agriculture itself, and to express the hope that this work may not only be continued, but may be put on such a financial footing as to enable it to increase its activities and usefulness. Nor yet again must I omit to mention the really useful work which is being done by the West India Committee in ventilating West Indian affairs in this country, and in generally helping to enhance the welfare of these Colonies.

Finally, I should like to say a few words about trade and commerce, for even as these higher aims which I have endeavoured to indicate depend upon the means to carry them out, so do the means depend—so far as the West Indies are concerned—not only upon the production of wealth, but also upon the securing of profitable markets for their products, and of efficient means of transport to and communication with those markets.

As regards trade, the West Indies have for many years claimed that their future development and prosperity depended largely on their preferential treatment in the home markets, and that they, as loyal Colonies, had the right to look for more favourable treatment from the Motherland than the stranger whose interests could never be identical. Their hope has now been realised by the preference granted this year, which is therefore not only of material benefit, but which—and this is equally important—has shown that the home country accepts their view, whereby they are correspondingly heartened and encouraged. It is probable that

the West Indies may reciprocate by increasing their preference to 50 per cent., and it is to be hoped that this increase will also be extended to Canada, and that Canada will reciprocate to a like extent. Thus, as I hope, we may see the initiation of an Imperial Preference of 50 per cent. which may gradually extend throughout the Empire. A further suggestion has been made that British Guiana should form a Customs Union with Canada, but I confess that I should like to see a West Indian Customs Union first, and that, to me at least, the difficulties seem to outweigh the advantages. Nevertheless, one must not dogmatise too early, and the question may be worth close and scientific investigation. But, apart from this, these preferential arrangements, both with Great Britain and Canada, if they can be made enduring, should solve the problem of finding markets for West Indian products.

As regards transport, *i.e.* steamship services, the West Indies have little reason either now or during the war to complain of cargo tonnage, as they are well provided for in this respect, not only for their trade with England, but also with Canada and the United States. The question of a passenger and mail service to this country is, however, a more difficult one, and concerning this a committee appointed by the Colonial Office has just presented a report. Figures show that a high-class service of this kind, such as is desired, cannot be self-supporting, and it is clear that at the present time the cost of building would make the amount of subsidies required too heavy a burden. The cost will presumably decrease in time, but the solution may possibly be found in the provision of more modest passenger and cargo vessels, which may provide at least adequate passenger accommodation while enabling the ships partly to pay their way through their freight-earning capacity. Should it prove feasible to combine the present Canadian-West Indian subsidised line with an English-West Indian line, by running through steamers to Canada from England *viâ* the West Indies and *vice versâ*, it is probable that certain economies might be effected.

The other point is that of cable communication. In days of modern commerce, the cable is to the business firm what the voice is to the individual, and, if this be accepted, then one must confess that recently West Indian firms have been almost inarticulate. Frequently broken cables, alleviated sometimes by spasmodic efforts at wireless, but more frequently only by sending messages by ships, have resulted in incredible delays, and sometimes in the total disappearance of messages *en route*. Except in the case of Jamaica, the only existing cable runs through divers foreign lands, and the request of the West Indies that they might have a new all-red cable service has so far fallen on unheeding ears. This is the more strange, as the subsidies at present being paid by England, Canada, and the West Indies are more than sufficient to provide both interest and sinking fund on the required outlay. One may hope, therefore, that the Government, who to my mind should be the actual owners of all such strategic cables, may have such a scheme carried out by the time that the existing contract expires. In this connection I should also like to refer to the press of the West Indies. This is a valuable asset to them, and some of their papers can compare favourably with those of the Dominions and other Colonies. But the potency for good of the press must largely depend on its supply of news, and this alone would justify the call for a better cable service; nor can one hope to break down insular prejudice and mutual lack of knowledge, unless one has the lowest possible press rates between the different islands.

And now I have finished. I have not given you any description of the West Indies or their industries, and I have touched only lightly on their existing conditions of life. I have endeavoured rather to deal with those problems which lie before them, in the satisfactory solution of which, rather than in the attempted fomenting of sectional or racial prejudice—which one sometimes notices with regret—lies the best prospect for the abiding welfare and happiness of all concerned. And further, out of that growth of common interest, and of the increasing realisation of the benefit of co-operative progress which I have ventured to indicate, out of that, as I believe, will arise a new West Indies, strengthened, united, and more powerful, which will in due time be able to take a place in the Imperial scheme worthy of the Colonies which a hundred years ago were called the brightest Jewels of the Crown.

DISCUSSION.

The Chairman (Lieut.-Colonel L. S. Amery, M.P., Under-Secretary of State for the Colonies), in opening the discussion, said he thought they could all congratulate themselves on having come to hear Sir Edward Davson's paper. At the very outset Sir Edward had given the discussion of West Indian problems its proper framework and background by treating them as part of the whole great problem of Empire, of Imperial unity and

development, by the solving of which they would be able to solve the problems which affected them locally. He was convinced that the problems which faced England and each separate portion of the Empire in the years to come could never be successfully dealt with if they were tackled in a purely local spirit; they could only be solved as part of the whole problem of Imperial development. To obtain the fullest economic development and national life of each part of the Empire required the co-operation of, and the maintenance of effective unity with, the rest of the Empire. From the economic point of view above all, the hope of bringing back prosperity to this country, and of achieving a higher level of prosperity than had ever been enjoyed in the past, in spite of the immense burden of debt which lay upon us, could only lie in the development of the Empire. He agreed most whole-heartedly with Sir Edward Davson's view that to restore our financial position we must look to the keeping and developing of the Empire, and not to getting rid of it. For his part, he attached no importance whatever to the ill-informed suggestions which had been put forward, or which might be put forward in the future, to the effect that the British Empire should thrust out, as part of a cash transaction, any essential part of that Empire, and above all those Colonies which had played so great a part in British history in the past, and which he believed would play as great a part in the future. Sir Edward had also touched upon the possibility of political union of the West Indies with Canada. That, of course, was on an entirely different plane from the other suggestion; there was no question of the Flag involved. It was merely a question of practical administrative considerations, some of which Sir Edward had drawn attention to. Whatever the difficulties in the way of such a union might be, he believed that closer relations, both of trade and personal intercourse, between the West Indies and Canada, as well as between the West Indies and the United Kingdom, would be of advantage to all three countries. He did not think that all the development in the Empire should be done by the United Kingdom as the centre, regarding the other parts as mere dependencies and satellites. He regarded Imperial preference as a means by which each part of the Empire should take the closest interest in the development of every other part, and by its trade mutually help the development of every other part. England had established, and he believed for good and all, the principle of Imperial preference. That principle was of value, not only in the material assistance which it gave to some parts of the Empire, and more particularly to the West Indies, but also as the assertion of a very definite new conception of Imperial development. That conception was not one of exclusion or monopoly. By Imperial preference they did not mean that they should stop trading with the outside world. But they did feel that the advantages secured by each part of the Empire helping every other part were so great that wherever possible they should try to put inter-Imperial trade first, and he had not the slightest doubt that the development of that principle, not only in the matter of customs duties, but in every other sphere, would mean an immense development within the Empire. It only meant the conservation of economic energy within their frontiers. He had been very pleased to note the emphasis Sir Edward Davson laid on the problem of education. If economic development was required, a beginning must be made by developing the individuals who were going to do the work. He was also glad to see the way in which Sir Edward linked up health with education. In the West Indies, and many other tropical regions, the alphabet of education ought to be education in hygiene. Children should be taught the elementary principles of sanitation and hygiene before they were taught their letters. Equally essential, at the other end of the scale, was higher education, the higher work of research, and the training of the few teachers and experts whose work could be of such enormous value to the people for whom they laboured. He was glad Sir Edward had paid a tribute to the remarkable work achieved by the Imperial Department of Agriculture, which owed its initiation and encouragement to the late Mr. Joseph Chamberlain. He thought that that work, which had already been of great value to the Empire, would receive a further impetus by the creation of a College of Tropical Agriculture in the West Indies, which would be the centre for study and research for the whole tropical world.

Sir Sydney Olivier, K.C.M.G., C.B., said he would first like to congratulate the Chairman on the announcement which had appeared in the papers that morning, that he would assume the full duties of the Secretary of State for the Colonies during Lord Milner's absence. Next, as a man who had all his life been interested in the West Indies, and who had studied their problems both in the Colonial Office and on the spot, he would like to join the Chairman in his congratulations to Sir Edward Davson on his exceedingly able paper. Dealing with Imperial preference, he thought that the preference accorded to the West Indies was only the discharge of an obligation which had been long overdue, but at the same time he thought it would be a mistake to encourage the West Indian Colonies to rely upon, or to think that they could not succeed without, the help of a 50 per cent. Imperial preference. It seemed a little injudicious to hold out that hope. Even the present preference, although of great benefit, was not sufficient to ensure the stability of, say, the West Indian sugar industry, unless the methods of production were considerably improved, because the competition of such a country as Cuba was so great—there were factories in Cuba turning out from 50,000 tons to 100,000

tons a year with very cheap cultivation on virgin soils—that she had an advantage over the West Indies which was very much more than the preference which had been given to the latter. With reference to the question of labour, Sir Edward Davson said he thought that the British West Indies might be able to offer conditions of employment as good as those given by Cuba and other countries. That was a rather sanguine view. Cuban factories were offering 3½ dollars a day to the men who cut their cane harvest. That caused a severe draft on West Indian labour supply; no one in British Guiana could offer as much. But, as Sir Edward had said, if West Indian planters would take advantage of the high prices now obtaining for their products—especially sugar —and lay down improved factories and offer their workmen a larger share in the prosperity of their undertakings, he thought they would be able, if not to attract immigrants, at any rate to retain their own labourers. With regard to the political future of the West Indies, he wished to make a complaint which all who were interested in them would endorse. Whenever people in Great Britain, though with the best possible intentions, turned their attention to the West Indies, they began by offering them large schemes of political reorganisation, such as annexation to the United States or federation amongst themselves. They always offered wide generalities of that sort, which made no appeal to any West Indian. People in Great Britain and elsewhere did not understand the status of the West Indies in the eyes of their inhabitants. To take Jamaica as an example, Jamaica had an area as large as Kent, Surrey, Sussex and Middlesex put together, with a community nearly as large as the population of New Zealand, which had been developing for over 250 years, and which had a deeply-founded National life of its own. A Jamaican thought of himself as a Jamaican, and as a member of the British Empire, and people who talked lightly about annexing him to the United States or to Canada entirely ignored those sentiments. The question of Federation put forward by Sir Edward was one that they could not ignore. On account of the great distances between the different islands, almost all functions of government must be local functions; a centralised West Indian Government would have very little to do. The chief functions of government in the West Indies —police, education, public health, agriculture, roads, and so on—were local functions, which even in England were undertaken by local bodies. The feeling in the islands was that there would be very little for the Executive of such a central government to do, but at the same time it would be difficult for the Governors or officials of the various islands to spare the time to attend to or take part in a central government—they were on full-time jobs already. He thought that if a High Commissioner, together with a Council, was appointed, he should spend his time visiting the different islands and studying their problems, and not undertake the governing of them, at any rate to start with. With reference to the training of teachers, there were very good colleges for that purpose at Jamaica, Trinidad and Barbados. If West Indian institutions were to be centralised, they must not all be centralised at the same place. If something was done to establish a college for training students in tropical diseases, Jamaica would probably be the best place to establish it; Jamaica could produce samples of all West Indian diseases. He looked forward to the possibility of establishing a Central Agricultural College for the West Indies, as well as a Central Training College and a Central Medical College.

The Hon. Gideon Murray, M.P., late Administrator of St. Lucia, said he had the greatest admiration for the work Sir Edward Davson had done for the West Indies during the past ten years; the paper which Sir Edward had read represented to a large extent the same views as he himself held on the present position and future development of the West Indies. Dealing with the question of federation, he thought Sir Sydney Olivier had somewhat minimised the importance of those central objects which any form of federated government might have to deal with. It was quite true to say that the majority of West Indian issues and problems must be dealt with locally in the different Colonies, but there were quite a number of important matters which could, and should, in his opinion, be relegated to some central council, which could co-ordinate them from the point of view of all the Colonies concerned; matters like steamship services, cable communication, quarantine—questions of that sort, which during his stay in the West Indies had never received the assimilated consideration which they ought to have received, owing to the fact that they were settled locally. The fact that there were not a great number of such subjects was really an argument in favour of a central government. Sir Sydney Olivier had said that the officials and business people of the various islands had not the time to attend to a central government; but if there were not many subjects to be dealt with it would only be necessary for a Federal Council to sit perhaps once a year for a fortnight or three weeks in order to consider those matters. That was the view he had come to after a residence of eight or nine years in the West Indies; and since he had left a further issue had arisen which made it even more important, in his opinion, that a Federal Council should be instituted. Sir Edward Davson had referred to the desire which had been expressed by certain people in America to take over the West Indian Islands—a desire which, he was glad to see, had been utterly and entirely squashed by the pronouncements of Lord Milner and Colonel Amery on the subject. A desire had also been expressed by a number of Canadians to form a political

union with the West Indies. Arguments against both those courses had been adduced by Sir Edward Davson and Sir Sydney Olivier, and it was unnecessary for him to repeat them; but he would like to remind the meeting that all federations in the past had been formed owing to external causes and external pressure. The reason of the federation of the Australian States was the possibility of pressure from the North, and of the Canadian States the fear of pressure from the South; and the reason for the Union of South African States was the fear of the pressure which was beginning to exert itself from Germany. The West Indies at the present time had to face that pressure, although it was being applied in a friendly way. He hoped that when the question of closer union was considered, as he understood it would be by the West Indian Associated Chambers of Commerce at their next session in Barbados in February, they would not regard it purely from the point of view of internal considerations, but would take into account the external situation. He had listened with very great interest to Colonel Amery's remarks on the development of the Empire. In Great Britain there was an increasing tendency towards the nationalisation and socialisation of everything they possessed. That was a policy which would not suit the Colonies; and he believed the only way they could develop their Colonies to-day was by utilising that good old instrument of individual and private enterprise which had proved so successful in the past in the Dominions and Colonies. He had been sorry to observe that, in the West Indies, people seemed to depend far too much on Government assistance. They ought to put more initiative and more energy into the development of their own Colonies; but besides that he would like to see capital going to the West Indies from Great Britain and from Canada, because places like British Guiana and British Honduras were only awaiting the influx of labour and capital to become the richest prizes they possessed. He suggested that the policy of the Colonial Office should be to offer every inducement to the private individual who desired to develop and to place his capital in those splendid Colonies.

Major J. A. Burdon, C.M.G., Administrator of St. Kitts and Nevis, said that of all the problems on which Sir Edward Davson had touched, he considered that of health to be the most fascinating. They all knew the old ideal of making two ears of corn grow where one grew before—or of sending two cables where only one got through before—but the highest ideal was surely to get two babies to live where one had died before, and to rid the community of crippling and preventable diseases. In the islands in which he worked—St. Kitts and Nevis—the question of improving the health conditions was exceedingly pressing, in spite of the ideal climate which prevailed. The community and the Government were not greatly to blame; scientific ideas took a long time to penetrate to the outposts, and also required a good deal of money to carry out. The infant mortality in St. Kitts, due to the ignorance of the midwives and the lower classes generally, was appalling. They had commenced to combat that by starting a maternity ward and training school for midwives, of which he had great hopes. One of the most satisfactory things about improvements in sanitation was the fact that immediate results were obtained. In several instances places that were formerly plagued by mosquitoes had been entirely cleared of them by dealing with their breeding-grounds. There were many difficulties to be met with in extending the application of that method. The rocky watercourses, where every boulder formed a potential breeding-ground after rain, and the pits which were dug at intervals along the hill roads to prevent them being washed away, were difficult to deal with; the staff required to oil them would be larger than could be provided. He was confident, however, that those difficulties would eventually be overcome, and when that was done their malaria returns would be reduced. The doctors said that every third person in St. Kitts had got filaria, but when they abolished the mosquitoes the disease would die out. He was glad to be able to state from experience that any well-considered scheme for the improvement of health received most valuable support and sympathy from the Colonial Office. That, together with the fact that men like Sir Edward Davson and Mr. Moody Stuart were advocating and working for improved health conditions in the West Indies was a tremendous encouragement to those who, like himself, were working for the same end.

The Hon. C. Clementi, C.M.G., Colonial Secretary, British Guiana, said it had been his fate to spend the last six years of his life in British Guiana, and for almost one and a half years of that period he had administered the government of the Colony. Whereas in size British Guiana was four times as great as the whole of the remainder of the West Indies, its population was six-fold less. The Colony languished for lack of fundamental requirements. Without labour and capital nothing could be done to develop the Colony. Their primary need was a larger population, but during the past five years the death-rate had actually exceeded the birth-rate, so that the population was declining instead of increasing. So long as the population of Demerara continued to reside upon coastal flats, where drainage and irrigation problems were intensely difficult, where there was no good water-supply or method of disposing of sewage, and where mosquitoes bred in millions, sanitation would be very costly. The only alternative was to encourage settlement on the highland plateaux in the interior of the country. That part of the Colony was a "white man's land," as he could testify from experience, with beautiful scenery,

abundant supplies of pure water, and a soil of considerable fertility. At present, however, there were no means of communication with that region, and to provide access would be a very costly matter. Even if steps were taken to preserve the population now resident in British Guiana, and obtain from it a natural increment, that would not suffice for a country which was as large as England, Scotland and Wales, but had only the population of Hertfordshire, and in which the area in beneficial occupation was less than one-fifth of the area of Kent. Although Great Britain had been suffering from a shortage of sugar during the past few years, on the Corentyne coast of Berbice sugar had rotted in the fields for lack of labour to deal with it. In the sugar estates of Demerara, in March last, there were 83,000 acres of uncultivated land, whereas the cultivated area was only 73,000 acres; more than half the estates' acreage was lying fallow, in spite of the world-wide demand for sugar and the high price obtainable for it, owing to shortage of labour. They had attempted to import labour from the West Indian Islands, but except in the case of Barbados—which had a population of more than 1,000 to the square mile—none could be spared. But if the whole population of Barbados was transported to Demerara, the latter would only have a population of five to the square mile. They had to look to countries where the population was hundreds of millions, and naturally turned their thoughts towards India. Negotiations had been opened with the Government of India for that purpose; if they failed, he saw little hope for Demerara in the future, and even if they succeeded it would involve British Guiana in very heavy expenses for subsidising a line of steamships between India and Guiana, and for improving the harbour at Georgetown, because owing to the bar outside it was impossible for large steamers to enter. In addition, they would require a very large loan to improve their internal communications, and the only hope he saw of raising that was for a loan to be floated in London. During the last eighty-six years the white population had decreased from 3·6 per cent. to 1·1 per cent. of the total. Given labour and capital, sugar, rice, coffee, and limes could be grown on a very extensive scale, and in the interior there were herds of cattle that could be developed. The Colony was rich in timber, gold, diamonds, and bauxite. It had great resources of water-power. There was even hope that oil might be found in the north-west of the Colony. It was his sincere hope that through the Colonial Section of the Royal Society of Arts attention might be attracted to British Guiana.

Dr. Louis W. Sambon, M.D., said that in 1913 he had the opportunity of visiting the British West Indies on behalf of the Colonial Office, for the purpose of studying pellagra. In making some remarks on the health conditions of the West Indies, he did not wish to convey a wrong impression. Although several grave diseases were prevalent, the islands were not less healthy than some of the rural districts at home. However, sanitation had been sadly neglected and disease was rampant in many of the islands. The physicians there were zealous and well-informed, but they suffered from lack of laboratory equipment, means, support, and authority. Pellagra was a disease that had been recently discovered in the West Indies and had caused some alarm, especially in Jamaica and Barbados, simply because it had not been recognised before. That disease, which was very widely spread throughout the world, had been found by him in every one of the islands of the West Indies, although possibly in some of them it might not be locally contracted. He had studied especially Barbados, Antigua and Jamaica, and there he believed he was able to locate the exact sites where the disease was endemic. From the experience he had obtained during his visit to the West Indies he had formed some impressions which had led him to make a few suggestions. The first concerned the method of tuition in regard to tropical medicine. It was now over twenty years since the London School of Tropical Medicine was founded, and as he had been a teacher there since its foundation, he had a certain amount of experience. The technique of the laboratory was taught exceedingly well, and medical men were now prepared for their work in tropical Colonies far better than those who went out before the foundation of the School. They were shown specimens of all disease agents known, and were given an excellent idea of tropical diseases from the theoretical point of view, but the School lacked the clinical material that was so valuable in the education of medical men who intended to practise in tropical countries. Therefore he had suggested that, after a preliminary course at home, students should be sent to the Colonies in order to avail themselves of the necessary material, and probably no better place could be chosen for that purpose than the West Indies. In the West Indies most tropical diseases were represented, because those islands for centuries had received a constant stream of African and, more recently, Hindu and Chinese, labourers, and because they probably represented the remnant of a land, now submerged, which at one time united Africa, Brazil, India, and even Australia, which then formed one great continent. That was very long ago, perhaps before the tertiary period, but diseases were also very ancient. When people spoke of new diseases they generally meant diseases that had not been previously recognised. The very same parasites that now existed in Egypt could be actually found by making sections of mummies of people who lived there five thousand to seven thousand years ago, and parasites that now attacked mammals and birds could be traced in the present representatives of animals that lived long before mammals and birds came into existence. Those interesting facts might, perhaps, one day, lead people into a new field of research, namely, that of the tracing of diseases back along

the paths of their migration to their cradle lands. Thus, for instance, yellow fever was found on the west coast of Africa and also on the east coast of America, and why was it found on both sides of the Atlantic? It had probably been there from time immemorial, long before the discovery of the New World by Columbus, and had possibly been there from the time when the two continents were connected. With regard to the work that he thought should be carried out in the West Indies, one of his suggestions was that a complete and thorough medical survey should be made of the Lesser Antilles. They offered exceptional opportunities for the study of questions still unsolved in tropical medicine. Being small and very different in physical features, in geological structure, in flora, in fauna, and in diseases of men, animals and plants, they provided the best possible conditions for the investigation of the etiology, œcology, and epidemiology of diseases not yet elucidated. In one island certain factors were present that were absent in another. Therefore a number of factors that were non-essential could be at once eliminated and the actual causes of, or factors in, the occurrence of the diseases thus narrowed down could be easily determined. A medical survey of the kind he had indicated would lead to a considerable advance in the knowledge of tropical medicine, and already in visiting the various islands he was able to note peculiarities in the distribution of certain diseases such as blackwater fever, yaws and pellagra, which, when worked out, should lead to important discoveries. Further, he thought one of the islands—Barbados, for instance, that was already free from malaria yaws and other diseases, but still presented some important disease scourges such as pellagra, leprosy, ankylostomiasis and filariasis—might be chosen and an endeavour be made to rid the island of those diseases. The filariasis should disappear within a few months. He need not remind those present of what had been done in the Panama Canal zone and in the island of Cuba. In the Panama Canal zone yellow fever was got rid of in about eighteen months, and malaria also was reduced to almost complete disappearance. What had been done there could be done far more easily in the Lesser Antilles. Many years ago he suggested that the white man could live perfectly well in a tropical country. It was not the heat or other climatic conditions but the parasitism of the tropics that had brought about the wilting of the white race in tropical countries. At the time his remarks had not been taken seriously; but in 1914 Surgeon-General Gorgas came to London and told them that, only posted from infection, over 10,000 white men with their wives and children lived in Panama for over ten years, continually exposed to rain and heat and every possible condition of a tropical climate, in perfect health, and what had been done there could be accomplished anywhere else.

Lieut.-Colonel Sir James Hayes Sadler, K.C.M.G., C.B., in proposing a vote of thanks to Sir Edward Davson for his most able and valuable paper, regretted that, the hour being so late, he was unable to join in the discussion. He said that he had attended many lectures and heard many papers read, but it was rarely that he had heard one in which he took a greater interest than that read on the present occasion.

Mr. Byron Brenan, C.M.G., seconded the resolution, and in doing so said he was sure the author would be immensely gratified by the fact that every one of the speakers in the discussion began his remarks by announcing how very thoroughly he appreciated the value of the paper.

The motion was carried unanimously, and, the author having briefly replied, the meeting terminated.

COMMERCIAL POSSIBILITIES OF RIO HACHA DISTRICT, COLOMBIA.

Rio Hacha is situated near the Calancala River, on the boundary between the Province of Padilla, of which it is the capital, and the Goajira Peninsula. It is one of the oldest towns in Colombia, but little remains of the old Spanish buildings. There is no harbour, the sea being an open roadstead and very shallow, even small sailing vessels having to anchor at a distance of 1,000 yards from the beach; cargo is handled by means of small "cayucos" or large dug-out canoes. The lands in the interior are semi-arid, but subject to floods during excessive rainy seasons, the country being practically level, with little high ground.

From a report by the United States Trade Commissioner at Santa Marta on the commercial possibilities of the Rio Hacha district, it appears that there are extensive areas covered with a species of wild "magney," described as nature-sown plantations. The fibre is utilised by the Indians in making hammocks, and is of a finer quality than the "fique" of the interior. Samples have been submitted to Professor Dewey, fibre expert of the United States Department of Agriculture, who classifies this plant as *Furcraea macrophylla* and says that samples indicate that the fibre is finer, whiter, and softer than that either of the true sisal or the henequen of Yucatan. So far as is known, no fibre from these wild plants has been produced commercially. According to Professor Dawe, Agricultural Adviser to the Colombian Government, the possibilities of developing a new and important industry in this district appear to be very favourable.

The lands in the region of the Calancala River, excepting parts which are subject to overflow in the rainy season, are on the whole suitable for fibre cultivation. The situation of these lands is also favourable, being only four or five miles from the town of Rio Hacha. They are almost level or slightly undulating. The special recommendation lies in the fact that there is already a sufficient

supply for cutting, so that extraction could be begun as soon as machinery was installed. Cheap labour is obtainable, and the Calancala River would furnish ample water-power.

The aloe plant, which requires a dry soil, is found growing wild in the Goajira Peninsula. Near Rio Hacha there is a small aloe plantation, privately owned, which exported in 1915 about 500 lb. of extract, and in the first six months of 1916 over 1,000 lb. The leaves are ripe for the extraction of the drug in the dry season, when they assume a coloured hue.

The coast lands of the peninsula near Castilletes contain rich deposits of talc, which are being worked for export to Venezuela, its local value being about 16s. 8*d*. per ton. It is thought that more remunerative prices could be obtained in the United States, but lack of transportation has prohibited anything being done in this direction.

The Goajira Peninsula contains the principal supply of divi-divi in Colombia. The tree grows in the north-west part in the sandy lands along the coast.

The principal wealth of the north-western part of the peninsula lies in salt, salinas occurring along the coast practically throughout its whole extent. It is said that these salinas are capable of producing a million sacks annually. The present production is limited, owing to the fact that there are other salinas nearer to the centres of consumption, such as those near Barranquilla and at Santa Marta.

A new product found in the Rio Hacha district is known as "qüika" resin. This is produced by a small tree (*Cercidium spinosum*) (Tulsane) whose trunk and branches, and even roots when exposed to the air, are covered with a layer of resin. A single tree yields several pounds, and as the growth is very abundant in certain parts it should prove a valuable article for export. Samples have been sent to Europe and the United States for examination and report.

El Portete and Bahia Honda have been mentioned as new seaports for the Goajira Peninsula, with plans for a railway running south into the Valle de Upar district. Such a railway would tap the copper and coal deposits of the Villanueva region, as well as open the peninsula to agriculture and cattle-raising. This route is also attractive because it is the best one to Bogotá, the higher and more difficult ranges of the Andes being avoided.

MANUFACTURE OF ANGOSTURA BITTERS IN TRINIDAD.

One of the most important industries of Trinidad is the manufacture of Angostura bitters, the island having a monopoly of this speciality, which is exported to all parts of the world. In 1917 the United Kingdom, despite difficulties of sea carriage, took 10,534 gallons of bitters, and the United States 9,397 gallons, out of a total quantity exported of 22,667 gallons, valued at some £24,000.

According to a report by the United States Consul at Port of Spain, the inventor of Angostura bitters was Dr. Johann Siegert, who was born in Silesia in 1796. He went to Venezuela in 1820, finally settling in Angostura (now known as Ciudad Bolivar), on the Orinoco River, where he practised as a physician and devoted special attention to the study of tropical herbs and plants having medicinal value.

In 1824 Dr. Siegert prepared for his own use what he called "aromatic bitters," but, as they acquired much favour among his friends and the public, in 1830 he began to manufacture the bitters on a commercial scale, the first export to England taking place in that year. The bitters became known to the trade as "Angostura," from the name of the town on the Orinoco River where they were first made. On account of political disturbances in Venezuela the place of manufacture was changed in 1875 to Port of Spain, Trinidad. The present manufacture is controlled by a limited company, with an office in London.

Angostura bitters are made after a secret formula, which has been carefully guarded by the descendants and successors of Dr. Siegert, and the preparation apparently has never been successfully imitated since its invention in 1824. The concoction is understood to consist of a mixture of certain bitter aromatic and carminative substances, with alcohol added as a preservative and solvent. It has its most important use as a medicinal agent, but its best known use is as an ingredient in cocktails of all kinds. It is now much used also to flavour such temperance beverages as lemonade, ginger beer, ginger ale, and even mineral waters, and is occasionally added to fruit syrups, Christmas puddings, and mincemeat.

A temperance beverage popular in the West Indies, and one much used in the treatment of various tropical maladies, is Angostura barley water, made by adding a dash of bitters to a teaspoonful of barley, the juice of one lime, two tablespoonsful of granulated sugar, and two pints of boiling water. The chief medicinal value of the bitters is for fevers, ague, dysentery, cholera, and other intestinal troubles, and as a tonic.

Over half a million glass bottles are required in Trinidad every year in connection with the manufacture and export of Angostura bitters. Before the war these bottles were imported from Germany, but since 1914 they have been obtained from the United States, and great difficulty has been experienced in securing a sufficient supply of them to maintain the export trade in the bitters. The bottles are fitted with spray or sprinkler stoppers. The partners and managers of the business in Port of Spain personally do all the work of compounding the bitters, and only the work of filling the bottles and packing the cases is performed by their employees.

In Trinidad, in addition to the manufacture of Angostura bitters, there is a large production of various cocktail preparations, punches, swizzles, etc., in which the bitters appear as a flavouring ingredient, but cane rum, lime juice, sugar, and indigenous herbs of the West Indies and Venezuela

make up their main substance. Trinidad, indeed, seems to be the original home of the cocktail, and visitors there are amazed at the great number of different drinks which are served. (Even at church fairs and entertainments cocktails are offered at special bars.) However, the locally manufactured preparations, with the exception of bitters alone, are seldom exported, as the freight costs and import duties on such preparations are too heavy to make their shipment profitable ; and as rum, sugar, etc., can be readily obtained elsewhere, the cocktails can be made more easily and cheaply in the countries where they are consumed than the original beverages can be imported in bottled form from Trinidad.

THE COFFEE INDUSTRY IN PANAMA.

Panama presents a very favourable field for the growing of coffee, and there is quite a colony of foreigners, mostly Americans, situated in the district of Boquete, Province of Chiriqui, engaged in the industry; but the coffee lands of Boquete are limited and nearly all the good land is occupied. The best district for the raising of coffee is situated in the uplands of the district of Bugaba, where vast areas of the very best lands for coffee-growing exist and where climatic and other conditions are most favourable to its growth.

Coffee from this section is classified as the best in the world's market. Grown at an elevation of from 2,000 to 5,000 feet, it not only reaches perfection, but the altitude provides a healthy, cool, salubrious climate which cannot be excelled, the temperature ranging from 60° to 75° F. all the year round.

Boquete is the terminal for the national railway, and Concepcion, the capital of the Bugaba district, is the terminal of a branch of the same railway which provides transportation to the port of David, whence all products are shipped to Panama City.

After selecting a suitable piece of land, the timber is felled and generally burned, then the land is lined off and the young coffee trees are transplanted from a nursery which has been previously prepared, or with trees brought from a nursery. To prepare a nursery, the ground is properly cleared and the coffee berries are planted about six inches apart; in a few weeks the plants begin to show above ground. They may be transplanted at a year old, but generally at two years, after which they require two years to begin bearing, and at four years are in full bearing, averaging 3 lb. per tree. No shade is required in Panama, and the only cultivation consists in three or four cleanings a year to keep down the weeds, as no ploughing, etc., is necessary.

From a report furnished by the United States Consul-General at Panama City, it appears that coffee in Panama matures from October to January, and is then picked and taken to the factory, where it is fermented, after which it passes to the pulper where the outside hull is removed; then it is washed and dried, either by the sun or in patent driers. It is now known as pergamino, each bean being encased in a thin shell, which is removed by a sheller; it is then graded and bagged, ready for market. Water-power being abundant, this is used for running all the machinery, which is simple and requires no expert to operate it.

The annual output of the Province of Chiriqui, which produces the bulk of the coffee, is approximately 4,000 sacks of 100 lb. each, all of which is produced in the Boquete at present, as the coffee planted in the Bugaba section is still young and unproductive. The local supply does not meet the domestic demand, and instead of there being an export trade, a great deal is imported from adjoining countries.

Labour is plentiful and is paid at the rate of one dollar per day. Most of the work is done by contract. The cost of bringing a coffee plantation into bearing is about 70 cents per tree, and it is then valued at one dollar. This cost includes land, cleaning, felling timber, nursery, transplanting, and care. Most of the timber may be used for lumber, which commands a good price, as well as for the construction of all buildings. Catch crops may be planted between the trees the first two years. The climate is exceptionally healthful and the soil will produce anything planted, products of the temperate and torrid zones thriving side by side. In good soil 400 trees may be planted to the acre. The annual cost of maintenance is about 10 dollars per acre.

CORRESPONDENCE.

POWER FROM THE SUN.

The following letter is reprinted from *Nature* of December 18th:—

In the very interesting Trueman Wood Lecture delivered at the Royal Society of Arts on December 10th, Sir Oliver Lodge discussed the utilisation of solar radiation, and recommended, as the best method of effecting this purpose, the promotion of agriculture of every kind. According to Sir Oliver Lodge, the green leaves of trees and vegetables generally are able to absorb and utilise solar energy without much regard for any hampering limit to efficiency such as the second law of thermodynamics, but in saying this he appears to be unaware of the researches of Dr. Horace Brown, who has shown that the actual amount of energy stored is less than 2 per cent. of that which reaches the vegetation.

Now the total amount of solar energy intercepted by the earth is prodigious, being in the aggregate some 200 billion h.p., or, on an average, about 4,000,000 h.p. per square mile of that portion of the earth's surface that is exposed not too obliquely to the sun's rays. Absorption by the clouds and by the atmosphere, though important, is not so great as might be expected, with the result that even in this latitude and in this climate the energy

constantly received throughout the hours of daylight exceeds 1,000 h.p. per acre.

If, then, some method could only be devised for efficiently converting this energy into a form in which it could be readily applied for motive power and other purposes, the gain and the convenience would be enormous; for, to take a single instance, sufficient energy to run all the machinery in a factory throughout the working day could be collected from an area in many cases not greater than that subtended by the factory's roof.

Now, of course, for reasons which Sir Oliver Lodge fully discussed, it is hopeless to expect to be able to effect anything of this nature with the heat engine, for with this we should scarcely reach the 2 per cent. efficiency nearly attained by vegetation. But is there any need to allow the radiation to turn itself into heat at all? Solar radiation, as is well known, consists of electromagnetic waves in the æther—waves exactly similar in kind to those employed in wireless telegraphy. The only difference is that, whereas the length of the waves used in wireless telegraphy is a matter of hundreds or thousands of metres, the wave-length in the case of solar radiation is only a very minute fraction of a millimetre.

Even with wireless waves the resulting frequency is too great to allow of the electric currents they induce being directly utilised. The telephones and other instruments employed offer too much impedance to allow such currents to pass, while apart from this, no mechanical device could move with sufficient rapidity to respond to such frequencies. In wireless telegraphy, however, a method has been devised for converting these rapidly alternating or oscillating electric currents into currents which, though pulsating, are unidirectional. This is accomplished by the application of thermionic or crystal rectifiers or non-return valves, which only allow the currents in one direction to pass and suppress altogether the currents in the opposite direction. In this way the comparatively useless high-frequency oscillatory currents are converted into rapidly pulsating unidirectional currents which behave like continuous currents, and will operate telephones and other electromagnetic devices. Moreover, though in wireless telegraphy it is customary to use the currents in a single direction only, and to suppress the inverse currents altogether, there is no difficulty about utilising both currents by turning them into separate circuits with valves set opposite ways. Under such conditions, seeing that the separate valves let through their respective currents with but little loss, the efficiency of the conversion from the radiant energy absorbed to that utilisable in the form of electric current is quite high, probably not less than 50 per cent., and perhaps considerably more.

Is it too rash to suggest the possibility of some analogous method being applicable to convert into utilisable electric currents the electromagnetic waves of which the radiant energy from the sun consists? The method is quite successful with wireless waves having frequencies of millions per second, but can it be applied to the sun's waves, the frequency per second of which is of the order of billions? No doubt the problem is a difficult one, but we live in an age of marvels, and what would have been said of modern wireless methods only a few years ago?

One thing seems certain. The energy in the sun's radiation is there, and there, too, in most abundant quantity. To make use of it, moreover, requires no Maxwellian "demon" such as is necessary to render available the general stock of heat energy at uniform temperature. Nor, again, does what is suggested run counter to any thermodynamical law such as would preclude full advantage being taken of the great efficiency that is rendered possible by the enormous temperature of the sun.

Anyway, the problem of the application of solar radiation to the production of power otherwise than by means of heat engines seems worthy of attention, and is a problem that would appear much more likely to meet with a speedy solution than the difficult and obscure question of the liberation and utilisation of the internal energy of the atom.

NOTES ON BOOKS.

COLOUR AND HEALTH: a Symposium. Edited by the Rev. John J. Pool, Ph.D., B.Sc. London: Cope & Fenwick.

To any informed person the abuse of colour in our homes and factories is little short of amazing. While attention is deservedly given to the technical quality and lasting value of the actual pigments and other applied decorations, a comparatively small amount of thought is lavished upon the value of the colour as colour. Only within quite recent years has a general appreciation of the value of the lighter coloured pigments arisen, with regard to their reflecting qualities for factory use, and as affording a chance of considerably reducing the lighting bill.

The finer intricacies of expert scientific factory management must inevitably lead the works manager to make at least some study of the finer questions regarding the value of environment in terms of colour, and for this purpose no better book could be recommended than "Colour and Health," a symposium by ten expert writers on various phases of colour, edited by the Rev. Dr. John J. Pool, Principal of the International College of Chromatics, which was instituted for the study of colour in 1916, at 3, Finsbury Square, and is the only institution of its kind in the world.

The facts of the medical use of colour, both for common mental cases as well as for the disorders arising from the war, are aptly quoted as affording evidence of the remarkable power of rightly used colour, whether as sedative or as stimulant. But

equally important is the fact, which the book does not stress as it easily might, that colour can also be used in ordinary life as a factor of actual value in commercial production. As speed in workshops necessarily depends on the fatigue ratios of the operatives' vision, it is obvious that the correct selection of colours and adjacent lighting will become an important factor. Which colours to select can be found in this volume. This is quite apart from the usual psychological value of colour, dealing with the mental energies of the human brain, for this system of colour selection impinges upon the emotional side, and has a subconscious and *continual* action upon the subject, while the other demands an act of attention to be of use.

In the present re-valuation of scientific principles, the vastly important facts of light and colour will not escape testing, and the business man of wide vision will lend a ready ear to those expert pioneers whose experiments have had such remarkable success. W. G. R.

GENERAL NOTES.

Sir William Duke. — Sir William Duke, G.C.I.E., K.C.S.I., has been appointed to succeed Sir Thomas Holderness, G.C.B., K.C.S.I., as Permanent Under-Secretary of State for India, and will take charge of his new post on January 1st, 1920. Sir William has been a Vice-President of the Royal Society of Arts and Chairman of the Indian Section Committee since June, 1916.

Barcelona International Fair.—An International Fair is to be held at Barcelona from May 15th to 30th, 1920, and in each succeeding year. Exhibitors must be producers, manufacturers, wholesale dealers, etc. Retailers and resellers are not admitted, and it is absolutely prohibited to sell retail or to deliver goods in the grounds of the Fair. Exhibitors can only book orders. Exhibits are divided into groups representing agriculture, horticulture, medicine, chemicals, mining, engineering, electricity, building construction and decoration, textiles, artistic industries, cutlery, jewellery, brush and toy making, etc. Exhibitors will have the benefit of facilities for transport and of modified customs duties. Application for certificates of admission and details of transport, customs duties, etc., should be addressed to La Direccion General de la Feria de Barcelona, Fernando 30, Barcelona, before January 15th.

Einstein's Theory: Seminar at Toynbee Hall.—The present verification of Einstein's theory of space and time has attracted the attention of those interested in scientific theory. It has been impossible, within the limitations of the press, to convey to the public what this theory implies. To meet the need felt to an increasing extent by a number of science teachers and advanced students for a deeper understanding of the principles underlying physical science, and especially the methods by which such principles are being formulated, Dr. S. J. Plimpton and Dr. F. S. Goucher, who are at present engaged in research work under the University of London and the Committee of the Privy Council for Scientific and Industrial Research, will hold a weekly evening seminar at Toynbee Hall during the winter, if it is clear that a sufficient number would like to attend such a course. It is not intended merely to cover the ground already undertaken by various technical institutions or to popularise the subject, but to present the philosophical and experimental processes by which progress in physical science is being made. The detailed form which the lectures will take will be determined to a large extent by the course of events and the progress made, but the course is intended to deal with dynamics, thermo-dynamics, electro-dynamics, the electron theory, the ether concept, principle of relativity, the quantum theory, and automic structure. Any who are interested should write stating the extent of their interest and their qualifications to the Registrar, Toynbee Hall, 28, Commercial Street, E. (1), and arrangements will then be made for a preliminary discussion between intending students and the teachers.

British Aircraft Competitions, 1920. — In connection with the British Aircraft Competitions for prizes amounting to £64,000, the following list of engines for use by competitors has been approved by the Air Council:—A.B.C. (all types), Boardmore (160 h.p.), B.H.P., B.R. 1, B.R. 2, Cosmos (all types), Galloway Adriatic, Galloway Atlantic, Galloway Pacific, Green (all types), Napier Lion, R.A.F. (all types), Rolls-Royce (all types), Siddeley Puma, Sunbeam (all types), Wolseley Viper. It will be left to the discretion of the judges to decide whether any new engine not included in the above list fulfils the conditions of the competition. The competitions will commence on the following dates:—Aeroplanes, small type, March 1st, 1920; aeroplanes, large type, September 1st, 1920; seaplanes (amphibians), August 1st, 1920.

Depth-sounding by Explosive Charges.—Some of the methods employed in the Navy for sounding the depth of the sea by means of explosive charges were recently described in *Le Génie Civil*. A small explosive charge is detonated in the water close to the vessel in motion. A microphone immersed to a slight depth and fixed to the boat at a known distance from the point of explosion first collects the detonation and then the echo reflected from the bottom of the sea. These two sounds are recorded on a chronograph, which permits the interval of time separating the two sounds to be read with great accuracy. The time interval and the mean speed of sound in the water being known, a simple formula gives the depth of the water. Experiments carried out in the Channel at depths between 60 and 100 metres gave very satisfactory results.

Journal of the Royal Society of Arts.

No. 3,502. VOL. LXVIII.

FRIDAY, JANUARY 2, 1920.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

Wednesday, January 7th, at 3 p.m. (Juvenile Lecture.) Mr. Loughnan Pendred, M.I.Mech.E., Editor of *The Engineer*, "Railways and Engines." (Lecture I.)

The lecture will be fully illustrated with working models and lantern-slides.

Special tickets are required for the Juvenile Lectures, and no person can be admitted without one.

Further particulars of the Society's meetings will be found at the end of this number.

LIST OF FELLOWS.

The new edition of the List of Fellows of the Society is now ready, and copies can be obtained on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

FIFTH ORDINARY MEETING.

Wednesday, December 17th, 1919; Sir Henry Trueman Wood, Chairman of the Council, in the chair.

The Chairman, in introducing the reader of the paper, said Mr. Grunwald was a Russian who had lived in Russia all his life, and had an intimate acquaintance with its resources and industries. He had been one of the chief officials of the Russian Ministry of Trade, and since the war had been the principal organiser of the association which had been formed in London by Russian leaders of industry, and which was endeavouring to reorganise the trade of their country, so that when the happy time arrived when peace was at last established they would not be wholly unprepared. The paper dealt exclusively with industrial and economic matters, as the Royal Society of Arts was not the place for political subjects. He was sure those who took part in the discussion would bear that in mind.

The paper read was—

THE PRESENT ECONOMIC POSITION OF RUSSIA AND SOME ASPECTS OF ITS FUTURE DEVELOPMENT.

By Constantine Grunwald,

General Secretary to the Russian Manufacturers' and Merchants' Association in London, and late Chief of Intelligence Department, Russian Ministry of Trade, Petrograd.

It is rather a difficult thing to speak nowadays about Russia. The Russian problem has, unluckily, become a question of internal party politics, in this country as elsewhere; and if you treat the problem from the purely political point of view you get immediately entangled in a muddle of party interests and passions. If, again, you try to consider the events of Russia from a military point of view, you will come unavoidably to false conclusions. The civil war raging at the present time on the vast plains of the former Russian Empire, cannot be judged by experiences won in the late world-war struggle. Besides, one must necessarily agree with those who say that Bolshevism cannot be destroyed by the force of arms alone, and that ideas, however wrong they may be, cannot be killed by bullets. Finally, if one were asked to give nothing but practical advice to City business men interested in Russian affairs, one would find oneself confronted with great responsibilities as, under the actual position of Russia, it is rather difficult to expect the speedy realisation of great profits or revenues.

Still, I am indebted to the Royal Society for the Encouragement of Arts, Manufactures, and Commerce, for giving me this occasion to discuss before you the position of my country. Here, in this historic hall, I am able to take up the Russian question from an entirely impartial and broad point of view, as a problem of culture and economics, as a problem that does not

admit an immediate and full solution, but deserves close study and earnest appreciation.

To understand the present, it is always useful to go a little back in the past. In an old country like Great Britain, changes in the political and social structure come very gradually and in an almost imperceptible way. The development of a young country like Russia can be compared to the growth of a child—you do not recognise it if you have not seen it for a few years. That, by the way, explains why we have heard such contradictory opinions about Russia from people, and even very expert people, who have visited the country during different stages of her recent development; and it is needless to explain that, during the war and the revolutionary period, the quickness and briskness of those transformations have assumed an almost catastrophical character.

If you judge about Russian affairs, you must never forget that only some fifty-seven years ago the great bulk of the Russian nation was delivered from the bonds of a serfdom which amounted to something not very far removed from slavery. At that time Russia, from the point of view of economics, was a country living exclusively on agriculture of a primitive character, and furnishing to the world market nothing but the produce of farming or hunting. Only in the later part of the nineteenth century we see the birth of Russian industry and its rise by leaps and bounds. First of all there is the wonderful development of the cotton industry in the Moscow district—its pioneers were your countrymen from Lancashire. Then, simultaneously with the construction of the railways, comes the moment for the metallurgical industry in the Urals, and especially in the so-called Donetz district in the South Russian Steppes, between the Don and the Dniester. Then again, in the eighties, rises suddenly, like a mushroom, the cotton industry in the Lodz district, now belonging to Poland, and started mainly by German energy.

During the last years of the century the great statesman, Count Serge Witte, brought system into the industrial evolution of Russia, and led her with a firm hand towards an economic development in a purely West European sense. The foundation of a solid monetary system, a great railway construction scheme, the opening of Siberia, the influx of milliards of French and Belgian capital to the South Russian industry, a broad exploitation of the Baku oil fields, the appearance of Russia as the furnisher of manufactured products on the world markets of the Near, Middle, and Far East, are some aspects of the great work accomplished in the epoch of Witte.

Then, finally, after the first revolution of 1905, came a new and very interesting period in the economic life of Russia. Being aware that a chief reason of the political discontent lay in the poor material condition of the peasant class, the Government, led by Stolypin and Krivoshein, started a big scheme of agrarian reform by creating private ownership on peasant land, which was up till then in communal possession. This led to a very great increase of productivity in agriculture and farming. The amount of agricultural machinery sold in 1895 was 20 million roubles, in 1912 it was 110 million roubles. The value of grain production rose, in the same period, from one to four milliards. In the year preceding the war, the Department of Agriculture spent 30 million roubles for developing agricultural productivity—a larger sum than was spent by the Board for the entire period of forty-five years from 1838 to 1882. The butter export from Siberia, amounting to some 2,500 tons in 1898, was ten years later increased to 40,000 tons. However one may judge about the old Russian régime now overthrown by the revolution, it is hardly possible to deny that, in the domain of purely economical activity, it has done a tremendous work in developing the sleeping productive forces of the great empire. And it is certain that, on the eve of the war, Russia was at the beginning of a great ascending movement which, as some thought, might even have led her to a peaceful and gradual change from her antiquated political conditions.

But, of course, it was only a beginning. The great distances, the hard climate, the ignorance of the masses, were only some of the obstacles which prevented Russia from growing so quickly as to bear comparison with other more fortunate countries.

On January 1st, 1915, the length of Russian railways of general importance was about 50,000 miles, of which only 6.744 miles were in Siberia. The United States had in 1913 a railway system of over 266,000 miles; the population of the United States is, roughly, 97,420,000, and its area is 2,973,000 square miles. In other words, the United States, with a population, roughly, of only one-half, and an area of only one-third of the Russian Empire, has more than five times the mileage of railways. The *per capita* consumption of iron in Russia was considerably behind that of the other

European countries. While for Germany this amount was 319·8 lb., for Great Britain 269·1 lb., for France 245·7 lb., the corresponding figure for Russia was even in the record year, only 62·4 lb. The number of joint-stock companies in Russia barely reached 2,000, while England had more than 56,000. And even in agriculture Russia was far behind the other countries on the world market. The annual average yield of wheat per acre in bushels (1907–1913), was 10 for Russia, 14·4 for the United States, 16·8 for Rumania, 19·2 for Canada. Only Argentina approached the Russian level with 10·6 bushels per acre.* Finally, I should note that the number of men working in industry throughout the whole great country, with a population of 150 millions, was not more than 7 millions.

All these statistics prove the conclusion we arrived at beforehand, that Russia was just starting her industrial development. The capitalistic class was only in the stage of formation, the fate of the old Imperial Russia was ruled by a class of great landowners, officers, and noblemen, together with the so-called intellectual classes, both of them very far away from the great mass of the nation, and still farther from commercial and industrial interests. In this Russia grew up the brilliant literature that most of you know from the books of our world famous writers, the Russian opera music, and also the Russian ballet which now appear before me on the stages of this city like shadows of a long bygone past.

War and revolution have for ever stopped this whole period of Russian life. In Russia, as elsewhere, the immediate consequence of war was the mobilisation of millions of the best and strongest workers, an extremely intense exploitation of railways without regard to the necessary repairs (every wagon had to work about 40 per cent. more than in normal times); and thirdly, an inundation of the country by a flood of milliards of paper money. From about 1 milliard 700 million of roubles, the amount of paper currency had risen, on the eve of the revolution, to 17 milliards. The dangerous consequences of that phenomenon showed itself in Russia, just as in other places, only in the later period of the war. In the beginning the outlook was rather bright; first it looked as if war was going to make everybody wealthier; the mobilisation of industry, the storing of huge stocks of farm produce and grain for the army, gave to the manufacturers, as well as to the peasants, considerable profits which were, as a matter of fact, made illusory by the growing cost of production and living, and a gradual depreciation of the currency. Already from 1913 to 1915 the price of produce of the first necessity had risen by 53 per cent., the salaries only by 19 per cent. The normal production of a workman in the mining industry of South Russia had fallen, in the third year of the war, by 50 per cent., owing to the substitution of female and prison labour for the former stronger element. The want of a free outlet to the sea stopped the Russian export trade, and disturbed in a radical way the position of the Russian trade balance which was formerly excellent. The State revenues suffered heavily from the abolition of the spirits monopoly, which ranked formerly as the first item of the budget, and gave to the Government up to 80 million pounds a year. Last, but not least, a certain demoralisation, inevitable in wartime, spread itself widely between the capitalist and working-classes, awaking the spirit of profiteering known well enough in Western Europe.

The things I am telling about must be well known to your own experience. But how much more disastrous must have been the result in a country which was, as I have just said, at the beginning of her economic development! And it was on such ground—primitive in itself, shattered and loosened by the consequences of war—that the leaders of Bolshevism started, after returning from their exile at the moment of the revolution, the most daring of all economic experiments known to the world's history. I consider that British public opinion gets quite a considerable amount of information about the state of affairs in Soviet Russia. Some three or four weeks ago, looking through the morning press, I was sometimes inclined to think that I was living on the shores of the Neva and not on the Thames—nothing but Russia all round. And still I daresay there is a point which is not made clear enough to the public, which reads all about the atrocities of Bolshevik executioners and Red Guards, or about the amenities of the new proletarian paradise supposed to be created by Lenin and Trotsky. It is the consideration that Bolshevism is not so much a political as an economic creed. For one who has studied the theoretic foundation of Bolshevism, it is perfectly clear that Bolshevism means nothing else than an immediate and full application of the economic programme of Karl Marx. We have

* Dr. Joseph M. Goldstein's "Russia." (New York, 1919.)

been sometimes told, although I find it hard to believe, that the Bolshevists would be inclined to call for a Constituent Assembly of the Russian people. But I have never heard, and certainly will never hear anything, about even a partial revocation of this programme of nationalisation and State socialism, which is the essence of Bolshevist rule, and which has brought to Russia ruin and desolation. The question of nationalisation is an up-to-date problem in Great Britain too, and it is not for me to say how it will be solved in due time; but I know that nobody, even of the most advanced Labour leaders, has ever suggested the converting with one stroke of the pen, into State property and without any remuneration to the actual proprietors, of all the banking, industrial and commercial interests of the country—and that is what has happened in Soviet Russia in the first months of the Soviet régime. The High Council for National Economy, a beaureaucratic institution led by theoretical fanatics and ignorant labour men, is supposed to run in Soviet Russia the whole work of industrial production and distribution of internal and foreign trade, which is done elsewhere by the efforts of the private initiative and energy of tens of thousands of managers, directors and proprietors of individual firms. There has been talk recently of the possibility of raising the blockade, and the last session of the Trade Union Congress has pointed to the possibility of getting from Soviet Russia large amounts of various raw materials of great value for this country. Now the raising of the blockade might possibly be necessary from the political point of view—I have my opinion about it, but would prefer not to mention it. But I must say that the hope that this measure might open any possibility of exploiting the Russian market can be based only on an unconscious and possibly even conscious distortion of facts. With the best will in the world I cannot understand how the British merchant will carry out his operations in a country where private property is not recognised, and how the Bolshevik authorities may be able to fulfil their engagements and contracts when, up to the present, they have not succeeded in satisfying more than 5 per cent. of the normal consumption of the interior market.

The question of the practical results of the nationalisation scheme in Soviet Russia is an extremely interesting one; but time does not allow me to speak about it at satisfactory length. I must be content to draw your attention to a very impartial and well documented article of Mr. Robert Crosier Long in the November number of the *Fortnightly Review*. He will tell you that the deficit of the Bolshevik Budget for each month amounts to 60 milliards of roubles, and the loss from the nationalised industries another 10 milliards; that a branch of industry which paid in a single year 648 millions of wages has produced manufactured goods for 143 millions; how the scheme elaborated for distribution among the peasants of 600 million roubles of goods in the month led in reality to the distribution of goods for 75 million of roubles. I can only refer to the conclusion of Mr. Long that "regarded from all economical standpoints—volume of production, rate of employment, prices, and profits or losses—nationalisation has failed." And this is a conclusion which is confirmed by the experience of all who have lived, as I have, for a year or more, in Soviet Russia, and not only gone over to Moscow for a week-end journey. And as this nationalisation scheme is the essence of the Bolshevik system we can say without exaggeration that Bolshevism is slowly but surely approaching its final dissolution—a conviction shared by Lenin himself as he said that only a world social revolution can save Soviet rule. The much talked of Mr. Litvinoff confirmed the same thing a few days ago in Copenhagen. But, needless to say, the experiment made by Bolshevist vivisectors on the body as well as on the soul of Russia, was bound to give the saddest result in the actual economic position of that country. Everybody knows that Petrograd is suffering from real starvation, but the greatest scarcity is seen just as well in other towns even when they are nearer to the centres of production. Where there is grain there is lack of manufactured products. On July 1st they were paying in Moscow for a box of matches up to five roubles, for a pound of nails 800 roubles. The position of the railway transport is illustrated by the following statistics: the percentage of locomotives awaiting repair, which in 1913 was 16, was lately reported to be 47·7. Another report says that of 8,971 locomotives in Soviet Russia 4,728 need repair. The percentage of cars awaiting repair was in 1913, 3; in 1919, 16·6. The railway collapse is not due to financial cheeseparing; the expenditure rose from 705,000,000 roubles in 1913, to 7,300,000,000 roubles in 1918, and a profit of 470,000,000 roubles was turned into a loss of 5,500,000,000 roubles. And as to wages, the workman who formerly received some 50 roubles per month earns now 1,000 roubles,

but is certainly not better off than he was before.

The general aspect of these figures is such a gloomy one that they would really give reason to despair if they gave an entirely true picture of the actual economic position of Russia. Happily this is not the case. The normal instincts of healthy economic activity make way for themselves in spite of Lenin and his Supreme Economic Council. The greater part of Bolshevist legislation remains on paper. Read Calderon's comedy, "Life is a Dream," and you will easily find the analogy between Lenin and the hero of this play, who fancies for twenty-four hours that he is a king. When, as I told you before, the Bolsheviks' administrative machinery is able to satisfy only 5 per cent. of the normal consumption, you must not imagine that 95 per cent. remain unsatisfied. The population gets supplies—of course very much reduced—in an illegal way. You cannot get nails in the Soviet shop, but a boy will be standing outside in the street offering you those same nails in a surreptitious way, and this boy is, as a matter of fact, the clerk of a great commercial organisation spreading all over the town, and conducting a secret trade in this or that article. Hundreds and thousands, if not millions of peasants, attracted by high profits, carry sacks containing farm produce to the great consumption centres literally by the sweat of their brows, and that is the strange result of this Government monopoly of every trade, that it creates this new very enterprising and energetic class of men who are to-day "sack bearers" but will be traders to-morrow. The Soviet people send around in the village districts pamphlets about the obnoxious activity of these capitalistic joint-stock companies, and the peasant who has never heard of such an institution before says, "That's a good thing; I should like to have some shares," and makes a contract with the owner of a mill, converting it for the moment into a communistic socialistic property bound in due time, when the Bolshevists are gone, to be further converted into a joint-stock company. And so, after all, the fight against capitalism, which was more or less non-existent in Russia, creates interest for capitalism and possibly a new class of small capitalists.

And then there is another thing that should never be forgotten. The Bolsheviks have never been the rulers of the whole of Russia. In spite of their recent military successes, even now half of Siberia, the western boundaries of Russia—with all the newly-formed States—and practically the whole south of the country together with the Black Sea shore are not in their power. And to understand the economic importance of South Russia it should be remembered that its exports include one-third of the total Russian grain production, five-sixths of the sugar production, one-third of the meat production, 70 per cent. of the coal production, and 60 per cent. of the pig-iron.

Of course, in all those territories the more or less prolonged invasions of Bolshevik armies and the subsequent state of civil war have left very deep traces. The saddest of all this is that it has slackened the respect for honest work as well as the feeling of responsibility of the individual to the State and society. The second symptom is the extraordinary position of the rate of exchange; a pound sterling that was worth nine roubles before the war, and a hundred roubles this spring, is now exchanged for 800 or 1,000 roubles. The prices of all commodities are extremely high. In Tangarog they paid in the beginning of November for a yard of woollen cloth about 600 roubles, for Cheviot tweed 1,200 roubles, for officer's boots not under 3,400 roubles, for butter 100 roubles per pound, for bread 5·50 per pound, for eggs six roubles a piece. This district seems to me to be in a rather disadvantageous position; in Rostoff the prices may be about 50 per cent. lower, but even this is a very poor consolation. The root of all these evils is the very bad condition of the railways, the lack of repairing materials for the rolling-stock, the bridges and so on, and the subsequent possibility of transferring the merchandise to the ports and consumption areas. I think that many of the Englishmen who have recently gone to South Russia have been too strongly impressed by all those facts. I do not conceal them from you, but I want you also to look at the other side of the medal. Private property and legal security are re-established in Southern Russia. The country has had the benefit of a harvest that has been a record for the last thirty years. There is unanimity in stating that from 10 to 15 million tons are available for export only. The coal mines are exploited, owing to the lack of transport facilities, only to 25 per cent. of their normal production, and give now not more than one million tons a month. Any increase of the production can give huge quantities for export, and the same is true of iron ore. I should think that the extreme scarcity of these products in Western Europe should prove in itself a sufficient reason to

undertake the most heroic measures for re-establishing a normal economic activity in Southern Russia. And if General Denikin has up to the present not entirely succeeded in achieving his great task, it must be borne in mind that he began as chief of a great military organisation which wished to postpone the question of government and interior reorganisation on broad lines up to the moment when the Bolshevik régime would be overthrown. By this time it is clear that the task is not so easy as it seemed to be. The economic theories of the Bolsheviks, based on theoretical and abstract principles, must find themselves confronted with other economical programs, dictated by practical considerations and a real knowledge of the needs and resources of Russia. And the day that this happens we shall see the final collapse of Bolshevism and the regeneration of Russia.

This regenerated Russia will be something very different in its social structure from the country I spoke to you about in the beginning of my paper. I mentioned there the old ruling class of Russia, a class of military gentry and *intelligensia* that created the old Russian culture with all its defects and qualities. Now it will be superseded by other classes. The revolution has brought with it a violent process of the liquidation of great landed property which has passed now into the hands of the small peasant farmer. The Bolshevists are here for nothing. They wanted to convert the land into communal Soviet property, practically " No Man's Land," but that never succeeded; and they did not insist particularly, as Marx's theories on the question of land nationalisation are not quite explicit. Only last week a wireless from Moscow announced officially that out of the 23,000,000 desyatine (about 100,000,000 acres) of gentry property only three millions are run on communistic lines, the rest passed into the hands of the peasants as private property. Of course, all this is nothing but a great organised robbery. But we saw the same thing during the French Revolution. And everyone of us knows that the land will not return to the original owners. They might recover part of it; they certainly should receive some material compensation. But anyhow the peasant will remain what he is now, " the great master of the Russian land," a title that formerly belonged to our Emperor. And the Russian peasant having increased his property and having learned very much in the last five years, more than probably one realises now, having acquired as I told you new commercial and industrial tastes, will ask for an ever-increasing share in the government of the country and the ruling of its destinies.

At the same time it is very certain that the importance of that part of the Russian population, which could be compared to the British lower middle classes, will also go on increasing. I think that at the present moment they have a great part of the decisions in their hands, vacillating as they do between the different fighting forces, hating Lenin and unwilling to support Denikin. From the economic point of view we might say that they are grouping themselves around the so-called co-operative organisations. I am not inclined to exaggerate the importance of this famous co-operative movement, which has been fostered by accidental causes; first a great supply of Government money, and then under the Bolsheviks the impossibility of destroying co-operation owing to its purely democratic character. By being too enthusiastic about co-operation in Russia we run the danger of injuring private individual energy, which is, as a matter of fact, of the utmost importance. But still I cannot deny the healthy foundations and the wonderful progress of this great Russian co-operative movement. As I find in the most interesting report of the Canadian Trade Commission on Serbia, given to me by Mr. C. F. Just, the membership of co-operative organisations adherent to the Centrosoyouz, or the All-Russian Central Co-operative Union, amounts to 25,000,000 persons. This Centrosoyouz serves about 500 districts, associations having 40,000 stores of their own for distribution of products among the population.

At the present time the Centrosoyouz has joint stock amounting to about 10,000,000 roubles, capital stock of about 5,000,000 roubles, over 20,000,000 roubles in movable property and real estate, particularly in its own industrial establishments, and about 300,0000,000 roubles in floating capital. The turnover amounts to 9,000,000,000 roubles.

In 1917 the commercial transactions of the Centrosoyouz reached the sum of 250,000,000 roubles, while last year, 1918, the sum amounted to 1,000,000,000 roubles. And as a curious phenomenon I should like to note that many repentant revolutionaries, too moderate for following the Bolshevists, have joined now the co-operative movement, and are to be found among its most energetic workers.

But the actual guidance of the two above-

mentioned classes, which are both yet far from being politically ripe enough, will find itself in the hands of the *bourgeoisie*, the employers, the factory owners, the leaders of great concerns. As I told you these are yet few, but they are bound to become every year stronger and more numerous. Many of the best representatives of the old nobility will almost surely adapt themselves to the new conditions by joining this class. From this point of view, as from others, the development of Russia will take the same course as the development of other countries, where the rule of the *bourgeoisie* followed the rule of the nobility.

It is beyond doubt that the joint effort of those new classes, which are now coming slowly but surely into the power of Russia, will have one and practically only one aim—the development of the productive force of the country.

And this leads me to talk about the possible future perspectives. Needless to say, they are tremendous. The first part of my paper gave some material to form a judgment on this question. Take the problem of agriculture. In 1912 there was under cultivation of the entire land area of European Russia 17·5 per cent., and throughout Russia only 5·2 per cent. This means that 95 per cent. of Russia's land area was uncultivated (40 per cent. under wood, 20 per cent. swamps and rocks), and still the cultivated territory is five times greater than the cultivated territory of Germany. I gave you above the comparison between the harvest results of Russia and some oversea countries. If we compare the average yield of Russia with European results we see that they are about three times less than in Germany or Great Britain, and more than four times less than in Denmark (the annual average wheat yield for the period of 1901 to 1910 in poods per desyatine was: Russia, 45; Germany, 130; Great Britain, 148; Denmark, 183). Those poor results are explained by an extensive culture insufficiently provided with machinery and fertilisers. Germany spends on artificial fertilisers 400 million of marks a year, Russia —ten times less on a space that is five times as great. If we would bring the harvest of Russia to the average yield of Austria or Bulgaria—*i.e.*, 80 poods the desyatine—a certain possibility—that would give a surplus of grain of 25,000,000 tons a year. Enormous spaces of agricultural Russia are, if cultivated, exploited for local needs only. Siberia has transported by rail only 1·3 per cent. of her grain production, the rest remained on the spot. The position can be entirely changed by creating in Siberia granaries and elevators for keeping and drying the grain which is generally collected during the wet autumn season. Siberia has practically not yet entered into the world market as a grain producer. And in spite of all this Russia was already one of the world's principal producers of grain. According to estimates made by experts, she produces 51 per cent. of the rye, 25 per cent. of the oats, 33 per cent. of the barley, and 22 per cent. of the wheat grown on the surface of the globe. What importance it would have in the world's supply if Russia reappeared again as furnisher of grain in quantities twice as large as those just named! And what a change in the rate of exchange in this country if she could get her supply of grain from Russia in barter for manufactured products, instead of making daily increasing payments of legal tender to the U.S.A. and Argentina!

The same wonderful possibilities are to be found in the domain of farming. The last ten years before the war, the Russian export of butter and eggs went on increasing in a geometric progression and amounted finally for each of these products to £8,000,000 or £9,000,000 yearly. And yet Russia, the classical land of cold, was extremely badly furnished from the point of view of cold storage and refrigerating cars. Whereas the U.S.A. had over 100,000 of these cars, the number in Russia amounted in 1914 to 3,414, and as every Russian wagon could bear only fifteen tons against thirty in the U.S.A. the facilities of America were sixty times those of Russia. The U.S.A. had, in 1914, 19,000 cold storage plants and Russia only 407. Needless to say, the re-organisation of Russia from this point of view would lead to a very great increase of her activity in the domain of farming. Practically every new great plant creates a new local production, as has been shown so well by the experience of the British firm of Westley Bros., who brought to life the bacon industry in Kougan and the export of eggs from Tambov and Kosloff. The increase of Siberian butter export was in full parallel with the increase of the number of refrigerating cars. The importance of Russia as producer and exporter of meat has been up to the present infinitesimal, in spite of the enormous steppes of Western Siberia and other parts of the great country. The lack of refrigerating plant was one of the main reasons. On the Russian railways meat was transported only in winter time, and in the other seasons cattle were

brought to the production centres alive, which was four times less advantageous. And as to the number of cattle, Russia had only 390 head of cattle per 1,000 inhabitants against 5,320 in Argentina and 4,600 in Australia. Shortly before the war there had been elaborated a big scheme of refrigerating installations on the ways from Siberia, Turkestan, Caucasus and Crimea to Moscow and Petrograd. The execution of this scheme, which was estimated to cost 45,000,000 roubles, should certainly be taken up one day, as it is sure to bring a very considerable quantity of butter, mutton, fruits and fish to the Russian consumption centres and to the world market.

Now a few words about timber, which, after agriculture, occupies the second place of importance in the natural resources of the Russian Empire, and the second place, after wheat, in value of exports, having increased from a total of £6,500,000 in 1905 to £16,500,000 in 1913. I want first of all to remind you that Russia accounts for nearly 50 per cent. of the grand total afforestation of the world, without including the vast areas of unexplored forests in Siberia, and that of the total exports of Russian timber, Great Britain has taken 40 per cent. in bulk and in value. It would lead me too far if I entered into consideration of the possibilities of an expansion of the Russian timber trade, given a rational exploitation of the vast forest territories of Archangel and Siberia, and the amelioration in the conditions of the water-ways. I will content myself by saying that the possible annual export of lumber from Siberia may be put at about 6,120,000,000 cubic feet; the licensed annual export specified on Government permits in districts accessible for exploitation under the present system of transportation is 1,351,000,000 cubic feet, whereas the actual amount utilised hardly reached, in 1918, 18·5 of the licensed amount, or 251,000,000 cubic feet, and only 4·1 of the possible amount: 96 per cent., 4,700,000,000 cubic feet of timber in Siberia, is left entirely unexploited.

If we turn to other industrial activities the same limitless horizons open before us. The importance of Russia as a producer of copper, oil, platinum, asbestos, is known and must not be underrated. In the domain of cotton Russia produced in 1914 1,300,000 bales, more than half of the consumption of her mills, and still Russia had only a share of 3 per cent. in the world production, and the per capita consumption of cotton in Austria-Hungary was from 40 per cent. to 45 per cent. greater than that of Russia, whereas that of France or Germany was about three times that of Russia. Cotton-growing has a great future in Turkestan, depending almost entirely upon the increase of irrigated lands. Practically only 250,000 acres have been supplied with water, whereas the land available for irrigation is estimated at 7,500,000 acres. To close this enumeration I want to point to the great possibilities of expanding the coal and mining industry in Southern Russia. The matter is a most important one, as the needs for metallurgical products for rails, agricultural machinery, roof-iron, etc., as well as for fuel in different branches of industry, will be felt in an extremely acute way. Before the war Russia produced 4,644,000 tons of pig-iron (67 per cent. of which came from Southern Russia), while the existing equipment of the blast-furnace plants would suffice to bring the smelting of pig-iron up to approximately 6,000,000 tons, which would exceed the maximum of production reached up to this time by almost 30 per cent. And if one began to construct new plants the possibility of getting raw material would not present the slightest difficulty. The iron-ore deposits for example in the Krivoi-Rog district are estimated at 100,000,000 metric tons. In the Urals one mountain alone, the Magnitnaya, has resources of over 100,000,000 tons of ore. For coal which was produced before the war in a quantity of 30,000,000 tons yearly, the prospects are just as good. Since the discovery of the Donetz coal basin only 2 per cent. of the total deposits have been utilised.

I am afraid that you might accuse me, after listening to the remarks I have just made, of entering into the domain of phantasy. I could reply to you that all my statistics are based on official censuses, verified by scientific research; but I cannot deny that I am speaking about what we call the music of the future, and I prefer to return into the realm of the sad actuality. And this actuality is so moulded that before starting any scheme in any of the directions enumerated the future Government of Russia will have to solve four extremely complicated economic problems. I do not speak about the re-establishment of a legal government in Moscow, which is the preliminary condition to any reasonable work.

I speak first of all about the question of denationalisation, which is not a simple affair at all. I cannot agree with Mr. Crozier Long, who goes so far as to declare that "the precipitate tearing down of the central Council for national economics and its ramifications would

produce even greater anarchy than Bolshevism produced out of the former capitular industry"; but I cannot deny the difficulties in returning quickly to the old individualistic order of things, in evaluating and repaying capital which has been spent by the Soviet authorities in a right or wrong way to run the industrial enterprises which they have nationalised, etc. A special interest will be certainly evoked by the position of nationalised banking. To consider all private Russian banking institutions as bankrupt is decidedly wrong. Professor Goldstein, in his new book about Russia, shows very clearly that the only harm that the Bolshevist could have inflicted upon the commercial banks was the confiscation of the ready cash, which, at the time of the *coup d'état*, was found in the vaults. These cash funds, however, were quite negligible in amount. "Thus, for instance," says Goldstein, "on May 1st, 1917, all the cash on hand in all the Russian joint-stock commercial banks amounted to hardly 183,000,000 roubles. The actual losses suffered by these banks from the Bolshevist confiscation, which occurred several months later, were even smaller, for, after their victory, the Bolsheviki continued to pay out to depositors on current accounts, in the beginning, at the rate of 650, and later at 1,000 roubles, per month. Besides, they also paid out very large sums from current accounts when these went for the payment of workers' wages, clerks' salaries, etc., in various industrial plants. Thus the cash losses of the private commercial banks were considerably offset by the payments made by the Bolsheviki upon current accounts of the private banks from the funds of the State Bank."

Then again one must not lose sight of the fact that the depreciation of the rouble reduces the liabilities of the banks to a negligible sum, whereas their assets, which consist, in large measure, of controlling blocks of stock in important industrial enterprises which own valuable mines, oil lands, and vast tracts of timber lands, are bound to increase immensely in value.

On the other side, it is impossible to minimise the importance of the heavy shock that the banks will have suffered. But their expansion and the establishment of new banks will have probably very good chances, the more as Russia had one branch office only for every 250,000 of population, as against 2,400 in Canada.

The second and third problems are still more difficult and complicated. They are the establishment of a healthy currency and the reorganisation of railways. To-day it seems that practically everybody is printing money in Russia. How much has been printed by all the different governments and armies nobody seems to know. In the report of the Canadian Trade Commission I have found the following estimate of currency outstanding, made at Omsk on March 28th by Mr. Michayloff, Minister of Finance in the Siberian Government. He stated there are now outstanding, according to figures furnished the government :—

1. Of the Romanoff and large denomination Kerensky note issues—35 milliards of roubles.

2. Of the Kerensky issues of forty and twenty-rouble notes—70 milliards.

3. Of the Imperial, Kerensky, and Bolsheviki bonds and Treasury bills—20 milliards.

4. Of the Siberian (Kolchak) Government issues and Treasury bills—1½ milliards.

A total of 126½ milliards of roubles. This is exclusive of local and municipal issues, estimated at 200 millions.

Since then the amount of paper money has considerably increased, and amounts to-day probably to about 200 milliards. I do not know if there will ever be a possibility of raising the value of the old rouble to some reasonable figure. Serious economists are, as I see, inclined to think that a new monetary unit will have to be established. It would lead me too far if I entered into any detailed discussion of this question. I should like only to point out that the question is extremely aggravated by the monetary crisis of the whole world; formerly it was an axiom that there must be a very definite correspondence between the paper money and the gold, and we were, in Russia, extremely proud of our gold fund, of 1·5 milliards of roubles—the greatest in the world. To-day nobody can tell in a definite way what the real foundation of a healthy monetary system is. I read the other day in the final report of the Cunliffe Committee, that the adoption of a currency not convertible at will into gold, or other exportable coin, is "likely in practice to lead to other issues, and so to destroy the measure of exchangeable value"; but this indication of a competent board of specialists seems to me to be vague enough. Under those conditions, when nobody practically knows what ways will be taken by the future evolution of the currency problem in Europe, it is probably premature to offer remedies specially for Russia. But one thing can be said with certainty,

Russia will not be able to solve the problem without active aid from outside.

As to the question of amelioration of transport conditions, there is no need of any further explanation of its necessity after all that I have said. This problem is certainly the most urgent, and, as it admits a partial solution in the non-Bolshevik parts of Russia, should be taken up at once. I must repeat again that the only way of utilising the resources of Russia for the world's market is to help her in the re-establishment of her rolling-stock, in the reconstruction of bridges, and in the bringing into order the lines and stations. If Russia could get in sufficient quantities of new rolling-stock, or even the tools and parts for repairing the old she could start at once with her economic activity.

And now I come to the last and most serious of the four mentioned problems. It is the question of reconstruction of the Russian national unity. If we take the question from the purely economic point of view, the legal position of the new boundary States has a somewhat secondary importance. Those States might call themselves as they like, autonomous, or even free. But close economic unity with Russia in its proper sense is a primordial necessity to any of the parts of the old Russian Empire. Central Russia cannot live without an outlet to the seas, she cannot exist without fuel from the Black Sea shore, sugar from the Ukraine, cotton from Turkestan, butter from Siberia, etc. As to the position of the Baltic border States, it is from the economic point of view quite impossible that they can lead an independent life.

A correspondent of the *Daily Chronicle* said the other day in a telegram about the position of Estonia, which he calls poetically "a child born in the thunderstorm," that apple-growing, poultry-farming, pig-keeping and dairy-farming, are branches of agriculture which are being enthusiastically developed there. But all the enthusiasm cannot change in my eyes the fact known to every Russian that Estonia is a country extremely poor in natural resources, and producing mainly potatoes. And even with the addition of some apples or some poultry I am afraid that her ground would not produce sufficient food for her own population. As a matter of fact, the greater part of the wealth of the Baltic Provinces was due to an extensive exchange of goods that passed through their port, but came from other provinces of Russia.

I am sorry that time does not allow me to deal with this question of the economic unity of Russia at greater length. I must content myself by saying that Russia was a great living economic organism, and the old Roman fable about the interdependence of the members of a body, and the body of politics, remains for ever true. You can cut off my arm, and it is possible that my wound will be healed, but my arm cannot continue to lead an independent life.

The question of economic unity is entirely dependent for its solution on the goodwill and support of the great Powers—more, possibly, than the other three questions already mentioned.

Now, I ask you, who is going to help Russia in the solution of these great problems? It is evident that the Germans cannot be kept away from Russia, their nearest neighbour, and practically their only source of supply. Sir Bernard Pares, the great supporter of Russia in this country, tells it plainly in a letter just published in *The Times*, but at the same time he points perfectly rightly to the great danger that would be connected with the policy which would surrender Russia to German monopoly, and which would give to Germany the full control of Russian raw resources and Russian man power. Germany will not fail to take her part in Russian affairs, but why should it be the leading and all-absorbing part? It depends on British public opinion to decide this question. I had yesterday the privilege of assisting at a meeting in the House of Commons, where leading authorities in British Governmental and political life expressed unanimously their conviction of the necessity of British relief for Russia, especially South Russia—of a relief not only humanitarian, but also of an organising and commercial character. I earnestly hope that the aims of those noble and generous friends of this country will be realised, and that this country, which was the foremost in the struggle for freedom and civilisation, will play the same role in the work of reconstruction in Russia.

DISCUSSION.

MR. D. T. CHADWICK (Indian Trade Commissioner) said he could not claim a close or very recent connection with Russia, as his residence there had been brief; but, short though it was, it had stimulated his interest in that great country, and no one whose interest in Russia had once been aroused could ever lose it. They were all very much indebted to Mr. Grunwald for his excellent paper. It was a good thing to be reminded of the main outstanding facts with regard to Russia, unobscured by the temporary changes

which went on from week to week. Mr. Grunwald had done well to lay stress on the inherent riches of his country. In spite of the sort of ebb and flow which was manifest throughout the history of the world, the resources of one country after another had been brought into play as they had been needed by the world in general. At the present time the agricultural products and large mineral resources of Russia were urgently needed. It was a calamity that they were now so largely unavailable. But safety and confidence were necessary for trade. Mr. Grunwald seemed to anticipate that in the future a greater activity would be shown in the economic world by a larger class than formerly; it almost seemed as if he expected individualism to succeed communism; and if that was the case it would probably lead to a big development in Russia's commerce. Such a development would be of interest to India, because the products which India exported went into general consumption in most countries.

Mr. C. F. Just said that during his residence in Russia he had only been concerned with the development of trade relations between Canada and Russia, and had therefore not acquired so wide an outlook as those who had dealt with the country from a broader point of view. Canada was mainly interested in Siberia. Mr. Grunwald had touched upon the enormous potential resources of Siberia, and it was with that country that Canada hoped to find a great opening for the exchange of her products. In its agricultural and mineral wealth Siberia was very similar to Canada, and the experience which Canadians had had in developing those resources in their own country led them to believe that they could participate in the development of Siberia with profit both to Siberia and themselves. In view of the disturbed condition of affairs in European Russia, he thought they should concentrate upon Siberia for trade purposes. Siberia had been less disturbed than any other part of the Russian Empire, and the Bolshevik movement there had only been sporadic, and had been easily suppressed. The recent invasion of the Red troops might revive it for a time, but he doubted if that invasion would have any permanent consequences, on account of the attitude of the Siberian population. That population had been formed by emigration from Russia, and the sturdier elements of the Russian people seemed to have gone there, so that the Siberians were characterised by great self-reliance and independence. They had been remote from the centralised administration of the old régime, and the paralysing arm of bureaucracy had been less felt there than in European Russia. The reorganisation of trade with Siberia should be carried out by combined rather than by individual effort. There were a number of important British interests in Siberia which could be linked together to form a chain of posts throughout the country, and could deal with the trade position both with regard to exports and imports. Owing to the great depreciation in Russian currency, it was impossible to obtain payment in cash for imports, but by collecting produce and exporting it against imported goods a system of barter could be introduced to the advantage of all concerned. The two great obstacles in the way of a renewal of trade with Siberia were the transportation and the currency questions. The transportation question had been tackled the previous spring by an Allied Technical Commission working in conjunction with the Russian railway administration, and in Siberia the state of affairs had already been materially improved; and although it might take some months before normal conditions were re-established, things were tending in that direction. The currency difficulty could be largely overcome by the system of barter he had suggested, and the position in that respect would be greatly eased by improved transportation. He was glad Mr. Grunwald had referred to the Co-operative movement in Russia. Personally, he thought it would prove the principal factor in the economic regeneration of Russia.

Mr. E. A. Brayley Hodgetts said they had all listened with the greatest pleasure to Mr. Grunwald's very able paper. The remarks he proposed to make were not in any way intended to be personal, and he hoped that Mr. Grunwald would not take them as such. In order to appreciate properly the commercial development and history of Russia it was necessary to understand that the curse of that country had been her bureaucracy. There had been eminent exceptions, but speaking generally the bureaucrats of Russia had done their best to prevent the people from developing their industrial and commercial resources. Although they had not consciously sought to prevent that development, they had been afraid of allowing the people to do it themselves, and that was why they had opposed the co-operative movement so strongly; they saw in it a threat to their own existence. Until 1861 the majority of the population of Russia were serfs, who were managed by their masters, the landowners, when they were not owned by the State. The people lived under patriarchal conditions, and there was practically no officialism at all. The Emperor was far away, and it was to the interest of the landowner to keep his serfs contented. When an official visited the neighbourhood he was driven away by bribes. In 1861 that system was upset, and the old system of co-operative working was re-stimulated in Russia, for the peasants had always tilled their ground on co-operative lines, and during the long winters when they could not work at home they would band themselves together and go to the neighbouring towns and work in the factories, pooling the wages they earned there without reference to the amount each man had received. That was the beginning of the co-operative idea. The idea of co-operation was rooted in the Russian

people. When the freed serfs tried to sell their produce they were met on their thresholds by the profiteer, the koulak, or fist, as he was graphically described. He had them in his power and was able to dictate the price at which they should sell their produce to him, and the price at which they should buy from him such articles as they required. The co-operative movement was a movement to get rid of the profiteer. The co-operative movement *per se* was a purely economic movement, although no doubt there had been politicians who had seen that it might be used to their advantage for political purposes. By organisation amongst themselves the peasants had been able to improve their selling prices, and had even erected granaries and engaged specialists to show them how their methods could be improved, and had also adopted a system of co-operative buying. Gradually the single societies combined and formed great unions which became a danger to the State because they threatened to monopolise every form of economic activity to the exclusion of private enterprise. One of the causes of the Revolution was the friction between the bureaucracy and the co-operative societies and county and municipal councils working together. The co-operative societies stood for self-help, and it was by self-help, and not by the creation of an army of officials, that Russia would be regenerated. One of Russia's difficulties was that the educated classes were not sufficiently numerous; with a large bureaucracy they nearly all became officials, and there was nobody left to run the business of the country. The old-fashioned Russian merchant was entirely uneducated, though a very decent and honest person, with a strong admixture of shrewd cunning. The Revolution had swept away that class altogether, and had substituted for the tyranny of the old bureaucracy the tyranny of the Commisars. The first thing to do was to encourage self-help among the Russian people, and the next to bring about some method of intercommunication. Although the population of Russia was estimated at 185,000,000, we had no means of communicating with them; there was no proper postal or telegraphic service, even with the South of Russia. Constantinople was administered by a British High Commissioner, who was most anxious to promote good relations with the whole of the Black Sea littoral; but in spite of that a letter took two months to get to South Russia, and was very often lost when it got there; and the idea of expecting a reply was fantastic. It was impossible to cultivate commercial relations as long as that state of affairs existed. Mr. Grunwald had said much in praise of Count Witte. Nearly twenty years ago, as their Chairman might remember, a paper was read before the Society on the Iron Industry of Russia,* in which they were told how Count Witte had created that industry in the South of Russia by promising large orders for rails, and how, when it became inconvenient for him to continue his railway policy, he had stopped those orders and had said to the manufacturers: "You have been established for five years, and now you ought to have built up a business for yourselves." Count Witte omitted to add that their only customer had just dropped them; and the result was that the iron industry of South Russia was temporarily ruined. It was always unhealthy to have a government-fostered industry, stimulated by artificial means: a healthy natural development was much better. If an artificial development was successful—and in nine cases out of ten that was not the case—it became a danger not only to itself but to the whole world, as illustrated by the example of the German Empire.

* "The South Russian Iron Industry." By Archibald P. Head, M.Inst.C.E. *Journal*, December 19th, 1902.

MR. ALEXANDER ONOU (Russian Consul-General) said that the only objection he had to find with the conclusions at which Mr. Grunwald had arrived in his very interesting paper was with reference to Germany. Mr. Grunwald had quoted a statement of Sir Bernard Pares to the effect that if the British Government did not take a certain course in favour of the anti-Bolshevik forces there was a risk of Russia becoming a German colony. He thought that was a mistaken idea. Even at the present time Russia was a formidable force. That force was minimised by the internal struggles which were taking place, but if the Bolsheviks had only to fight Poland, or even Germany, instead of Denikin, the world would see how strong they were; and if Denikin, instead of struggling against the Bolshevists, was fighting against one of the other European nations the same result would be apparent. Russia was weak only because it was torn by civil war. A year after that civil war ceased Russia would be strong again; and immediately after the first good post-war harvest Russia would be rich again. The Russian people were intelligent, and knew how to help themselves, and their country was strong; there was, in any case, no danger of Russia becoming a German colony. The real danger lay in the fact that after the war the pro-German party in Russia—it was idle to deny that such a party existed—would wish to trade with Germany rather than with Britain or France or America. It was to the advantage of the Allies to help Russia in her present difficulties. The only nation at present helping Russia was Great Britain; and it was to Great Britain's advantage to continue to help Russia with money and necessary goods, so that when the civil war was ended there would be in Russia a general feeling of gratitude towards Great Britain, and the pro-German party would be thus weakened.

THE CHAIRMAN (Sir Henry Trueman Wood) said he had great pleasure in proposing a very hearty vote of thanks to Mr. Grunwald for his interesting and valuable paper. He was sure it was the hope of all in this country that Russia might soon again take her proper place among the nations under whatever form of Government—

provided it was a civilised Government—her people chose to adopt. The work which was being done by the Russian Manufacturers' and Merchants' Association in London—which was really a sort of Chamber of Commerce—would help towards that end; and he hoped that before very long they would be able to resume trade relations with Russia. Russia had been a good customer of England's in the past, and produced great quantities of raw materials which English manufacturers were anxious to obtain. He hoped that the paper which had been read that afternoon would contribute towards that happy event, and they were all much indebted to Mr. Grunwald for delivering it.

The vote of thanks was then put and carried unanimously.

MR. GRUNWALD, replying to the discussion, said that the Consul-General (Mr. Onou) had dealt with the Russo-German situation more fully than he had been able to do in the time at his disposal; personally, he had rather avoided it as being a political question. He would be only too glad if Mr. Onou's optimistic predictions as to the rapid recovery of their country proved to be correct. With reference to Mr. Just's remarks about Siberia, when a man's house was burning down he did not pause to consider by which door he should enter to put out the flames. He would like to point out that South Russia was nearer to Western Europe than Siberia, and required the greatest attention, and it was in South Russia that the political and military anti-Bolshevist elements were chiefly concentrated. He thought that Great Britain should pay the greatest attention to South Russia, while not neglecting Siberia. He would be the last to deny the importance of the co-operative movement, and the statistical data he had given would show that he was impartial in the matter; but private initiative and enterprise had to be encouraged in Russia, and the fostering of one movement should not be allowed to hamper other movements. The activities of the municipal and county councils in running mills, making trade, and so on, were due to the abnormal conditions prevailing in Russia. He would like to see those things done in the future in Russia, as they were elsewhere, by private enterprise. As to the bureaucracy in Russia, to which one speaker had referred, in view of what had taken place in that country since the Revolution the only thing for every single man to do—no matter what class he belonged to—was to go down on his knees and say *mea culpa*—the bureaucracy not excepted. Mr. Brayley Hodgetts had mentioned Count Witte. He had had the honour of commencing his service under Count Witte. Count Witte had committed many faults—as who had not?—but it was necessary to bear in mind the difficulties under which he laboured and also the enormous work he achieved. It was all a question of what class was going to rule Russia. The bureaucracy in the past was bad because the ruling class, of which it was only an instrument, was too remote from the domain of economics, but he hoped that the new ruling class that would arise would be more in touch with the real necessities of modern life and bring about the great economic regeneration which they expected.

The meeting then terminated.

TRINIDAD LAKE ASPHALT.

The famous asphalt lake in Trinidad has always presented great difficulties in efforts to ascertain its depth through boring operations, as the constant movement of the asphalt tends to break, or render crooked, pipes or boring appliances driven into the lake at any considerable depth. Some borings, however, recently made under the direction of the chief geologist of the New Trinidad Lake Asphalt Co., which has the concession from the Trinidad Government for mining asphalt from the lake, have reached a depth of 150 ft., the lowest depth yet obtained. The previous record was 135 ft., reached in 1893. On both occasions the asphalt was found to have the same uniform character as in borings higher up and in other parts of the lake.

The record borings made in 1893 were accomplished by driving down a 2-in. pipe and washing the material out of the pipe by means of a jet with a steel bit on the bottom of it. At the depth of 135 ft. the pipe became so crooked, owing to the movement of the asphalt, that further progress was impossible.

In the borings which have recently been made, writes the United States Consul in Trinidad, a core of asphalt was taken by driving a small pipe into the pitch, and then withdrawing it with its contained core of pitch. Following this, a pipe of 2-in. diameter was driven to the lowest depth to which the core was taken, and the material, forced into it by driving, was removed by means of a water jet and bit. Another core was taken below the 2-in. pipe in the untouched pipe. The deepest of these borings was taken at the centre of the pitch lake, and the asphalt was found to be of uniform character throughout. After completion, this hole was observed to have shifted at the surface 25 ft. in six weeks; a survey showed the movement to exist as deep as 100 ft., and there was a suggestion that the direction was reversed at a depth of between 25 ft. and 50 ft. The other borings, not at the centre of the lake, shifted to a lesser extent. The movement of the asphalt seems to be similar in many respects to the ascending and descending currents in a kettle of boiling water.

The asphalt lake of Trinidad is situated at Brighton, 12 miles west of San Fernando, 27 miles south of Port-of-Spain, and about half a mile from the Gulf of Paria. The lake itself is a flat area of approximately 120 acres, forming a basin surrounded by a low hill.

The original elevation of the lake surface was 137½ ft. above sea-level, but mining operations had lowered this elevation to about 130 ft. in 1918. The asphalt is dug by hand, by labourers using a mattock which, at each stroke, lifts the asphalt out in single chunks weighing usually 60 lb. The labourers carry these large blocks upon their heads to the cars in which they are hauled away.

Crude asphalt as it occurs in the lake is of a very uniform composition, as has been determined by a large number of analyses. The composition is approximately 30 per cent. moisture, 60 per cent. asphalt in a very intimate, uniform emulsion, in which a large portion of the material is in a colloidal condition, and a small amount of mineral matter. During the process of heating or drying the moisture is removed by evaporation, but the mineral matter and asphalt remain in their same uniform proportions, which is one of the important properties peculiar to the Trinidad Lake asphalt, and not common to other mechanical mixtures of asphalt and mineral matter. In appearance asphalt, when dried, changes from a dull, black, spongy substance, to a hard, brittle, jet black, shiny product. Animals or wagons could pass across the lake if they would continue moving, but any weight allowed to remain quiet upon the surface will sink.

From the lake there are two systems of tramway. One is operated by an endless cable, which takes the cars to a terminal station, where the buckets of asphalt are transferred to an overhead cable tramway, conveyed to the loading jetty, a distance of nearly a mile, there dumped into the holds of steamers, and shipped to foreign markets as crude Trinidad Lake asphalt. The second system carries the asphalt in cars of approximately one ton capacity up an incline to the drying plant, where they dump direct into drying stills. In these the moisture is driven off by means of steam coils, and after two days' heating the asphalt is drawn off in a molten condition from the bottom of the drying stills, poured into barrels, and placed in the storage shed until ready for shipment. Then the barrels are rolled from the shed to carriers on the overhead tramway, conveyed to the loading jetty, and lowered into the hold of the steamer.

The holes dug in mining the asphalt soon fill to the same level as the rest of the lake, thus enabling digging to be repeatedly done in the same places. The lake is in constant, but slow and powerful, movement, and material left upon the surface frequently shifts its position and finally subsides. Over the surface of the lake there are a number of peculiar **V**-shaped crevices, very sharp at the bottom, with convex side slopes, apparently places where the asphalt descends from either side. To balance this descending movement, there are small raised places from 1 in. to 4 in. higher than the average flat surface, at which the ascending movement probably occurs.

In many parts of the lake, particularly near the centre, a gas containing hydrogen sulphide is given off in noticeable quantities, and any brass material left near the centre of the lake is tarnished in less than a day. The gas is similar to that obtained in the oil wells within sight of the lake. During the dry season the water which is in the pools near the centre of the lake, and which has not been diluted by rain, is slightly mineralised, indicating a possible origin below the surface. The quantity is small, and during the dry season becomes practically negligible. During the rainy season a great deal of water flows into the basin of the pitch lake, and after a succession of hard rains it is completely covered with water, which is pumped off, however, by means of electric centrifugal pumps.

At the centre of the pitch lake there is an area of soft, black, sticky, viscous asphalt, approximately 50 ft. wide.

In various portions, scattered about the surface of the lakes, are "islands," often 300 ft. long, on which trees are growing. When removed to facilitate mining operations these "islands" appear to consist principally of a thin layer of decayed vegetation and soil, the bottom of the layer being of various depths, very much creased, and seldom extending deeper than 3 ft.

Throughout the area east, north, and west of the pitch lake, and extending to the sea, which is less than a mile distant, are many small areas or patches of asphalt of variable composition, consistency, and appearance; these are the source of what is called "Trinidad Lake asphalt." Shipments of this substance have been made at various times, but the quantity shipped is very small, and it has been almost nothing since 1910.

At Guanoco, State of Sucre, Venezuela, there is another asphalt lake, known as the Bermudez Lake, from which large shipments have been made, almost entirely to the United States. This lake is of a different character, and the asphalt is quite unlike that from the Trinidad Lake.

GENERAL NOTES.

THE MINERAL RESOURCES OF THE EMPIRE.—The Mineral Resources Committee of the Imperial Institute has arranged for the issue of a series of monographs on the mineral resources of the Empire, of which one on zinc ores has already appeared. Others on manganese ores and tin ores are now published by Mr. John Murray. The monograph on manganese ores has been prepared under the direction of the Committee by A. H. Curtis, B.A., F.G.S., and that on tin ores by G. M. Davies, M.Sc., F.G.S., of the staff of the Imperial Institute. In each case the book is arranged in three chapters. The first gives a brief survey of the occurrences of the ores and of the characters and uses of the metals. The second chapter deals fully with the sources of supply within the Empire and the third describes shortly the deposits in foreign countries. The

monographs conclude with a bibliography of the principal publications on the subjects dealt with. The monographs are published at 3*s*. 6*d*. net. Owing to its extensive employment in the manufacture of iron and steel, manganese was in great demand during the war. Unfortunately there was a serious shortage of manganese ores, as supplies from the Caucasus, the chief producer, were cut off, and shipping difficulties restricted the amount available from India, which ranked second only to Russia as a producer of manganese ores. At the present time the output from India is increasing and Brazil has enormously enlarged its production, but in view of the disturbed conditions still prevailing in Russia, there is likely to be a continued shortage of the ore there for some time to come, particularly of the higher grades now required by metallurgists and in chemical industries. Several additional sources are indicated as possible contributors to the world's supply in the future. The Empire is favourably situated as regards supplies of tin ore, and at the present time between 50 and 60 per cent. of the world's output is obtained from British countries. Moreover it holds a controlling influence in the industry of tin smelting and refining. The Federated Malay States is the most important tin-producing area in the world and most of its output, together with ore from Siam, the Dutch East Indies, South Africa, and other countries, is smelted in the Straits Settlements. Bolivia and the Dutch East Indies are the chief foreign producers of tin ore. Owing to the war the German tin-smelting industry has practically ceased, and another result of the war has been the establishment of a tin-smelting industry in the United States, which country consumes 40 per cent. or more of the world's output of tin. Among British sources of supply of tin in the future Nigeria is specially referred to.

THE CHADWICK TRUST AND NAVAL AND MILITARY SANITATION.—The Chadwick Trustees have resolved, under the powers conferred upon them by the scheme which they administer, to award, in the year 1920, a Chadwick Gold Medal and a prize of £100 to the naval and military medical officer respectively in the British service who during the past five years of war shall be deemed to have distinguished himself the most in promoting the health of the men in the Navy and Army. The nomination to the Trustees for such presentation will, as provided by the Trust, be made by the Directors-General of the Naval and Military Medical Services respectively.

NEWFOUNDLAND IRON MINES.—The enormous demand for iron during the war gave a new impetus to the mining industry of Newfoundland. Some of the mines at Bill Island are among the most remarkable in the world, says *United Empire*. There are two areas, both rich in iron ore, one of which has an annual output of 700,000 tons, and is credited with a supply which should be sufficient to last at this rate for nearly 850 years; while the other, with an annual output of 600,000 tons, is believed to contain enough ore to last for about 3,300 years. Newfoundland may therefore be regarded as having an almost inexhaustible supply of iron. The mines are conveniently situated near the coast, where ships of 7,000 tons can be loaded in six or seven hours. The iron is then sent to Nova Scotia for smelting and refining processes.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

JANUARY 21.—ALFRED H. POWELL, "Ancient Cottages and Modern Requirements." The Right Hon. EARL FERRERS will preside.

JANUARY 28.—SIR CECIL HERTSLET, late H.B.M. Consul-General for Belgium, "The Ruin and Restoration of Belgium." EMILE CAMMAERTS will preside.

FEBRUARY 4.—ALFRED E. HAYES, General Secretary, English Language Union, "The English Language and International Trade."

FEBRUARY 11.—LIEUT.-COMMANDER NORMAN WILKINSON, R.N.V.R., O.B.E., R.O.I., R.I., "Naval Camouflage."

FEBRUARY 18.—SIDNEY PRESTON, C.I.E., "English Canals and Inland Waterways."

FEBRUARY 25.—JAMES CURRIE, C.M.G., Ministry of Labour (Training Department), late Principal, Gordon Memorial College, Khartoum, "Industrial Training."

MARCH 3.—WILLIAM JAMES GARNETT, First Secretary, H.B.M. Diplomatic Service, "Mongolia from the Commercial Point of View."

MARCH 10.—H. M. THORNTON, "Gas in relation to Industry and Housing."

Dates to be hereafter announced :—

AIR-COMMODORE EDWARD MAITLAND, C.M.G., D.S.O., "The Commercial Future of Airships."

BRIGADIER-GENERAL SIR HENRY P. MAYBURY, K.C.M.G., C.B., M.Inst.C.E., "Road Transport."

CHARLES H. SHERRILL, "Stained Glass."

LADY INGLEFIELD, President, Buckinghamshire Lace Association (North Bucks and Bedfordshire), "The Hand-made Lace Industry."

GRAILY HEWITT, "Rolls of Honour."

CHARLES CROWTHER, "The Arts and Crafts of Japan" (with examples from the author's private collection).

WILLIAM CRAMP, D.Sc., M.I.E.E., "Pneumatic Conveying Plants, with special reference to the Transport of Grain."

L. GASTER, "Industrial Lighting in its relation to Efficiency."

BRIGADIER-GENERAL LORD MONTAGU OF BEAULIEU, C.S.I., "Roads and Transport in India."

SIR GEORGE CUNNINGHAM BUCHANAN, K.C.I.E., M.Inst.C.E., "The Ports of India: their Administration and Development."

SIR JOHN HUBERT MARSHALL, C.I.E., M.A., Litt.D., F.S.A., Director-General of Archæology in India, "Recent Archæological Discoveries in India."

SIR VALENTINE CHIROL, "The Enduring Power of Hinduism." (Sir George Birdwood Memorial Lecture.)

SIR FRANCIS WATTS, K.C.M.G., D.Sc., Imperial Commissioner of Agriculture for the West Indies, "Tropical Departments of Agriculture, with special reference to the West Indies." LIEUT.-COLONEL SIR DAVID PRAIN, C.M.G., C.I.E., LL.D., F.R.S., Director of the Royal Botanic Gardens, Kew, will preside.

INDIAN SECTION.

Thursday afternoons, at 4.30 p.m:—

February 19, March 18, April 15, May 20.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 p.m.:—

February 3, March 2, May 4.

CANTOR LECTURES.

Monday evenings, at 8 p.m.:—

CAPTAIN H. HAMSHAW THOMAS, M.B.E., M.A., F.G.S., Fellow of Downing College, Cambridge, and formerly of the Royal Air Force, "Aircraft Photography in War and Peace." Three Lectures.

January 19, 26, February 2.

CHARLES FREDERICK CROSS, B.Sc., F.R.S., F.C.S., "Recent Research in Cellulose Industry." Three Lectures.

February 16, 23, March 1.

WALTER ROSENHAIN, B.A., D.Sc., F.R.S., Superintendent, Department of Metallurgy and Metallurgical Chemistry, National Physical Laboratory, "Aluminium and its Alloys." Three Lectures.

April 12, 19, 26.

ARTHUR THOMAS BOLTON, F.R.I.B.A., F.S.A., Curator, Soane Museum, "The Decoration and Architecture of Robert Adam and Sir John Soane, 1758-1837." Three Lectures.

May 3, 10, 17.

JUVENILE LECTURES.

Wednesday afternoons, at 3 p.m.:—

LOUGHNAN PENDRED, M.I.Mech.E., Editor of *The Engineer*, "Railways and Engines."

January 7, 14.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JANUARY 5...Chemical Industry, Society of (London Section), at the Chemical Society, Burlington House, W., 8 p.m.

Geographical Society, 135, New Bond-street, W., 8.30 p.m. Professor J. W. Gregory, "The African Rift Valleys."

Colonial Institute, Central Hall, Westminster, S.W., 3 p.m. (Juvenile Lecture.) Mr. W. H. Garrison, "Volcanoes and the Fire Belt."

TUESDAY, JANUARY 6...Royal Institution, Albemarle-street, W., 3 p.m. (Juvenile Lecture.) Professor W. H. Bragg, "The World of Sound. Lecture IV.—Sounds of the Town."

Colonial Institute, Central Hall, Westminster, S.W., 3 p.m. (Juvenile Lecture.) Mrs. J. W. Henshaw, "A Story of the Pacific Coast."

Photographic Society, 35, Russell-square, W.C., 7 p.m. Dr. G. H. Rodman, "The X-Rays approached from a Popular Standpoint."

WEDNESDAY, JANUARY 7.—ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 3 p.m. (Juvenile Lecture.) Mr. L. Pendred, "Railways and Engines." (Lecture I.)

Automobile Engineers, Institution of, at the Institution of Mechanical Engineers, Storey's-gate, S.W., 8 p.m. Mr. D. J. Smith, "Producer Gas for Motor Vehicles."

Geological Society, Burlington House, W., 5.30 p.m. 1. Mr. S. S. Buckman, "Jurassic Chronology: I. Lias.—Supplement I. West England Strata." 2. Mr. F. J. North, "On *Syringothyris* Winchell and certain Carboniferous Brachiopoda referred to *Spiriferina*."

Sanitary Engineers, Institution of, Caxton Hall, Westminster, S.W., 7.30 p.m. Presidential Address.

THURSDAY, JANUARY 8...Aeronautical Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 3 p.m. (Juvenile Lecture.) Major H. E. Wimperis, "How Airmen find their Way."

Royal Institution, Albemarle-street, W., 3 p.m. (Juvenile Lecture.) Professor W. H. Bragg, "The World of Sound. Lecture V.—Sounds of the Sea."

Electrical Engineers, Institution of, at the Institution of Civil Engineers, Great George-street, S.W., 6 p.m. Mr. J. Shepherd, "Failures of Turbo-Generators and Suggestions for Improvements."

Historical Society, 22, Russell-square, W.C., 5 p.m. Miss M. Wretts-Smith, "The English in Russia in the 16th Century."

FRIDAY, JANUARY 9...London Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5 p.m. Mr. R. Unwin, "A Few Thoughts on the Development of London."

Malacological Society, at the Linnean Society, Burlington House, W., 6 p.m. 1. Dr. S. Stillman Berry, "On a new species of *Mitra* from California." 2. Dr. A. E. Boycott, "On local variation in size of *Clausilia bidentata* and *Ena obscura*." 3. Mr. H. C. Fulton, "Molluscan Notes, No. IV."

Astronomical Society, Burlington House, W., 5 p.m.

Philological Society, University College, W.C., 8 p.m. Dr. W. Perrett, "The Perception of Sound."

Marine Engineers, Institute of, The Minories, Tower-hill, E., 6.30 p.m. Mr. J. H. Williams, "Oil from Well to Consumer."

Auctioneers and Estate Agents' Institute, 34, Russell-square, W.C., 7.45 p.m. Mr. F. W. Hunt, "Some Aspects of the Housing Problem."

SATURDAY, JANUARY 10...Royal Institution, Albemarle-street, W., 3 p.m. (Juvenile Lecture.) Professor W. H. Bragg, "The World of Sound. Lecture VI.—Sound in War.

Journal of the Royal Society of Arts.

No. 3,503. VOL. LXVIII.

FRIDAY, JANUARY 9, 1920.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

WEDNESDAY, JANUARY 14th, at 3 p.m. (Juvenile Lecture.) Mr. LOUGHNAN PENDRED, M.I.Mech.E., Editor of *The Engineer*, "Railways and Engines." (Lecture II.)

INDIAN SECTION.

Friday afternoon, January 2nd, 1920; SIR HARVEY ADAMSON, K.C.S.I., M.A., LL.D., Lieutenant-Governor of Burma, 1910-15, in the chair. A paper on "Burmese Village Industries: their Present State and Possible Development," was read by Mr. A. P. MORRIS, B.Sc., A.M.Inst.C.E., Provincial Art Officer, Burma.

The paper and discussion will be published in a subsequent number of the *Journal.*

JUVENILE LECTURE.

On Wednesday afternoon, January 7th, SIR HENRY TRUEMAN WOOD, Chairman of the Council, in the chair, Mr. LOUGHNAN PENDRED, M.I.Mech.E., Editor of *The Engineer*, delivered the first of his course of Juvenile Lectures on "Railways and Engines."

The lecture opened with a brief reference to the fact that railways are barely one hundred years old, that the earliest railways were run in connection with collieries, and that the first "real" railway, the Stockton and Darlington, was not opened till 1825—only ninety-five years ago. Many of the earliest railways were made with wooden rails and the wagons were drawn by horses or pulled by ropes. The use of the Dandy Cart, in which the horse rode down hill, was then described, and illustrations of a dandy cart were shown on the screen. The audience was then introduced to Stephenson and Trevithick, and after a few words about them the action of steam in a cylinder was explained by means of a mechanical lantern-slide.

The difficult question of adhesion was then discussed, a simple explanation being drawn from the varying adhesion of a donkey pulling a governess cart. Because the early engineers did not know that a smooth wheel had sufficient friction with a smooth rail they used various devices to get enough pull. Blenkinsop's 1813 rack locomotive was illustrated, and its modern descendant, a mountain rack-railway locomotive, was shown.

A model of Murdock's road locomotive was then explained, and a model of Brunton's curious engine that was propelled by a pair of legs was shown in action.

As early as 1803 Trevithick had nearly found the solution, and his engine of that date was illustrated; but Hedley's "Puffing Billy" marked the real adoption of smooth wheels on smooth rails.

The increase of adhesion by coupling wheels was then touched upon, and the progress of locomotives was shown by pictures of Locomotive No. 1 of 1825, and the Royal George of 1827.

These engines brought the history to a very important period. The railway between Manchester and Liverpool was drawing towards completion, but how the trains were to be hauled had not been settled. The directors therefore decided to hold trials at Rainhill, near Liverpool, for a prize of £500. The engines entered for the trial (1829) were then illustrated and described, the slides including a drawing of Brandreth's cyclopede which was driven by a horse walking on a moving platform, which formed the bottom of the "locomotive."

The lecture concluded with a few illustrations of funny funnels and a slide showing an old Bury engine beside a big modern engine, and it was pointed out that the height to the top of the chimney from the rail was practically the same in both engines.

In the second lecture some account will be

given of coaches and wagons and modern locomotives. Signalling will be explained, and apparatus and models will be shown in action, and the lecture will conclude with instructions how to drive a locomotive.

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

A meeting of the Indian Section was held on Thursday, December 18th, 1919; SIR WILLIAM DUKE, G.C.I.E., K.C.S.I., Chairman of the Indian Section, in the chair.

THE SECRETARY of the Section announced that Lord Meston, who was to have taken the chair, had been detained at the House of Lords by the third reading of the Government of India Bill, and that Sir William Duke, Chairman of the Indian Section, had consented at short notice to preside. A letter had been received from Lord Meston containing an important suggestion as to the future of Indian education, which he proposed to read before the discussion commenced. Sir Michael Sadler, Chairman of the Calcutta University Commission, had also written regretting his inability to attend. He wrote: "I am exceedingly sorry that a University meeting at Leeds prevents me from coming to hear the paper by Mr. Hartog. Great Britain and India are both under great obligations to him for his educational writings and insight. His influence upon the teaching of English has been a boon to both countries, and will grow. Every member of the Calcutta University Commission took an active part in the preparation of our report, but they would all join me in expressing our gratitude to Mr. Hartog for his valuable services in that direction." He was sure the audience would wish him to offer their sincere congratulations to Sir William Duke on his first public appearance since his appointment as Permanent Under-Secretary of State for India.

THE CHAIRMAN (Sir William Duke), in introducing Mr. Hartog, said that the condition of education in India had long been a source of grave anxiety. The large middle-class element was avid of education, and received it in enormous numbers, but the soundness of the teaching, both as a means of development in spiritual matters and as a method of approaching everyday problems, was open to considerable doubt. On the other hand, a vast mass of the population was scarcely touched by education so far as reading and writing were concerned; they were illiterate. With regard to university education, an enormous rush for degrees was accompanied by widespread dissatisfaction with those degrees as denoting a particular stage in knowledge and mental development. To deal with one of the most outstanding of those difficulties, the Secretary of State some years ago sent out the strongest Commission he could get together to inquire into and report on the difficulties which faced the University of Calcutta, and to suggest any improvements that could be made. Sir Michael Sadler was Chairman of that Commission, and Mr. Hartog one of the members. The labours of the Commissioners had extended over eighteen months, and they had prepared a most exhaustive report, which had recently been published. Mr. Hartog was, therefore, able to speak with the fullest authority, owing to his close and recent study of the subject on the spot.

The paper read was—

SOME PROBLEMS OF INDIAN EDUCATION.

By P. J. HARTOG, C.I.E., M.A.

1. A charming French lady whom I once knew said she disliked going to Chamonix because she felt so small by the side of Mont Blanc. I think we may most of us feel at first the same kind of awe and hesitation in approaching the great problems of India, all of them on a scale to which we are little accustomed in our home affairs. And yet, for reasons of a fundamental kind, the problems of India, complex and difficult as they are, have not proved unmanageable in the past. I do not believe that they will be unmanageable in the future. In spite of the fierce dislocations of history, in spite of troubles that have saddened us all, India, with its 315,000,000 of people, leads, on the whole, a peaceful, ordered, and civilised life. Yet India is moving—slowly, but, nevertheless—like the Ganges when it begins to change its course. What is the origin of this change? we may ask. How, if at all, shall we control it? To both questions many would give the same answer—Education; some, Indians and British alike, shaking their heads, and blaming the English for the introduction of disturbing Western ideas; others, Indians and British alike, rejoicing at the liberation of Indian thought from a tyrannous tradition. I have put these extreme views without sharing either. I want, if I can, to try to place the question in a truer perspective.

2. I might well hesitate to attempt such a task if I had to rely on myself alone. But I had the good fortune, for nearly eighteen months, to be working as a member of the Calcutta University Commission under the wise guidance of Sir Michael Sadler, and with very able colleagues, both Indian and European; to travel some 10,000 or 12,000 miles in India itself; to visit all the greater provinces of British India

and several of the native states; to inspect dozens of colleges and schools; to interview hundreds of witnesses; to read a great mass of carefully classified evidence dealing with the more important questions of Indian secondary and higher education. The Commission have expressed their views in a five-volume Report, which I find the Indian press generally calls "monumental," not always with any desire to flatter its authors. There are monuments of different kinds. But I believe that if the structure that we have built is monumental in size it has been made exceptionally easy of access by an ordered plan and subdivisions and summaries. A distinguished friend of mine, after reading the first volume, decided to take the whole five on a journey round the world; and I hope that no one who wishes to become acquainted with our analysis of existing conditions (based on what I believe to be a really thorough investigation), or with our recommendations, will be deterred by the fact that we run to five octavo volumes of a handy size and in large print.

3. Our reference limited us to secondary and post-secondary education in Bengal, which, with its population of 45,000,000 was sufficient to satisfy the ambitions of any Commission. But many of the problems that we attacked were by their nature All-India problems, for although there are differences between the educational systems and conditions of the various provinces, the resemblances are far greater than the differences; and if I deal largely with the problems of Bengal, with which I am best acquainted, I shall not hesitate to touch on their bearings on India as a whole.

4. At the very outset I want, if I may, to distinguish education from literacy; we shall come to the figures of literacy in a moment. But it is essential to remember that India, with its hundreds of millions of people of varied races and religions, is, as a whole, "educated" up to a point. Its populations are under the intellectual sway of complex traditions—literary and religious—developed by past generations of religious teachers, poets, and thinkers and scholars; its agriculture, which is the main material support of the country, is, if not "scientific" in the modern sense, at any rate, by the witness of those who know it best, a fine art; and it has other complex native industries. India forms a great society, or, rather, complex of societies. To regard as "educated" only those who can read and write is to ignore fundamental facts. Literacy, in the East, as in the West, may mean the reverse of education. If I hereafter use the words "education" and "educated" in their more conventional sense, you will not misunderstand me.

5. We now come to the figures of literacy and of education, primary, secondary, and higher; they are striking enough. I take them from Mr. H. Sharp's admirable Quinquennial Review of the Progress of Education in India, 1912–1917, which is itself based on census and provincial returns. Of the total population, only 5·9 per cent. are literate in the sense of being able to write a letter in any single language to a friend and to read his reply. Of the male population of India, only 10·6 per cent. are literate; only 5·31 per cent. are under instruction of any sort. Of the female population, only 1 per cent. are literate, and only 1·03 per cent. under instruction. Roughly speaking, you may say that for the great masses of population the culture of India is only oral and manual, not written.

6. Corresponding to this is the small percentage of the population enrolled in elementary schools, relatively to the figures for other countries. I quote these figures from Mr Sharp:—

	Percentage of the population enrolled in Elementary Schools.
United States	19·87
England and Wales	16·52
German Empire	16·30
France	13·90
Japan	13·07
Ceylon	8·94
Roumania	8·21
Russia	3·77
Brazil	2·61
India	2·38

The analogy of India to pre-war Russia in this respect is worth consideration.

7. When we come to secondary education, the figures are very different:—

	Percentage of the population enrolled in Secondary Schools.
United States of America	1·502
German Empire	0·988
England and Wales	0·62
India	0·486
Japan	0·354
France	0·32

The figures reveal themselves as still more significant when we find that they mean that of the *male* population of India nearly ·869 per cent. (or about 9 per 1,000) are enrolled in secondary schools, the percentage of the female

population so enrolled being only one-tenth of that number, or less than 1 per 1,000. It is true, on the other hand, that these figures include the pupils of secondary schools who are enrolled in their primary classes, and amount to nearly half the whole number. Even when these allowances are made, the contrast between the figures for primary and for secondary education is very great. You have in India an illiterate peasantry and industrial population, literate middle classes.

8. We now come to university education. The figures are comparable to those for secondary education. The following approximate figures are given by Mr. Sharp for 1914–15; they are undoubtedly liable to correction, but are sufficient to indicate the facts :—

	Percentage of population enrolled in Universities.
United States	0·218
France	0·106
Italy	0·063
Netherlands	0·066
England and Wales	0·054
India	0·024

Of the Indian *male* population the percentage receiving university education is 0·048, or, say, 5 in 10,000, not far short of the British figure for the population as a whole. If we take Bengal we find that in the University of Calcutta, which has some twenty-five of its colleges in Calcutta itself, and rather more than this number scattered through the province, there were in 1917–18 just under 26,000 students, as against the 26,700 "full-time" students in all the British universities together, in the year before the war.* The full-time students in the British universities included many who were not preparing for degrees. In Bengal all students are preparing for degrees.

9. The epithet commonly applied to Indian education is "top-heavy," and some have proposed to bring it to a stable condition by diminishing the apex of the pyramid. Our Commission believed it to be a sounder policy to extend the base. Policy, as Lord Cromer pointed out, invariably means finance, and the financial aspect of the problem is not easy. Can India—"a poor country"—afford proper education? We ask, rather: Can India, being a poor country (if it is a poor country), afford not to have it? Does not education—in the true sense, as distinguished from literacy—conmote a greater control of natural resources, which will compel from Nature a greater yield to support her population, as well as a richer moral, artistic, and intellectual life? I cannot here go into details of Indian finance, and should hesitate to do so in the presence of some whom I see here to-day; but I have been authoritatively assured that Bengal can raise much more than she now does for this, the most productive form of expenditure. The late Major J. C. Jack, whose death in the war was so great a loss to Bengal, declared, in his book on "The Economic Life of a Bengal District," that local taxation in the Presidency amounts to only about ½ per cent. of the total income of the population, and contrasted the taxation for local purposes in Bengal with that in Italy, a poor European country, which is many times as great.

It will be for the local Governments under the new *régime* to show whether the enthusiasm for education professed by so many is a real enthusiasm, willing to make sacrifices. The London ratepayer cheerfully pays an amount equal to about 10 per cent. of his rent for educational purposes; and in a vast number of cases he pays this for the education of other people's children, as he sends his own to schools not assisted by the rates. I confess that I have been disappointed to find among some Indian friends an enthusiasm for education singularly unwilling to face the clear fact that to become effective it must translate itself into a readiness to be taxed for the purpose — that it must bear the test of genuineness to which all Western nations have submitted.

10. I have said that expenditure on education would be productive expenditure. But the serious question arises as to how far it is productive in the best sense at present, and what changes are needed to make it more productive. That was the problem which our Commission had to consider. Let us briefly sketch the Indian system as it exists to-day. In the broad outlines of its organisation it does not differ very largely from European systems. It includes primary schools, secondary schools, and universities with colleges, and parallel with these a series of institutions for technical education—primary, secondary and higher. All educational institutions are officially divided into "public institutions" and "private institutions," according as they provide or do not provide a course of study recognised by Government or a university; and the public institutions may be either "publicly managed" *i.e.* directly managed by Government or by a local board or municipality, or privately

* See *Nature* for August 15th, 1918, p. 474.

managed. The privately managed institutions may again be "aided" by grants from public funds or "unaided."

11. Of the primary schools, only a few are managed by Government (1,353), a larger number are managed by local bodies (39,172), and many more are private schools (101,678, of which 85,353 are aided and 16,325 are unaided). The great majority of the primary schools are vernacular; out of 5,818,730 pupils of both sexes in primary schools, only 92,000 learn English.

12. When we come to secondary schools the question whether they teach or do not teach English (a matter on which I shall have more to say later) is an important feature in their nomenclature; they are described as "anglo-vernacular" or "vernacular." But I pass on to their general structure.

Many secondary schools contain primary classes. All "complete" secondary schools are divided, for the sake of convenience, into a "middle stage," generally of four years (but in some provinces of two or three), and a "high" stage, also varying from two to four years in different provinces. The characteristic of the "high stage" is that it prepares for a matriculation or school-leaving examination; and the highest classes in the high stage are conducted, or are supposed to be conducted, entirely through the medium of English (except in Burma, where there are a few vernacular high schools). The "complete" secondary school, with a curriculum of ten years, is supposed to take a boy up to the minimum age of matriculation, which is sixteen in the University of Calcutta and most other Indian universities. As a matter of fact, the average age of matriculation candidates presenting themselves from secondary schools in Bengal was eighteen years four months in 1918, and it is by no means uncommon to see young men of nineteen, twenty, and even twenty-one, in the high schools, a state of things which should be changed, though it can only be changed gradually.

There were in British India, in the quinquennium 1912-17, 7,693 secondary schools with a population of 1,186,335, of which 2,756, or over one-third, were in Bengal, as against 449 in Madras, 465 in Bombay, 761 in the United Provinces, and 1,400 in Burma.

13. Following on the high school comes the university course of four years for a bachelor's degree in Arts, Science, or Engineering, divided by the intermediate examination into two periods of two years. This leads on to another two years' course for the M.A. or the M.Sc., and a three years' course for the over-popular B.L. degree, which is a post-graduate degree, and is often taken concurrently with the M.A. degree. With a few exceptions university classes are conducted entirely in English.

14. There were in the quinquennium 1912-1917 five universities in India (Calcutta, Bombay, Madras, Punjab, Allahabad), to which have been recently added a new university at Patna, the new Hindu University at Benares, the new university in the native State of Mysore, and the Osmania University in the native state of Hyderabad. Others are in contemplation, notably at Dacca, Rangoon, Aligarh, Lucknow, Agra, Nagpur, and in Baroda.

During the quinquennium the five universities had 184 colleges, of which 28 were in the Native States and 57 (or not far short of a third) were attached to the University of Calcutta.* University teaching has been mainly given, up to the present, in colleges, though there are notable exceptions—especially in Calcutta and at Allahabad, in both of which universities important teaching is given directly under the university authority.†

One remarkable feature in university statistics is the high proportion of students pursuing purely literary courses—in the University of Calcutta over 22,000 out of 26,000.

15. Many Indian writers regard the development of the industrial and technical schools and colleges as the most urgent need of India.‡ But to deal even briefly with these special schools, or to do more than mention the special problems of women's education, and of the education of Musulmans and of Europeans, all full of interest and difficulty, would carry me beyond the limits of this paper.

16. Having taken this general survey of the external structure of the educational system, I wish to draw attention to five factors which affect that structure throughout, and give rise to important differences between education as we know it in Great Britain and education

* This number was slightly reduced by the creation of the University of Patna. The number of colleges in Bengal still exceeds fifty.

† The colleges are divided into "arts colleges" (in which the ordinary curriculum in science as well as in arts, leading up to a B.A. or B.Sc. degree, is given), law colleges, medical colleges, engineering colleges, and agricultural colleges.

‡ The subject of higher technical education in Bengal is discussed in the report of the Calcutta University Commission. The subject of Indian technical education in relation to the development of industries is dealt with in the report of Sir Thomas Holland's Indian Industrial Commission (1916-1918); and reference should also be made to Mr Sharp's Quinquennial Review, quoted above, especially to paragraph 13 and Chapters XI. and XII.

in India: (1) caste; (2) the seclusion of women; (3) the pay and social position of the teachers; (4) the medium of instruction; and (5) the influence of examinations.

17. Caste, which I have mentioned first as contributing the most striking of factors unfamiliar to the West, seemed to me to have surprisingly little influence in Bengal, except in one direction. Students of all castes mix freely on the benches of schools and colleges, though they do not eat together.* I am told that in some cases it is difficult for the lower castes to gain admission to school or college, but of this I saw no direct evidence. But on technical instruction, caste has an immediate influence. It is the tradition of the higher castes to despise manual labour, and though the prejudice is going, it will for many years deprive the schools of engineering, technology, and agriculture, of some who might have been their most gifted students.

18. It is perhaps hardly accurate to call the *purdah* system a factor in Indian education. On the contrary, it means, speaking broadly, that the vast majority of Indian women and girls, above the age of childhood, are excluded entirely from the educational system. In the universities, such women as are willing to attend have long been admitted to all privileges on equal terms with men.† Women students are still insignificant in numbers; but possibly the influence of women graduates may, combined with political changes, inspire *purdah* women with a desire to receive an education comparable with that of their men-folk.

19. I come to the pay and social position of teachers. The average monthly pay of the primary teacher is Rs. 9·2 (even at the present high rate of exchange under £12 a year)—often less —a pittance that would hardly satisfy a labourer. Of course, in comparing salaries with European salaries, we must bear in mind that, owing partly to climate, partly to custom, most Indians live a far simpler life than Europeans; their needs are less. Again, in many primary schools, *pathsalas* for the Hindus and *maktabs* for the Musulmans, the teaching is almost solely religious, confined to the teaching of religious texts, and given by a holy man who lives mainly on alms, thus conforming more closely to the old Indian ideal of the teacher—an ideal, I fear, that is bound to disappear largely with the increased claims of secular education.

In the secondary schools there is a far greater range of salaries; they appear to go as low as Rs. 4–5 a month, and up to Rs.400 (£520 a year at the present rate). From Rs. 25 to Rs. 50 a month is a common commencing salary. In Government and some other schools the posts are pensionable.

The average salaries of teachers (excluding principals) in the Bengal "arts colleges" in 1917 (I have not the figures for British India) were Rs. 256 a month in the Government arts colleges, rather less than half that for the private colleges. In the Government colleges, at any rate, and especially in the Presidency and Dacca colleges, the average pay would compare not unfavourably with the pre-war average of a modern English, French, or German university. In the private colleges, and especially in the case of teachers of Sanskrit, there is a marked difference, and many of the salaries are painfully inadequate. But there is, perhaps, no such general discrepancy between the Indian and British rates of payment to university teachers as exists in the case of primary and secondary teachers. Life in Calcutta is of course dear; but outside Calcutta the Indian university teacher in Bengal before the war was probably as well off as an English university teacher—in many cases better off. We cannot compare present Indian conditions with those in England, which are now being reconsidered, and which will have to be considerably modified if university teachers in this country are not to suffer serious depression in the social scale.

20. I now come to the vexed question of the medium of instruction—a question of profound importance, on which there prevails, not only remarkable misconception, but a surprising divergence of opinion, a divergence which cuts across every division of race and religion, of political views, and of occupation.*

In order to gain a clear idea of the situation in Bengal, which is in many ways, though not entirely, typical of India as a whole, we must go back rather more than a century. At that time the choice of medium of instruction for secondary and higher teaching did not lie between English and the vernacular; the vernacular was

* I was told in a chemical laboratory in Allahabad (United Provinces) that twenty years ago high-caste students would not have used water distilled by a "sweeper," but that this is no longer the case.

† Mrs. Scharlieb received her early medical training in Madras at a time when it would have been difficult or impossible for a woman to obtain medical training in this country.

* The subject is dealt with more fully in Chapters XVI. and XLI. of the report of the Calcutta University Commission.

regarded by all alike as unfitted to convey such instruction, just as the European vernaculars were so regarded in the Middle Ages. The choice lay between the classical languages of India—Sanskrit for the Hindus, Arabic for the Musulmans—on the one hand, and English on the other. The first educational efforts of the East India Company were devoted to teaching in the classical languages. The Calcutta Madrassah was opened by Warren Hastings in 1781; the Sanskrit College, under Lord Amherst's administration, in 1824. It was by voluntary effort that teaching on Western lines, through the medium of English—still somewhat mis-named in India as "English education"—was started in Bengal. That voluntary effort was of two kinds—missionary effort (which has played, and still plays, so large a part in purely secular Indian education), and the effort of two remarkable men, an enlightened and cultured Brahmin, Raja Ram Mohan Roy, and David Hare, the Calcutta watchmaker, to whose tomb Hindus make an annual pilgrimage on the anniversary of his death. These two men together founded the Hindu College, or Vidyalaya, which was opened in 1817 as the first college for English education, and established mainly by the generosity of Hindus. The taste for English in Bengal became widely disseminated, and it was reported in 1831 that independent schools, conducted by young men trained in the Vidyalaya, were springing up in every direction. It is often asserted with misplaced vehemence that English has been imposed on Bengal; it is not so. English sprang up in Bengal by the sheer desire of the Hindus to learn it, though no doubt that desire was stimulated by the wish to occupy places as clerks in Company employment and business firms. How little compulsion there was in the matter is proved by the fact that the Musulmans, who form the majority (over 52 per cent.) of the existing Presidency of Bengal, for long years stood absolutely aloof from Western education for reasons into which I cannot here enter; and they still form only 20·5 per cent. of the population of the high schools, only 8·8 per cent. of the population in the arts colleges of the university, and only 6·8 per cent. at the professional colleges. The Musulmans are now making great efforts to recover the lost ground.

21. The policy of the British Government was changed by Macaulay's famous Minute of 1835, and the action taken by Lord William Bentinck's Government on his recommendation. By that action the Government diverted to "English education" the funds previously devoted to the encouragement of the learned Eastern tongues. Macaulay's Minute has often been represented as sacrificing the vernaculars to English. As Lord Chelmsford recently pointed out in an address at Simla, this was not the case. Macaulay and the Public Instruction Committee, of which he was chairman, were "deeply sensible of the importance of encouraging the cultivation of the vernacular languages"; and, indeed (I quote from one of their reports), they "conceived the formation of a vernacular literature to be the ultimate aim to which all their efforts must be directed." If we examine the great education Despatch from the Directors of the East India Company of 1854, the Report of the Education Commission of 1882, the Report of the Universities Commission of 1902 instituted by Lord Curzon, and the Government of India's Resolutions of 1904 and 1913, we find that during the whole period since Macaulay's Minute "the policy of Government has been unswerving in its double aim of conveying Western education in its higher forms through the medium of English to the Indian peoples, and of encouraging the development of the vernaculars so as to fit them for every use." *

How far has it succeeded in this aim? Ought there now to be a change of policy? Have the vernaculars now been sufficiently developed to be used as the medium? If not, at what stage ought English to be first used as the medium? These questions have been, and are being, discussed, with passion, in India; and the evidence received in response to the questions of the Commission on this point exceeded in volume, and perhaps in ability, those dealing with any other point. I shall not repeat here the analysis of that evidence. I will only say that while some Indians of more or less advanced political views regard the use of a medium other than the vernacular as "most unnatural, unscientific, and unnecessary, and nowhere followed in any other part of the civilised world," and the "evil of forcing an alien language as serving to dry up at their sources the very fountain springs of national power," others, like Mr. Natarajan, of the *Social Reformer*, thunder against the least attempt to diminish the place of English in Indian education as an attempt to keep India in darkness, and would extend the teaching of English to primary education. The differences of opinion existing among

* Report of the Calcutta University Commission, Vol. II. p. 241. (Chapter on the medium of instruction and examination.)

Indians are found in equally acute forms among Europeans playing an important part in Indian education and Indian administration. The Rev. W. E. S. Holland, then Principal of St. Paul's Cathedral College, Calcutta, wrote: "To be educated in a language which is not the medium of thought must cramp intellectual development in all kinds of ways. The foreignness of our whole curricula sterilises our best Indian minds." But other Europeans of equally high standing think the increased use of the vernacular would be contrary to the best interests of the country. In Bengal, as a whole, the desire for English is not only strong, but increasing.

"The Secondary Vernacular School," says the Director of Public Instruction, "is no longer in demand. A knowledge of English is nowadays regarded as the first necessity of life—the doom of Secondary Vernacular Schools is, in fact, sealed."*

It is only by a great public movement that the current could be turned back.

22. The Commission hope to have found an eirenicon in the policy of bi-lingualism (it is strange how rare the term is in our evidence), a policy adopted by the educated classes in Wales, in large parts of Canada and South Africa in our own dominions, and in other countries like Switzerland and Belgium, which has not in any way, we believe, diminished the intellectual power of the inhabitants. We have come to the conclusion that while the vernacular should be used to an increased extent up to the matriculation stage and as the medium in all subjects except the teaching of English itself and of mathematics, the premature use of a foreign and half-understood medium has tended to produce intellectual muddle more or less concealed at matriculation by remarkable feats of memorisation; and we suggest that at that stage the use of English should be optional, except in the two subjects I have named. Beyond that stage, and especially in the first two years following it, English should be fully mastered, and it should be used exclusively in the highest stage except in teaching Oriental languages. That is the solution we adopt for the moment. In spite of the secular traditions of Bengali literature, in spite of the modern school, headed by the illustrious Tagore, we are convinced by Indian evidence that this vernacular, the most developed of all Indian vernaculars, is still unsuited for the highest teaching in Western subjects. May I quote here our general conclusion?

"We do not wish to prejudge the future. It is not for us to predict whether the natural desire to use Bengali to the utmost will eventually outweigh the immense advantages of being able to use a medium common not only to the educated classes throughout India, but to more peoples than any other, and giving access in effect to the literature and the scientific records of the world. We are disposed to think that the educated classes in India will, like those of some other countries, both in the British dominions and elsewhere, wish to be bi-lingual; to use their mother-tongues for those dear and intimate things which form part of life from infancy upwards, and which are the very breath and substance of poetry and of national feeling; to use English as a means of intercommunication necessary for the maintenance of the unity of India and of touch with other countries; for the mutual interchange and stimulation of ideas in the sphere of scholarship and science; and for the promotion of that inter-provincial and international commerce and industry on which the economic future of India will largely depend."

23. Before leaving the subject of medium entirely I want to touch on one point which concerns India, but not India alone. It is a point that has not been fully realised in Western education—the use of the mother-tongue as a means of mind-training, and especially for the stimulation of individual thought, of individual judgment, of the intellectual conscience of the pupil exercised even as against the teacher. In the greater part of school education the ultimate decision in regard to a piece of work rests, and must rest, with the teacher. There is little scope either for originality or for the exercise of really independent judgment. But if the mother-tongue is used as a means of mind-training, if the pupils are encouraged to write from time to time on subjects within their own experience, of which from their very nature they know not less but more than their teacher, and are encouraged to exercise their own powers of criticism on such work; if they are asked to write on a given subject, with a definite object for a definite audience; if they are then asked (with the help of the teacher and of the class) to criticise their own success or failure, but to be themselves made ultimate arbiters of whether or how far they have succeeded or have failed in their modest task, an entirely new element has been introduced into their education. I quote once more from the Report: "To pupils trained by such methods as we suggest, the printed document loses its magic authority: they have learnt for themselves what sincerity in writing means, and to be alive to the signs of sham and confusion of thought, whether in

* "Progress and Education in Bengal, 1912-13 to 1916-17," by W. W. Hornell, C.I.E. (1918), p. 29.

manuscript or print. In learning to judge the merits and faults of their own productions they have also learnt to judge those of others."

24. I have spoken of stimulating individuality and individual judgment. We now come to the machine which in India, to a far greater extent even than in this country, has tended to crush them out—the examination machine. With this subject (on which I spoke in this hall some years ago) I wish now to deal comparatively briefly. Our Report has, I believe, given a more complete analysis of the problems of an examination system than has been previously attempted. I shall illustrate one of its characteristics, so often and eloquently denounced, by a single example. A distinguished Indian told me that in his early career he had been asked a particular question, and knew that the answer was contained on a particular page of a particular book, but not exactly in which sentence, so he wrote out the whole page from memory; and he added that it was many years before he understood that his grievance against the examiner who ploughed him was not justified.

The survey of existing conditions we have summed up in these words :—

"It is impossible to peruse the evidence on the examination system as it exists to-day in Bengal without a feeling of profound sadness. The immensity of the effort, disproportionate to the results; the painful anxiety of the candidates; the mechanical award of marks encouraging the least fruitful efforts of the mind; a leniency sometimes neglecting the grave responsibility of the university to the public, and tending to class the less with the more deserving candidates; the number of failures in spite of that leniency; the sterilising influence of the whole system on both teachers and taught, and the consequent crying waste of the intelligence of the youth of Bengal—these are evils which have been brought home to us by the most convincing evidence from witnesses of every section of the community, as well as by what we ourselves have seen. These evils can only be eradicated by resolute and determined reform, accompanied by a change in the whole spirit in which the university institutions of Bengal shall be administered in the future." (Report, Vol. II., Chapter XVII., The Examination System, § 184.)

25. We have been criticised by some persons, who regard reform as synonymous with change in regulations, on the ground that our proposals for reform are not sufficiently detailed. We believe that no change in regulations will effect reforms without a profound change in the whole attitude towards examinations.

We have shown that the evils of the examinations arise very largely from their uncertainty of purpose. They are meant as a test. What do they, in fact, test? What can you certainly say of the persons who pass them? We have suggested that their purpose should be formulated in each case; that the design of each examination should be made to correspond to its purpose. From those general principles, if they are applied, the details of examination regulations and their rational interpretation by examiners will flow. To have set up a new hard-and-fast system would have been to replace an old rigidity which has tended to grow meaningless by a new rigidity which would soon become no less meaningless. It is only by asking again and yet again the question "What does an examination mean?" that it can be kept from sclerosis. In order to ensure that such questions shall not be forgotten, we propose new machinery (I hope the word will satisfy our critics), a new Examinations Board, whose business it will be to act as the auditors of the examination system and the wakeful conscience of the university in this matter; not an executive board, but an advisory board, with power to investigate examination results, statistically and in detail, and to publish for the information of the public typical examination answers. Such answers, I suggest, should be neither necessarily the best nor the worst; average answers, and especially border-line answers, just enabling a candidate to pass, are what the educated public and especially the body of university teachers as a whole should see from time to time, in order that the exact significance of a university diploma may be brought home to them. If I remember right, the inspectors of medical examinations appointed by the General Medical Council here give definiteness to their reports by the quotation of such answers as I suggest.

26. I greatly regret to see that the new Dacca University Bill and Statutes do not provide specifically for an Examinations Board of the kind we have recommended. I trust that the omission is only due to an oversight.

27. I have spoken of five factors which differentiate Indian from British education. There is another great factor which influences the number and character of the students who now crowd into the colleges of Bengal. At present, we were told by the Indian headmaster of a high school, "nearly all students who matriculate flock to the university without consideration of their individual bent, or their special talents, or their fitness for university training, or of their future life. . . . The majority of these students

are . . . unfit to receive university training." The ultimate reasons for this rush to the university are no doubt many and complex, but there is one simple fact that accounts for much.

28. At present in India, for the vast majority of Indians, there is only one way to a career, and that lies through the university. The Indian landowner and, in Bengal, the Indian business man, is born rather than made; the commerce of Bengal is mainly in the hands of a Rajput community (the Marwaris) and the Europeans. The varied careers of commerce and industry, for which the passing of an examination is not required, and which lead in Europe to the highest positions in the community and in public life, are only beginning to open out in Bengal.* Broadly speaking, if you wish to make your way by your talents and energy in Bengal, you must go through the university mill, and the way to the university is through the high school, a fact which now seems to be known even to labourers' families throughout the Presidency.

29. Hence an excessive pressure on the high schools and the universities, a pressure increasing daily, of which even the post-war pressure in England scarcely gives us an idea; hence the multiplication, growing daily, of secondary schools, run for private profit, with inadequate and miserably paid staffs, dirty, dingy, overcrowded; hence colleges of the university with inadequate and unused libraries, 1,500 or 1,600 students crowded into a few lecture-rooms, sometimes forced, by want of accommodation, to go into the streets between lectures, receiving instruction of which the be-all and end-all is the passing of the examination. Training indeed, but training that deforms the intelligence and weakens the mental powers of Bengal. If I have described the worst, it must not be taken that this describes the best. Some of the colleges, notably the Presidency College in Calcutta and Dacca College—which are Government colleges—and some others, would in many ways be an ornament to any university, and Calcutta and all the other important university centres in India are now active centres of research. But the serious element in the situation is that while the Government colleges and a few others resist the pressure of numbers, the pressure is growing, and that with the increasing demand for education, unless drastic measures are taken, the education itself will grow not better but worse.

30. Let me give a few figures. From 1912 to 1918 the number of students enrolled in the "arts colleges" in the University of Calcutta increased from 10,980 to 18,478, an increase of 68 per cent. in seven years. During that period the number of pupils in the English-teaching secondary schools of Bengal increased from 260,000 to 378,000, or 40 per cent.

31. We have thus a system feverish, strained, mechanical. To some of our advisors the remedy has seemed as obvious as the facts. "There are too many students in the universities and the high schools for efficiency. Diminish the number." We have regarded that advice as irresponsible advice. You cannot deal with a great popular movement by simple denial in that way. We asked ourselves, instead, at what point could new life be most effectively infused into the whole organisation.

32. It has long been apparent to those concerned with Indian higher education that the work of the first two years in the university was probably its weakest spot. To give instruction through the medium of English to youths of whom a large number cannot understand the spoken language; to lecture to youths whose sole idea of taking notes is to copy down verbatim, and who, even if they do understand English, are so little trained mentally that they are unable to distinguish what is essential in a lecture from what is merely accessory; in a word, to base your methods of instruction on hypotheses which are obviously untrue; this could only lead to failure in teaching and failure in examinations on a large scale, if the examinations were not to be a farce; and both the intermediate examinations themselves and the number of rejections have been serious. It was clear to our predecessors, the Commission of 1902, that the "second-grade colleges," as they are called, which provide only this two years' course, without the additional two years' course, were unsatisfactory. They proposed that they should be abolished. We recommend that they should be improved, separated from the university system, and reconstituted.

33. We thus propose to increase the minimum age for entrance to the university from sixteen to eighteen (or seventeen in exceptional cases), a proposal which, I gather from the Indian newspapers, has been welcomed generally, if not universally, all over India.

But that change implies others, both above and below the level of university entry. I deal

* In Bombay the case is different. There are large Indian firms belonging to the Hindu as well as to the Parsee community.

first with the changes below the university level; for improvement below this level is a necessary antecedent to any really great improvement in the university itself; and those changes must be of two kinds—administrative and educational.

34. We propose that secondary education and the education of the two years to which I have referred, which might be called "higher secondary," but which for the sake of convenience we have called "intermediate education," should be transferred to a new authority—"The Board for Secondary and Intermediate Education" — consisting of from fifteen to eighteen members, of whom seven would be university representatives, one elected by the non-official members of the Legislative Council of Bengal, and the remainder appointed by the Government of Bengal.

Other important points in the constitution are that there should be a salaried chairman; that the Director of Public Instruction should be an *ex-officio* member; that there should be representation both of Hindu and Musulman interests (by not less than three members each), and representation of experience in agriculture, industry and commerce, medicine and public health, teaching in intermediate and secondary schools, the education of girls, and the education of the domiciled community; and finally, that a majority of the board should be non-official, *i.e.*, consist of persons not in receipt of a salary paid directly by the Government.

We should have much preferred a board of from five to seven members, but the diversity of interests and educational needs is too great to be adequately represented by so few.

35. To our Board we should entrust a substantial measure of control over Government secondary and intermediate institutions, the "recognition" for the purposes of matriculation (which we re-name the High School Examination) and of the intermediate examination, of all high schools and intermediate colleges, and the definition of their curricula, the inspection of such schools and colleges, and, subject to budget control, the making of grants to those institutions. Two of our colleagues—including our Musulman colleague—dissented in regard to the last two points.

I believe that important members of the Muslim conmmunity think that in the matter of grants and inspection they would receive more favourable treatment by a Department of Public Instruction than by the Board. I regret that view, as I believe the dual control which they propose would make the business of the Board more difficult to conduct; but this is, after all, a matter which could be adjusted.

36. The Board is only a means to an end—the improvement of this two years' course, on which the efforts for reform can be most effectively concentrated, as well as of secondary education generally. We have suggested that (say) thirty "intermediate colleges" should be provided in Bengal for this purpose—of which some would be the present "second-grade colleges," some would be existing "first-grade colleges," which decided to devote all their energies to this important intermediate work, and others, again, would be attached to existing Government high schools. Thirty such institutions is a manageable number. You cannot in any short time deal with the 700 high schools of Bengal; you can do much to supplement the defects in their teaching by effort in the thirty colleges to which their best students would proceed.

37. The new intermediate college will have a double purpose—(1) to prepare better than heretofore the students who desire to enter the university; (2) to prepare others for various practical careers of a kind for which university training is not needed—many branches and grades of industry, commerce, engineering, and agriculture, primary teaching, and the lower branches of Government service. It is clear that Indian commerce and industry are developing; they may be expected to absorb at an early date a largely increased number of youths with a sound practical education.

38. We propose for these colleges a varied curriculum, and suggest only three subjects as compulsory for all students. First, practical English, to be taught in relatively small classes and by methods far more modern and efficient than the wasteful ones hitherto adopted.* Such teaching should, at any rate for a time, be directly guided by English teachers. Secondly, the vernacular, with better teachers and better methods, not only for its own sake, but as a means to clear thinking. Thirdly, physical training, with good recreative facilities.

For those students who definitely intend entering a university we suggest a choice of four additional subjects, selected from some such list as the following:—(1) a classical language; (2) history; (3) geography; (4) English

* A Bengali boy devotes in the four upper classes of the high school on the average about twelve hours in school and fourteen out of school to learning English, with the average results stated above. There are, of course, many exceptions in the thousands of pupils.

literature; (5) logic; (6) economics; (7) mathematics; (8) physics; (9) chemistry; (10) biology.*

Students destined for arts, science, or medicine would all find the necessary elements in such a course. For an engineering student a higher standard of mathematics and mechanical drawing would have to be added; for agricultural students, land-surveying, an introduction to the principles of agriculture, and some training in book-keeping; for commercial students, commercial geography and accountancy; for teachers, some introduction to the art of education and perhaps some teaching practice.

39. Clearly the intermediate colleges ought to be of different types; and any one ought only to supply a small number of alternative courses, if the numbers are to be kept within the limits necessary for efficiency. The recent dictum of "each one different from the last, each one better than the last," has as much to be said for it in designing colleges as in designing ships, and with this advantage, that, unlike a ship, an obsolete college can be reconstructed instead of being scrapped.

40. It should be an essential part of the intermediate college course that the teaching should be given by school methods as far as possible. It is the give-and-take method of the best schools with daily control of each boy's work that is needed at this stage—not the looser control by the teacher, the greater responsibility of the student of the university. I do not mean to suggest that the Indian boy is idle; in many cases he works far too many hours. I have questioned many boys in many schools and many colleges. It is a common thing for Indian boys of from twelve and thirteen upwards to be at their lessons or books ten hours a day, and to work on Sundays as well as in the week, a practice which is only compensated for by the large number of holidays, both Hindu and Muslim holidays being observed as well as the major English holidays. But much of this work is unsystematic and undirected, or devoted to mumbling aloud passages to be learnt by heart. The buzz in a hostel, when many boys or students carry on this practice simultaneously is a thing not easily forgotten.

A correlative of the proposal that school methods should be adopted is that the pupils should be of school age. The substitution of the vernacular for the English medium in most subjects of the high school course should greatly accelerate progress through that course, and gradually diminish the average age at the "matriculation" stage.

41. One of the great advantages of the new system would be to prevent Calcutta, which already has 15,000 students, from being flooded by youths who need school instruction and discipline; for the majority of the intermediate colleges would be in the *mufassal*.*

42. I now come to the university stage, which, again, requires reform, administrative and educational. I do not want to weary this audience by a detailed description of the constitutions we have recommended for the Universities of Calcutta and of Dacca. Our general aims may be expressed very simply—it is to enlarge their responsibilities and their powers. The provincial Indian universities have been created by acts of the Imperial legislature; the great majority of the supreme governing bodies, or senates (as they are called) are appointed by the Chancellor, who is invariably the head of a Government; the bulk of the funds required for the conduct of their work, in addition to the fees paid by students, is supplied by Government (in Bengal between one-third and one-half of the total cost); the character and equipment of the teaching institutions which prepare students for university examinations are in the main determined by Government.

In the case of Calcutta it is not by the Government of Bengal, but by the Government of India, more than 1,000 miles away, that the University is largely so controlled; the sanction of the Government of India would be required to add an examination paper in English, or Sanskrit, or mathematics at the B.A. examination.

The changes we propose are all in the direction of giving greater autonomy and responsibility to the universities. Entire autonomy was advocated by scarcely any of our witnesses. In a country where racial animosities have existed for so long, all parties feel that Government, which is, on the whole, regarded as impartial as between Hindus and Musulmans, must retain more control than might otherwise be necessary. But at every point we have tried to safeguard Muslim interests by providing for their representation on university boards, and by providing a special advisory board to look after them. Having regard to the backward condition of

* I have not followed here the exact order or text of the Report.

* The name conveniently given in India to the portion of a province or presidency outside its capital.

the Muslim community, every reasonable means must be taken to encourage Muslim students.

43. The constitution which we recommend is somewhat analogous to that of the English provincial universities; we propose a large representative court, with greater control of finance than the corresponding courts of English universities; an executive council; and an academic council, faculties, and boards of studies as committees of those faculties. While the constitution in its fundamental points will be settled by Act as heretofore, and statutes should, as in this country, be only alterable with public sanction, minor alterations of ordinances and regulations may be made by the university itself, though ordinances should be subject to the veto of the Chancellor.

44. We think the system of having in one city a number of isolated and independent colleges, all doing work of exactly or almost exactly the same pattern, is a bad one. For a small city like Dacca we recommend that the teaching should be placed entirely in the hands of the central university authority. In Calcutta, where there are twenty-five colleges (with some of the best of them on a sectarian basis), but where recently nearly all the post-graduate work has been taken over by the university, such an arrangement would be impracticable, and a new kind of synthesis is necessary. The colleges must be brought into closer touch both with each other and with the university bodies, on which they have hitherto had no direct representation.

45. One of the features of university organisation in India is the considerable number of isolated colleges in country towns, the majority with totally inadequate resources, giving university education in name; in reality, preparing only for university examinations. There is perhaps less reason in Bengal for such dissipation of energy than elsewhere. The Bengali boy who, owing to the dispersion of the population in villages rather than in towns, rarely finds a college within reach of his home, is just as ready to travel two hundred miles as twenty; and hence a concentration of resources in a comparatively small number of centres, provided with an adequate variety of teaching, adequate libraries, and adequate laboratories—centres of a kind likely to develop ultimately into universities—would be all to his advantage. Nothing is more depressing in Bengal than to see the uniformity of model and inadequacy of resources of the numerous colleges in the *mufassal*, although many of them contain excellent teachers whose value would be doubled if they could be brought together.

The creation of such potential universities would not, under our plan, leave the districts educationally derelict. We hope that the intermediate colleges may become living centres and develop, by means similar to those of our University Extension movement, some form of adult education, a subject of which the full importance is only just being recognised at home.

46. In the Universities both of Calcutta and of Dacca we propose to set up a new organisation to deal with the education of *purdah* girls and women—a subject that can only be effectively dealt with by the co-operation of women who are themselves *purdah*. We have been criticised both for going so far and for going no further. I think that while we have not underestimated the immeasurable importance or the urgency of the problem, we have done well to stay on the threshold, and only to point to methods by which it may be solved. As I have said above, Indian universities have long been open to the small number of women willing to attend them.*

47. So much for administration. On the educational side we propose two main reforms—the extension of the present two years' post-intermediate course to a three years' course, and the introduction of a system of tutorial and individual teaching and of individual work, especially for arts students taking honours, to supplement mass-lectures.†

It seems scarcely necessary to add that we desire large increases of the teaching resources and equipment for research of the universities; but this is a demand common to all universities all over the world. We are clear, from our experience, that the universities of Bengal will be able to make good use of them. One of the most important of needs is a strongly organised University Department of Education, which will be alive to the new ideas springing up in all parts of the world, and able to put them to the test of experience, under Indian conditions, and on a small scale before applying them on a large scale.

48. At this turning-point in the history of India, the part that the Indian universities will play can scarcely be exaggerated. It is hardly

* Only a small number of the colleges admit women; provision is generally made for them in special colleges.

† At present in Calcutta honours students have less time for individual work than pass students. They attend the pass lectures and others in addition.

too much to say that India's political and social future depends on her universities. I know that many thoughtful people in Bengal do not under-estimate the burden of responsibility that will fall on them.

For the adequate design of secondary education and the training of secondary teachers, suited to India's needs—one of the first tasks to which they will have to apply themselves—they will be directly responsible; for the design of primary education and the methods of training primary teachers, suited to India's needs, they will be at least ultimately responsible; and the problem of primary education in India is the largest educational problem now before the world. All that we can do in strengthening university and secondary education is only a preliminary to the solution of that last problem.

The Montagu-Chelmsford Report insists on "the immense work of education to be done throughout the countryside," on the necessity of wakening the Indian ryot's intelligence, of helping him to be "an independent, self-determining man." I think no one can face the task, and really understand it, without a feeling of something like awe at its difficulty, its immensity, its dangers.

The conditions of India, with its literate middle class, or *intelligentsia*, as the Montagu-Chelmsford Report calls it, its illiterate peasantry, are in some respects ominously like Russian conditions in the past which have led to the destruction of that *intelligentsia*. Fortunately, under British rule, other conditions have been very different; and, if we may trust Hunter and other observers, the Indian peasantry is very different from the Russian peasantry, described, before the war, in such gloomy colours by Tolstoi and Gorky, and other modern Russian writers.

But we have to remember that if education is to mean, as it has too often meant, literacy and nothing more, we shall be merely sensitizing an impressionable people, making them capable of reading without judgment. In the West propaganda has become a threat to stable institutions: in the East it may become a greater threat. How shall it be averted? How shall you make your education mean "training," and a social training so designed that the movement of India shall be a steady movement? Education is not itself the original cause of that movement; it comes from the spirit of the times and the rumour of the market-place; it cannot be kept out by frontier-guards or Government regulations; and the desire for education has spread to the *namasudras* of the north, to the untouchables of the south. But if education did not create that movement, I believe that it can guide it.*

49. I come to my last topic, not the least delicate. To be dealt with satisfactorily it must be faced with perfect frankness. How far will Europeans continue to play a part in Indian education? Mr. R. P. Paranjpye—the distinguished Principal of Fergusson College, Poona, and a former Senior Wrangler†—and many of his countrymen suggest that Europeans will soon only be needed for a few of the highest posts, and that India should follow the policy of Japan, who started her educational organisation by employing Europeans, but has replaced them entirely by Japanese trained in the Western countries of Europe and America. It is a natural and intelligible policy. But I am inclined in the first place to doubt, from what I have heard, whether Japan has not lost more than she has gained by its too rapid adoption, and, secondly, it seems to me to overlook the differences between India and Japan.

Japan is our very good ally. India is a country of the British Commonwealth, and, except for a handful of extremists, desires to remain so. India desires not Japanese institutions, but institutions modelled on those of Great Britain and developed to meet Indian needs; and though it is not vocal, there is among the *bhadralog*, the middle classes, a strong feeling that they have something direct to learn from Englishmen and other Europeans which is not testified to by university examinations and distinctions.

50. The success of the missionary colleges all over India is a proof of this. Many of those colleges—the great majority—make no attempt to proselytise, and I believe that some of the largest have only a handful of Christian students. It is for the example set by the teachers, and the whole spirit which they create, that pious Hindu

* One may look forward with some hopefulness to the Indian Y.M.C.A. efforts to link education with the co-operative movement, started, like so many other important movements, by Lord Curzon's Government, and to the investigation on missionary village education now being conducted by the unofficial Commission presided over by Mr. Andrew Fraser. The suggestion made by Dr. Henry Whitehead, the Bishop of Madras, that, departing from Western precedent, the education of the village should be begun by the education, and especially the technical education, of the adults, so that the children will grow up to take their places in an educated village, seems especially promising.

† I refer to his presidential address delivered at the Bombay Educational Conference held at Surat, as reported in *The Collegian* (Calcutta) of November 1st, 1919.

and Muslim fathers, jealous to the last degree that their children's faith shall be untouched, send them to missionary colleges, to be trained by Englishmen and, I must add, by Scotchmen—who have played so immense a part in Indian education—and by Belgians. All over Bengal I came across Indian parents who wished to send their sons to the Scottish Churches College, to St. Paul's Cathedral College, to St. Xavier's. "I want them to be under the influence of the missionaries," was a common expression; so was its variant, "I want them to be educated by Englishmen." It is less the unofficial teaching to which some Indian Chauvinists object than the official; yet Presidency College, the largest Government college, with the greatest number of European teachers (in peace-time), has the pick of the Calcutta students and turns away hundreds every year.

Indeed, I believe, if analysed, the objection in India is largely, not to European teachers, but to the present system of the Educational Service. It is a service which has secured to India many admirable teachers in the past, but I believe it must be gradually transformed into a different system—a system of *ad hoc* appointments, under which Indian institutions will feel that they are getting the best man available for each particular post, whether Indian or British. A larger number of first-rate men would be tempted (as they ought to be tempted) to go to India if they felt that by so doing they were not necessarily committing themselves for life.* India is nearer to us than it has ever been. There is no reason why good work in history, chemistry, or physics done in Dacca or Calcutta should not be as well known to historians, chemists, and physicists in Great Britain as work done in Glasgow or Manchester. Yet it is to be remembered that the field for Englishmen of enterprise has grown larger, and India may find their services more difficult to secure than in the past.

51. I have tried to see this matter from both points of view. The old tag of Mr. Kipling's, "East is East and West is West, and never the twain shall meet," has a context which is not often quoted. It provides a meeting-place for the brave of all races. In the War men of the East and of the West have fought together for a new and high ideal. I am one of those who regard a new departure, sanctioned or about to be sanctioned at this historic moment by Parliament, as the only way to safety in India. But those who look on the situation as in itself an easy one or a safe one must be indeed ignorant or devoid of imagination. It is one that needs high courage for all concerned; a common-sense and decision less common in India than the logic of the schools; the *esprit de finesse*—I will translate the phrase boldly by "sense of reality"—which the high-souled Pascal demanded of the thinker, as well as the *esprit géometrique*, the mathematical sense, in which so many Indians excel; and, lastly, the stern power of saying "No," in the public interest, where it would be easy and gracious to assent.

I believe profoundly that in the new education of India the need for the help of Englishmen, strong of heart and mind, will be great. I hope that Englishmen will give that help. I hope that India will welcome it.

May I end on a personal note? I feel how much I owe in my experience of India to two Indian colleagues, Sir Asutosh Mookerjee and Dr. Zia-ud-din Ahmad, whom to know is to admire; and I desire to express my appreciation, not only to them, but to the other teachers and administrators, Indian and European, who have striven to redeem a faulty system by loyal co-operation and by personal service and ability of a high order.

I am conscious of the imperfection of this sketch, in which I have set myself rather to point out what remains to be done in Indian education than what has already been achieved. It would be still more imperfect if I did not say that, in spite of what I have seen, and because of what I have seen, I have faith in the educational future of Bengal and of India.

DISCUSSION.

THE CHAIRMAN (Sir William Duke) said that after the extraordinarily interesting and eloquent paper which had just been read, he was sure they would all appreciate the main outlines of the great educational problems of India. They would also be satisfied that, in view of the work which had been done by the Calcutta University Commission, the authorities who had in future to make decisions on educational matters would have very clear guidance before them. Lord Meston's absence was especially unfortunate, because he could have given them his opinion on what lay at the root of all progress, finance; he was one of the greatest authorities on Indian finance. The educational burden which the ratepayers of Great Britain had to bear had increased of late years, but even at the maximum which had been attained they could not

* The substitution of a system of tenure for a given number of years with a retiring bonus instead of life-tenure would be a useful and important innovation. It has been recommended for certain cases by the Calcutta University Commission.

pretend that their teachers were well paid and that the remuneration accorded well with the dignity of their profession. The Primary School teachers in India worked under miserable conditions, and it had been a keenly discussed question between himself and some of his Indian friends as to whether quantity or quality was the more important. Both were most urgently required. The expenditure on education in India would have to be increased enormously, and in that connection he would have liked to have heard Lord Meston's views as to what proportion of that increase could be borne by the Government and what proportion should be found by the voluntary efforts of the people, though it really came to the same thing in the end; the money had to be found by the people either directly or through their agent, the Government. Another point to which he would like to refer was the interesting controversy as to the language which should form the medium of instruction. As a result of his experience and observation in India, he thought that whichever system was followed — whether instruction was given in the vernacular or in English—the essential thing was that the language chosen should be thoroughly acquired and be the medium of the student's thought. The pupil should not be hampered by having to struggle simultaneously with the difficulties of a subject and the difficulties of the language in which that subject was taught. One hundred and fifty years ago it would have been unthinkable that instruction in Western subjects could be given in the vernacular, just as in the thirteenth century it was unthinkable that education could be given in Western Europe through the local dialects of that period. He believed, however, that there was no great advance in Western Europe until education ceased to be given through the medium of Latin and began to be imparted in the vernaculars, which by that time had become fit media to convey it. That either pointed to a day when the rapidly-improving Indian vernaculars would have become flexible enough for the purpose, or to a time when English would be taught so early and thoroughly in India that the children would be bi-lingual. Indians would have to make up their minds in the future to what extent they desired the help of Englishmen in education. On the whole, he was sure that there were certain subjects, or rather purposes, for which Indians would not willingly relinquish the advantage of having the best brains of the English universities to help them; and he hoped that no career would appear more honourable to the young men of our universities than that of assisting in the progress of education in India.

THE SECRETARY of the Section then read the following extract from Lord Meston's letter: "My interest in Indian education is very great, as must be that of anyone who has been associated with the recent administration of the country. An enormous amount of valuable work has been done, but we are still on the threshold of the great problems which Mr. Hartog and his colleagues have been endeavouring to solve. It seems to me that the time has come for the establishment of a great National Trust in which the generosity of India and its friends should be mobilised to provide at least some part of the vast funds necessary for wise progress and adequate liberality to our schools and colleges. It would provide a much-needed means by which State aid could be supplemented and private enthusiasm could be enlisted in the directing and influencing of educational progress. I think there is room for such an organisation without any conflict with the sphere of the universities or of the Government, and it seems to me almost an inevitable concomitant of the coming constitutional changes."

MR. H. R. JAMES, M.A., late Principal of the Presidency College, Calcutta, said that when he first heard in 1917 that the Calcutta University Commission had been appointed he had wondered if it was not rather superfluous. He remembered the Indian Universities Commission of 1902, and he thought that the results of that Commission, which were embodied in the Universities Act of 1904 and the new Regulations of the Calcutta University, had given them tasks which it would take many years to work out; and as the new ideals and standards only got into full working order in 1910, it seemed that they had not yet been given a fair chance. He had begun to change his mind when he learned of the *personnel* of the 1917 Commission: Sir Michael Sadler was an ideal President, and in Mr. Hartog he knew the Commission would have the services of a man who talked more sense about examinations than anyone else he had ever heard. He (Mr. James) had been completely converted when he obtained the five volumes of the Commission's report; and if that had not quite converted him he would certainly have been converted by the admirable and lucid paper which Mr. Hartog had read that afternoon. He entirely agreed with the division between school and college education which the Calcutta University Commission had advocated, but he felt some doubts about their intermediate colleges. He doubted whether two years of instruction would suffice for that social education which every school and college ought to give. The 1917 Commission mentioned that the Commission of 1902 desired the abolition of what were called the Second Grade Colleges. He did not know whether Mr. Hartog had ever come across the reports of the two Commissions of 1905-06—Commissions which had inspected the colleges under Calcutta University. The suggestion was made in one of those reports that the Second Grade Colleges should not be abolished, but amalgamated with the High Schools out of which they had originally been formed. He still thought that was the best solution of the problem, although it had been considered and put aside by the Calcutta University Commission.

He quite agreed that it would be impossible to convert all the schools of Bengal into schools of that higher type, but the number of intermediate colleges suggested was only thirty, and he thought that thirty, or even fifty, of the schools could be converted; the gain to school education would be very great. It was said that education in those new institutions was to be by school methods and the age was to be the school age; perhaps then it would be well to make them completely into schools and call them "Collegiate Schools." Dealing with the question of the Intermediate Board, he quite recognised the gain that would be secured if a new Educational Authority could be set up which would have the full support of public opinion, but he noticed that the powers which were to be made over to the new Board were tremendous. It would take over a large number of the powers at present vested in the Education Department, the Universities, and the Government, and particularly the great financial power of the distribution of all grants. He rather doubted whether from fifteen to eighteen persons of the required competence and leisure—for apparently they were to be an unpaid body—could be found to undertake these vast responsibilities. He welcomed Mr. Hartog's remarks on the meaning and purpose of examinations. Examiners should always bear in mind that an examination was only a means to an end. He also agreed with Mr. Hartog on the language question. He had once ventured on the paradox that English was the vernacular of higher education in India. There was salvation to be hoped for from the blessed word "bi-lingual." Although a time would come when Bengal would be able to provide all the teachers that were necessary for its people, he did not think that time had yet arrived. The best successes of education had been won in the past through the co-operation of Englishmen and Bengalees, and he thought that would continue to be the case for some time to come. He was greatly pleased with Mr. Hartog's accurate reference to Kipling. His lines were too often quoted in a sense just opposite to their true significance; what they signified really was the oneness of East and West in all essentials.

Mr. Bhupendranath Basu said he was glad to be able to join with the previous speakers in expressing his appreciation of the valuable work which had been accomplished by the Calcutta University Commission. In view of the difficulty of the subject with which that Commission had dealt, it would have been impossible for them to have expressed their views in a more condensed form; and although their five-volume report required time to assimilate, there were many men in his province—Bengal—who would devote their attention to the perusal of it. If it had been possible, while the Commission was still in India, to have a series of lectures like the one which Mr. Hartog had given them that day, delivered say in the town hall of Calcutta, he thought their labours would have been better appreciated in India; because it was not very difficult to get hold of particular portions of the report which were not altogether agreeable to Indian sentiment, and use them to create misapprehension in the public mind about the labours of the Commission. Indians had now got to face the problem of education, and they were not dismayed at the vastness of the problem. They realised that the importance of the work demanded the thorough investigation which had been given to it by Mr. Hartog and his colleagues. He had been preceded in the discussion by his old friend Mr. James, and he would like to express to him the deep regret that was felt in Bengal at his early retirement from the education service; he had done invaluable work, and his loss was deeply felt. He had mentioned that because it bore on the point raised by Mr. Hartog as to whether the help of Englishmen was still required in education in India. He was one of those who thought that their co-operation and assistance were still required. He did not mean to imply that Indians were incapable of taking charge of their own education—if that was so, they would not be fit to receive the new powers and responsibilities with which they were to be entrusted; but he had always felt that the best places where the minds of India and England could meet and work for their mutual benefit were the colleges and universities of India. There they were removed entirely from political questions and considerations of a political character. English professors and Indian students met, not as members of different communities, but as members of the same body, the educational body of India, inspired by the same ideals and working harmoniously towards a common end. In his student days there were no Indian teachers in their colleges, but only Europeans; and he had the liveliest sense of gratitude for the many advantages he had derived from association with those teachers. He had learned to appreciate what was best in both English and Indian life; and having regard to the peculiar position which India occupied as part of the great Commonwealth of the British Empire, to which they were proud to belong, he did think that that constant and intimate association, in a domain other than political, was fraught with the greatest possibilities both to India and England. He would, therefore, be sorry to advocate a policy which involved the complete dissociation of English educationists from the work of Indian education, and he hoped that the new conditions which would shortly be introduced into the Indian Educational Service would attract the best products of the English universities. With regard to the question of the language in which education should be carried on, he thought that at the present time higher education in India could only be conducted in English. The ancient position of India as an isolated country, cut off from the rest of the world by mountains and the sea, had gone for ever.

They wanted to be in touch with the intellectual movements that were going on outside India, and the only vehicle by which that could be done was the English language. Possibly some other European language might answer the purpose, but it was well known that English was becoming an almost universal language amongst educated men, and therefore it was incumbent upon Indians, quite apart from all political considerations, to be able to express their thoughts in English, and to understand English without an effort, and that result had been achieved. For an educated Indian, an English mathematical or historical book was as easy to understand as it was for an Englishman. In spite of the high perfection which the Bengal vernacular had attained, they had not yet got a vernacular in India which could give expression to metaphysical, mathematical or scientific subjects without borrowing from Sanskrit, and if that was done the words became as difficult as foreign words. Indian young men were keen on learning not only English, but other European languages; they had got a philosophical turn of mind, and wanted to learn German so as to be able to read Kant in the original, and they also wanted to learn French. He did not think, therefore, that for higher education in the universities bi-lingualism would be at all helpful. The true solution was that up to a certain age the education should be entirely in the vernacular, and after that age was passed English should be gradually introduced, so that by the time a boy reached the university standard English could be the sole medium of his education. The solution of the problem of secondary colleges was not, in his opinion, the solution which the Commission recommended. The present Matriculation standard of their universities was much too low and elementary. Boys began specialisation immediately after Matriculation, and as a result a boy who had taken his M.A. in mathematics might not know a word of history or any geography at all. The true solution was to advance the Matriculation standard, and the present minimum age of sixteen ought to be advanced to eighteen; specialisation should not begin until the university standard was reached. That was a practical solution. He would conclude by adding his testimony to that of the distinguished and appreciative audience to the lucidity and ability with which Mr. Hartog presented the salient features of university education in India.

Sir George W. Forrest, C.I.E., said forty-nine years had passed since he commenced his official career by entering the Bombay educational service. During the fifteen years he had the honour of belonging to the Indian Educational Service he had enjoyed varied experience, and had found as a rule that greater success was attained when the students lived in college, as was the case at the Deccan College. With reference to the question of English teachers in India, the great work which had been done by eminent English professors in the past ought not to be forgotten, and he thought it would still be wise to utilise the services of a certain number of Europeans as pioneers of higher education. It was, however, becoming increasingly difficult to obtain the best men for the work, owing to the multiplication of openings at present available for Englishmen of initiative and resource. It was not so much the actual teaching as the coming into contact with the Indian students which was so valuable. It would be hard to exaggerate the influence which Wordsworth, Oxenham, Selby, and Macmillan had in moulding the character of the students, who would be a credit to any university. When he went to Calcutta he thought one of the great drawbacks of the Presidency College there was its distance from the European quarter. In Bombay, happily, that was not the case, and the constant intercourse between Indians and Englishmen who were united by a love of letters was a great benefit to the University. He was delighted to hear of the impending doom of the Matriculation Examination, which had, he thought, done more injury to Indian education than anything else. People came in shoals to take that examination, although they were totally unfitted for it, simply because it was a passport to Government service. It would be an impertinence on his part to compliment Mr. Hartog on his paper, but he hoped it would lead all who heard it to read the first two volumes of the Commission's report. He had read a large number of blue-books at one time or another, but he did not think he had ever read a more statesmanlike report than that which Sir Michael Sadler and his colleagues had drawn up. He did not agree with it in all particulars, but he did think it was one of the finest reports that had ever been printed, and he hoped one day to be able to suggest to Mr. Fisher, in order to make them realise what was the true aim of education, that portions of it should be printed and circulated to teachers at home and our university dons. He had great pleasure in proposing a hearty vote of thanks to Mr. Hartog for his paper.

The vote of thanks was seconded by the Chairman, and carried unanimously.

Mr. Hartog, in reply, said that in view of the lateness of the hour, he would deal in writing with the suggestions that had been made with reference to the Indian colleges. He would like to tell them an experience he had had in one of the Bengal colleges. He had listened to a lecturer speaking on an English text. He spoke for the full hour allotted to him at a very rapid rate, and after the lecture was over asked him (Mr. Hartog) for his opinion on it. He told him that in England or France the pupils would have done at least half of the talking in asking or replying to questions. A short time after he received a letter from the lecturer, which ran somewhat as follows: "I thought over your suggestion, and decided to try it

in my first and third year classes. I dared not try it in my second and fourth year classes, because the pupils might have failed in their examinations. In the first year classes I got no result, because the pupils were incapable of asking any questions, but in the third year class they asked me questions one of which I was unable to answer. When I was lecturing on 'Paradise Lost,' a student asked, 'Why does Milton put into Adam's mouth the expression "in my mother's lap?"'" It was somewhat remarkable that it should have remained for an Indian boy to discover that anachronism.

[NOTE.—In accordance with the suggestion of the Secretary I put into writing a few remarks arising out of the preceding discussion. I welcome most heartily Lord Meston's proposal for the foundation of a great National Trust for education in India. Such a Trust, if administered with the help of expert opinion, would be especially valuable in assisting new ventures of existing educational institutions, as well as new foundations in their early years. I hope that Lord Meston's important proposal may be taken up in India by the wealthy and public spirited men to whom it should appeal. The news of Sir Rashbehary Ghose's recent gift to the University of Calcutta of over 11 lakhs of rupees (say £130,000), added to his previous benefaction, is of good augury for the future. The criticisms which Mr. H. R. James has added to his generous praise of the work of the Calcutta University Commission clearly deserve attention. Mr. James thinks the two years' course proposed for the Intermediate Colleges too short to impart the "social education" which ought to be given by a school or college. That point was put to the Commission by the Rev. Garfield Williams, another experienced head of a college, and the Commission also considered the reports referred to by Mr. James. The Commission has proposed that in certain cases the Intermediate Courses should be added on to the top classes of the existing high schools (the lower classes receiving possibly a separate organisation), but it was impossible to propose such a scheme for universal adoption. The existing "Second Grade" Colleges, and those "First Grade" Colleges which decide to limit themselves in future to intermediate education cannot be left out of consideration; moreover, for geographical reasons, it may be desirable to establish new Intermediate Colleges in places where there are no suitable high school classes at present to combine with them. It seems to me personally that at a later stage it may be possible to add on one or two high school classes to all the Intermediate Colleges which do not possess them, and so to meet the views of Mr. James and Mr. Garfield Williams, for which there is much to be said. I fear that I cannot in the brief space at my disposal deal with Mr. James's doubts as to the powers to be conferred on the Board of Secondary and Intermediate Education. Every scheme of this kind must necessarily be of the nature of an experiment, just as the foundation, some thirty years ago, of County Councils in this country was of the nature of an experiment. We had placed before us, very fully, doubts similar to those expressed by Mr. James, but we believe the scheme which we propose to have a greater chance of success than any other which was proposed or which occurred to us. I desire finally to say that though I hope that in those portions of my paper and of this note which deal with the work of the Calcutta University Commission I have reproduced the views of the Commission accurately, I must not be regarded as their official spokesman.—P. J. H.]

CORRESPONDENCE.

POWER FROM THE SUN.

Referring to the subject of Mr. Campbell Swinton's letter on pages 94 and 95 of the *Journal* of December 26th, may I point out that quite a small child can gently press against a heavy open door, and so close it? But a rifle bullet fired at the door would go clean through it without moving the door at all, unless the latter were ironclad or protected by a very thick covering of yielding material, such as we use in ballistic experiments.

The problem is to find the armour or "sandbag" on which solar radiation may be made to do useful work.

W. H. MASSEY.

GENERAL NOTES.

THE MICROSCOPE: ITS DESIGN, CONSTRUCTION, AND APPLICATIONS.—The Faraday Society, the Royal Microscopical Society, the Optical Society, and the Photomicrographic Society in co-operation with the Optical Committee of the British Science Guild, meeting in joint session, will hold a symposium and general discussion on "The Microscope: its Design, Construction and Applications," on Wednesday, January 14th, 1920. The meeting will be held in the rooms of the Royal Society, Burlington House, Piccadilly, W. 1 (by kind permission of the President and Council), and it will extend over two sessions: from 4.30 to 6.30, and from 8 to 10 p.m. The meeting will be presided over by Sir Robert Hadfield, Bart., D.Sc., D.Met., F.R.S., President of the Faraday Society, who will deliver an opening address, and Mr. J. E. Barnard, President of the Royal Microscopical Society, will then give a general survey of the subject, and he will be followed by Sir Herbert Jackson, K.B.E., F.R.S. Professor F. C. Cheshire, C.B.E., will then speak on the Mechanical Design of Microscopes, and a paper by Professor A. E. Conrady, on Microscopical Optics, will be presented. Further particulars may be obtained from F. S. Spiers, Secretary, The Faraday Society, 10, Essex Street, London, W.C. 2, or C. J. Lock, Secretary, The Royal Microscopical Society, 20, Hanover Square, London, W. 1.

POWER-PLANT OF THE PANAMA CANAL.—Some particulars are given in *The Engineer* of the plant and machinery of the Panama Canal. The power required is obtained by utilising the flow of surplus water over the Gatun Dam, the height of which above sea-level enables an average effective head of 75 feet to be realised throughout the year. The power-plant at first installed comprised three turbines, each of a rated value of 2,250 kilowatts when running at 250 revolutions per minute and supplied with 500 cubic feet of water per second. A flow of 500 cusecs, with a fall of 75 feet, produces nominally 3,160 kilowatts, so that there is an efficiency margin of 37 per cent. The demand has been found to be much under-estimated, and it has become necessary not only to provide three additional machines of greater capacity, but also to increase the output of the existing generators. Of the three additional machines, only one is yet in position, but when the installation is complete there will be three units of 2,880 kilowatts each, and three units of 4,500 kilowatts each, totalling 22,140 kilowatts, and requiring a supply of just over 4,000 cubic feet of water per second. The electric energy is employed to drive the machinery of the locks at Gatun, Miraflores, and Pedro Miguel, of the haulage locomotives, of the permanent machine-shops, of the dry dock, and of the coal-handling plant, besides lighting the locks, and many towns comprised within the canal zone.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JANUARY 12...Brewing, Institute of (London Section), Imperial Hotel, Russell-square, W.C., 8 p.m. Mr. F. Ayton, "Electric Traction for Brewers."

Surveyors' Institution, 12, Great George-street, S.W., 8 p.m. Messrs. E. M. Konstam and C. H. J. Clayton, "Land Drainage from the Administrative and Engineering Point of View."

Geographical Society, Kensington-gore, W., 5 p.m. Captain H. Thomas, "Geographical Reconnaissance by Aeroplane Photography."

TUESDAY, JANUARY 13...Electrical Engineers, Institution of (North Midland Section), Hotel Metropole, Leeds, 7 p.m. Messrs. A. G. Ellis and J. L. Thompson, "Large Power Transformers."

Royal Institution, Albemarle-street, W., 3 p.m. Sir John Cadman, "Modern Developments of the Miners' Safety Lamp."

Civil Engineers, Institution of, Great George-street, S.W., 5.30 p.m. 1. Mr. J. Mitchell, "Whitby Harbour Improvement." 2. Mr. R. F. Hindmarsh, "The Design of Harbours and Breakwaters with a View to the Reduction of Wave-action within them." 3. Mr. J. W. Sandeman, "Wave-action in Harbour Areas, with special reference to Works for Reducing it at Blyth and Whitby Harbours." 4. Mr. W. Simpson, "The Improvement of the Entrance to Sunderland Harbour, with Reference to the Reduction of Wave-action."

British Decorators, Institute of, Painters' Hall, Little Trinity-lane, E.C., 7.30 p.m. Mr. A. C. Bawtree, "Colour: its Fundamental Laws and Scientific Method of Recording."

Photographic Society, 35, Russell-square, W.C., 7 p.m. Major G. W. C. Kaye, "Some Aspects of Radiology."

Anthropological Institute, 50, Great Russell-street, W.C., 8.15 p.m. Dr. A. C. Haddon, "The Outrigger of Indonesian Canoes."

Colonial Institute, Central Hall, Westminster, S.W., 8 p.m.

Horticultural Society, Vincent-square, Westminster, S.W., 3 p.m.

WEDNESDAY, JANUARY 14..ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 3 p.m. (Juvenile Lecture.) Mr. L. Pendred, "Railways and Engines." (Lecture II.)

Electrical Engineers, Institution of (Wireless Section), at the Institution of Civil Engineers, Great George-street, S.W., 6 p.m. Captain R. J. Round, "Wireless Direction and Position Finding."

United Service Institution, Whitehall, S.W., 3 p.m. Major A. C. Smith, "The Traditions of the British Navy."

Literature, Royal Society of, 2, Bloomsbury-square, W.C., 5.15 p.m. Professor W. de la Mare, "Islands; and Robinson Crusoe."

Faraday Society, Royal Microscopical Society, Optical Society, and Photomicrographic Society, in co-operation with the Optical Committee of the British Science Guild, at the Royal Society, Burlington House, W., 4.30 and 8 p.m. "Symposium and General Discussion on the Microscope: its Design, Construction and Applications."

THURSDAY, JANUARY 15...Ice and Cold Storage Association, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5 p.m.

Linnean Society, Burlington House, W., 5 p.m. Dr. B. Daydon Jackson, "Methods of Botanic Illustration during Four Centuries."

Chemical Society, Burlington House, W., 8 p.m. 1. Messrs. L. E. Hinkel and H. W. Cremer, "The condensation of acetoacetic ester with p-dimethylaminobenzaldehyde and ammonia." 2. Messrs. G. S. Butler and H. B. Dunnicliff, "The action of alcohol on the sulphates of sodium." 3. Messrs. M. Nierenstein, C. W. Spiers, and in part the late K. C. R. Daniel, "Guarana Tannin." 4. (*a*) Mr. R. Lessing, "The behaviour of the constituents of banded bituminous coal on coking. Studies in the composition of coal"; (*b*) "The mineral constituents of banded bituminous coal. Studies in the composition of coal." 5. Messrs. P. Ray and P. V. Sarkar, "On the hydrazino-thio-cyanates of certain divalent metals."

Royal Institution, Albemarle-street, W., 3 p.m. Dr. R. R. Terry, "Renaissance Music in Italy and England." (Lecture I.)

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Mr. C. Marriott, "Review of Members' Exhibition of Photographs."

FRIDAY, JANUARY 16...Royal Institution, Albemarle-street, W., 9 p.m. Professor Sir James Dewar, "Low Temperature Studies."

University of London, University College, Gower-street, W.C., 5 p.m. Dr. T. Borenius, "Mediæval Art." (Lecture I.)

Civil Engineers, Institution of (Students' Meeting), Great George-street, S.W., 6 p.m. Mr. R. B. Dunwoody, "The Economic Requirements for Inland Navigation Transport in the British Isles."

SATURDAY, JANUARY 17...Royal Institution, Albemarle-street, W., 3 p.m. Mr. A. Noyes, "The Anglo-American Bond of Literature."

Municipal and County Engineers, Institution of (South-Western District), The Castle, Exeter, 2 p.m. Mr. W. P. Robinson, "A Few Notes on Road Maintenance, with particular Reference to Devonshire."

Journal of the Royal Society of Arts.

No. 3,504. VOL. LXVIII.

FRIDAY, JANUARY 16, 1920.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

MONDAY, JANUARY 19th, at 8 p.m. (Cantor Lecture.) CAPTAIN H. HAMSHAW THOMAS, M.B.E., M.A., F.G.S., Fellow of Downing College, Cambridge, and formerly of the Royal Air Force, "Aircraft Photography in War and Peace." (Lecture I.)

WEDNESDAY, JANUARY 21st, at 4.30 p.m. (Ordinary Meeting.) ALFRED H. POWELL, "Ancient Cottages and Modern Requirements." The Right Hon. EARL FERRERS will preside.

Further particulars of the Society's meetings will be found at the end of this number.

COUNCIL.

In consequence of his appointment as Permanent Under-Secretary of State for India, SIR WILLIAM DUKE, G.C.I.E., K.C.S.I., has been compelled to resign his positions as Vice-President of the Society and Chairman of the Indian Section Committee.

At their last meeting on Monday, the 12th inst., the Council elected SIR CHARLES STUART BAYLEY, G.C.I.E., K.C.S.I., to fill these offices.

JUVENILE LECTURE.

On Wednesday afternoon, January 14th, SIR HENRY TRUEMAN WOOD, Chairman of the Council, in the chair, Mr. LOUGHNAN PENDRED, M.I.Mech.E., Editor of *The Engineer*, delivered the second and final lecture of his course on "Railways and Engines."

The lecture opened with a description of a locomotive boiler. The boiler is the most important part of a locomotive, for a very bad engine could be driven by a very good boiler, but the best engine in the world would be useless with a bad boiler. The boiler has to be fed just as the body is fed, and the more the power that it is desired to get from a boiler the more coal it must be given to burn. The business of a boiler is to turn water into steam by boiling it. In a first-class boiler a quarter of a pound of coal will turn a quart of water into steam. A big locomotive pulling a heavy train needs about one ton of coal every hour, and the fireman has to throw the equivalent of 40 lb. of coal per minute into the fire-box.

The question of the pressure inside a boiler was then discussed, and it was pointed out that though 150 lb. per square inch did not seem much, it meant ten tons, or the equivalent of one hundred sacks of coal, on every square foot.

A sectional model of a North Eastern locomotive lent by Sir Vincent Raven was then completely explained.

A number of slides were then shown, a set of three illustrations showing the water pick-up for filling the tender of a moving train. Others exhibited early railway coaches, etc.

The lecturer then turned to the engine, and after explaining by the help of a rough model that an excentric is no more than a greatly enlarged crank-pin, he demonstrated the working of an engine by means of a sectional wooden model which was built up before the audience, each part being explained before being put in place. The model showed the action of a flat slide valve, reversing by means of a link, and the meaning of "notching up."

Signalling was then taken in hand, the block system being described by the parallel of a long passage with many doors of which no two adjacent ones could be opened at the same time. A pair of block instruments was then shown in action, and some of the details of signalling were explained by slides and models.

The lecture concluded with a description of a run on a locomotive foot-plate and instructions how to drive an engine. A picture of the cab of a modern L. & S.W. engine was used for the purpose, and it was pointed out that the driver and the fireman had no less than twenty-two separate levers, gauges, cocks, etc., to attend to during a run.

On the motion of the CHAIRMAN a vote of thanks was accorded to Mr. Pendred for his interesting course, and in replying Mr. Pendred said he would like to take the opportunity of thanking all the people who had helped him by the loan of models and slides. He would mention first Sir Vincent Raven of the North Eastern Railway; Mr. Bowen Cooke of the London and North Western, whose representative in London,

Mr. Meacock, had given every assistance; and Sir Henry Fowler of the Midland, who had sent locomotive models. The models lent by Sir Vincent and brought up to London by Mr. Grey were exceptionally beautiful specimens. Then he had to thank Messrs. Sykes and their representative, Mr. Lascelles, and Messrs. McKensie and Holland for models of signalling apparatus; the Publicity Managers of the London and South Western Railway, Great Northern Railway, and Great Western Railway, who had been of the greatest help in various ways; and Mr. W. Hooper—who had a splendid collection of locomotive slides—for the loan of several of them. Finally, he wanted especial thanks for his assistant, Mr. Wilfrid Lewis, whose help had been simply invaluable.

THE SOCIETY'S OFFICES IN 1765.

The Duke of Bedford has very kindly given to the Society an old plan of that part of the Bedford estate where the premises were situated which the Society occupied from 1759 to 1774, when they moved to their present house in the Adelphi. It is entitled "A Plan of Houses in the Strand and in Denmark Court proposed to be sold to His Grace the Duke of Bedford by Messrs. Couts Evans & Others. And of Houses and Ground thereunto adjoining—July 31st, 1765." The plan practically covers the same area between Southampton Street and Burleigh Street west and east, and the Strand and Tavistock Street south and north, as is shown in the illustration on page 56 of Sir H. T. Wood's "History of the Society." At the time this ground formed part of the Bedford Estate, but it was sold at a later date. The plan shows clearly marked out a space of ground as "in the occupation of the Society for Arts and Sciences." No details of the buildings are given, as the draughtsman was evidently concerned only to show the particular houses which were offered for sale, and were presumably afterwards bought. In fact he left the greater part of the centre of his plan blank, and utilised the space by inserting a schedule of the rentals of the houses in question.

The space allotted to the Society corresponds with that shown in the sketch in the History, and inasmuch as the details of this sketch were partly conjectural, as it was made up from various sources, the new information is valuable because it confirms the results of the previous inquiries. The only new detail given is that the frontage to the Strand is stated as 21 ft. All that was known before was that the Society had an entrance in the Strand, but the width of it was not known.

It is highly probable that this plan is the only one in existence showing the premises occupied by the Society from 1759 to 1774, the position of which had been forgotten, and was quite unknown until the investigation was made of which an account is given in the History.

PROCEEDINGS OF THE SOCIETY.

TRUEMAN WOOD LECTURE.*

Wednesday, April 30th, 1919; Mr. A. A. Campbell Swinton, F.R.S., M.Inst.C.E., M.I.E.E., Chairman of the Council, in the chair.

The Chairman, in opening the meeting, said the present was the second of a series of lectures that had been inaugurated in commemoration of Sir Henry Trueman Wood's long services as Secretary of the Society. At the beginning of the war, in 1914, the country found itself in a very awkward position with regard to glass of all descriptions, both for the chemical trades and for optical and other purposes, by reason of the fact that this country had got into the habit of importing practically all the glass it required from Germany, Austria, and other foreign countries. As a result, there was a great shortage of glass soon after the outbreak of war, which threatened a very serious condition of affairs, because glass was required for many instruments and apparatus necessary for the carrying on of the war. Sir Herbert Jackson was asked by the Government to look into the matter, and as a result of his experiments the country was in a very short time enabled to produce glass of the different descriptions that were necessary. It was a really wonderful piece of work done in a very short space of time, and as the subject of the lecture was "Glass and Some of its Problems" he had no doubt that it would be well worth listening to.

The lecture delivered was—

GLASS AND SOME OF ITS PROBLEMS.

By Sir Herbert Jackson, K.B.E., F.R.S.

Before I begin the lecture, I should like to say how much I appreciate the privilege of being asked to give this, the second Trueman Wood Lecture. Our Chairman has stated the origin of these lectures, namely, to keep alive the memory of the long and distinguished work of Sir Henry Trueman Wood in promoting and increasing our knowledge of the arts and sciences in the best interests alike of this Society and of the nation. I am sure I express the feelings of everybody present when I say how delighted we are that he is here to-day, and when I express the hope that he may be able to attend many more lectures to be given in his honour.

It was suggested to me that this lecture should have something to do with glass, and it was hoped that there might be experiments. The production of glass is difficult to illustrate efficiently in the course of a lecture. It will, therefore, only be dealt with very briefly and

* Owing to extreme pressure of work, Sir Herbert Jackson has only recently been able to complete the MS. of his lecture. This accounts for the delay in its publication.

generally before turning to some of the problems connected with glass which I hope to make the chief part of this lecture. The Chairman, in his opening remarks, has spoken of the many varieties of glass. We hear of optical glass, window glass, table glass, industrial and scientific glass, opal glass, coloured glass, etc., all of which have many properties in common while exhibiting differences which depend chiefly upon the materials used in making them, the various proportions in which the materials are used and, to some extent also, on the methods of manufacture. It will be convenient to take window glass as one of the simplest of glasses, and briefly to consider its composition. The essential materials required are sand, chalk, and sodium carbonate. When these are heated together in suitable proportions there results a glass containing silica, or the oxide of the non-metal silicon, lime, or the oxide of the metal calcium, and soda, or the oxide of the metal sodium, combined together to form what is generally spoken of as a soda lime silicate. Of these ingredients the silica is the acid constituent, and the lime and soda are the basic constituents of the glass. Most glasses are composed of acids as oxides of non-metals, and bases as oxides of metals combined together. The chief acid ingredients to be found in various glasses are silica, boron trioxide, arsenic trioxide, and pentoxide, phosphorus pentoxide, tin oxide, and antimony pentoxide. The chief bases are the oxides of potassium, sodium, lithium, barium, calcium, magnesium, zinc and lead. Aluminium oxide, a constituent of several glasses may, in some, play an acid part and in others may act as a base. With certain reservations, this may be said also of antimony trioxide. The list is not exhaustive, but is sufficient to indicate that a number of glasses is possible from various combinations of these acids and bases. (The materials used for producing opals and coloured glasses will be referred to later.) The number of glasses made is very large, and it would take at least all the time at my disposal to describe in any adequate manner how they differ from one another in composition and in those properties which make each one suitable for the purpose for which it was devised. It may, however, be appropriate here to mention that in the great variety of optical glasses, there are many which do not differ materially in composition from glasses used for other purposes. For example, a good window glass could be made with pure materials and stirred in the process of its manufacture, so as to secure such a clear and homogeneous product as would serve as one type of optical glass. The chief general properties which are desirable in all optical glasses are identity of composition throughout the whole mass of the glass, great clearness and transparency for all the colours of the spectrum, freedom from strain arising through imperfect annealing, and durability under ordinary exposure to the atmosphere. It will be seen, therefore, that apart from considerations of special optical properties, I refer to the refractive indices and dispersive powers of various optical glasses, the main difference between them and other glasses is that the highest art of the glass manufacture is called for in their production, and great care is needed to ensure purity of the materials used and accuracy of proportions, so as not only to be able to produce glass of the optical properties required, but to reproduce it with the closest possible identity of composition. With these very brief remarks on glass generally, we may turn now to some of the problems which I thought might be interesting to consider, and the first one is how far can glass be called a solid?

A solid is defined in a dictionary as having a fixed form, and being in a state in which the component parts do not tend to move freely among themselves. With regard to glass, we may ask for how long is it fixed in form, and what are the limitations of freedom of movement which we ought to consider? It is a common experience that long straight pieces of glass rod or tubing, left supported so that their own weight tends to bend them, will bend in the course of time, and in some years will become definitely bowed. Varieties of glasses differ in the readiness with which they show this flow under stress; but not any glass is so perfectly solid as to give no indication of movement under stress if tested by sufficiently delicate means. This question of permanent stability of form in glasses has some bearing on the choice of glass for the manufacture of large lenses and prisms, and the flowing of the surface of glass under mechanical pressure comes in as a very important matter in the explanation of the mechanism of polishing glass surfaces. A great deal has already been written on this subject, and it would take too long to deal with it here. Another reason why I refer to it but intend to leave it is that I hope it will not be long before the published papers and other work of Sir George Beilby, on the influence of mechanical disturbance on the physical state of a very large number of substances, will be brought together into one connected story,

when it will be seen that this subject of polishing glass has been dealt with in a comprehensive manner, and that the principles underlying it are shown to have very wide application.

The question of the relative plasticity of various glasses has two important bearings which are of some interest. For many industrial and scientific purposes it is necessary to be able to seal metallic wires into glass, and early in the war some difficulties were experienced in obtaining suitable glasses. To obtain successful joints between the metal and glass without fear of the latter cracking, it was generally considered that the glass aimed at should be one which had a coefficient of expansion as close as possible to that of the metal intended to be used, and there is no doubt that this question of expansion has to be taken into account. In making a large number of glasses and in experimenting with them there did not appear to be that close connection between the coefficient of expansion of the glass and its behaviour with metal wires which was at first expected. The coefficient of expansion of copper is about double that of platinum, and the coefficient of iron is about midway between the two. Glasses were made which gave successful joints with platinum and copper wires, but which cracked inevitably with iron wire. It did not appear, therefore, that the coefficient of expansion was the only factor to be taken into consideration. It is an important factor, but not the only one, and it soon became clear from the study of various glasses that the plasticity of the glass had a great deal to do with its utility. A careful examination showed that there was evidence that in the case of soft metals, like copper and platinum, the glass in setting could pull and deform the metal wires so that no great strain was permanently left in the glass. With hard metals like iron and tungsten, it was necessary to devise a glass which had marked plasticity over such a long range of temperature that when the glass and metal joint cooled, the glass would flow and follow the contraction of the metal and so the stress would, to some extent, be relieved. And this is an example of the need of asking the question: Is glass truly a solid, and how far can a glass be made which will flow, very much less, of course, than pitch, but in an analogous manner? The other bearing of the question is on the cracking of glass vessels with rapid changes of temperature. It is clear that if the strain set up by such changes can be quickly and readily released, the danger of cracking will be very small. The coefficient of expansion is, of course, a very important factor in this respect. It is well known that vitreous silica vessels can be heated to redness and plunged into cold water without cracking, and this is, no doubt, correctly considered to be due almost entirely to the low coefficient of expansion of silica. In the case of glasses also, the lower the coefficient of expansion of a glass the better will that glass stand rapid changes of temperature; but it is possible to make glasses approximately with the same coefficient of expansion and to find one—and that, perhaps, the one with a slightly higher coefficient of expansion—which will not crack under conditions in which the other cracks readily, and a study of the two glasses shows that the more stable one is the more plastic. On the whole, perhaps, it is not too much to say that glass may be looked upon as an extremely viscous liquid so slow in its movements in some types of glass that ages might elapse before any marked change in form could be observed under a strain just short of a breaking one for the glass, while in others it is possible to show that the glass does flow, even at the ordinary temperature, to a small extent in a relatively short time.

The next problem to be considered may be also put in the form of the question: Is glass truly amorphous or vitreous or has it any crystalline structure or tendency to crystalline structure? There are many substances which can be obtained in the vitreous state and also in the crystalline state, and which can be changed from one to the other. As one example, arsenic trioxide may be mentioned. It can be produced as a clear transparent glass which slowly changes at the ordinary temperature into an opaque white substance resembling porcelain in appearance. The opaque white substance is crystalline. It is the crystalline variety into which the vitreous will be slowly but completely changed. Again, if sulphur near its boiling-point be poured in a thin stream into cold water, it sets as plastic threads, and for our purposes we may speak of this as the vitreous form of sulphur; left at the ordinary temperature, it slowly changes into the crystalline form.

Two other examples may be given which, in a way, are perhaps more closely analogous with glass, since they are solutions of substances, and not merely single substances as in the previous illustrations. Solutions of sodium acetate and Rochelle salt, obtained by adding to hot water as much of the salts as will dissolve and cooled so that no unfiltered air can enter the containing vessels, and carry nuclei to start crystallisation, remain clear and fluid at the ordinary tempera-

ture. If such a "supersaturated" solution of sodium acetate be cooled in liquid air it is converted into a vitreous solid quite clear and transparent. On removal from the liquid air its temperature rises and very soon crystallisation starts and proceeds right through the vitreous mass. The solution of Rochelle salt treated in the same way yields a similar vitreous mass, but as it warms up no crystallisation takes place. It slowly goes back to the original liquid condition. The cold vitreous sodium acetate solution may be taken as analogous to a glass from which crystals readily separate on warming up, while the Rochelle salt is analogous to a glass which shows no tendency to crystallise through the whole range of temperature from the solid form to the point at which it is a mobile liquid. Glasses are known which tend to crystallise in all degrees of readiness. As a simple glassy substance, zinc silicate may be taken. It can be obtained, by moderately quick cooling of the molten mass, in a vitreous form which is stable for a number of years—at least, some has remained with no sign of crystallisation at the ordinary temperature for twenty-two years. By heating to a few degrees above its softening point, it changes to a translucent crystalline mass. Taking a more complex glass, but still a moderately simple one, we may study the behaviour of heat on a lime soda silicate glass. The specimen of greenish glass with some large and many smaller opaque nodules in it was given to me in the early part of the war by Mr. Frank Wood as an example of glass taken out of a tank furnace. The nodules are calcium silicate, which is the least fusible silicate potential in the glass. They have been formed through the glass in the particular part of the furnace from which it was taken being at a temperature too low to keep this silicate in solution or combination, and it has separated out in the form shown. To get this glass back to a complete vitreous state again would require a somewhat higher temperature than is used in the manufacture of the glass, since the calcium silicate is itself very infusible, and the rest of the glass has to be made very fluid before such masses of this silicate can be dissolved in any reasonable time.

This glass then, in a molten state, is an example of a solution out of which a slightly soluble constituent has separated, when the conditions were suitable for that separation. It may be interesting to turn for a moment to a consideration of conditions for crystallisation, and to go back to simple glassy bodies such as zinc silicate and some borates. With all the vitreous substances which have been tried and have been made to crystallise, there is a certain temperature at which crystallisation proceeds readily, and for small ranges above or below that temperature no crystallisation occurs. Associated with alteration of temperature, there is change in the viscosity of the vitreous substances, and hence in the freedom of movement of their particles among one another. The effect of this can be well seen when a crucible full of molten zinc silicate is removed from the furnace. If the mass be small so that cooling is quick, it remains a glass and has to be re-heated before crystallisation occurs. With a larger quantity and consequently slower cooling, the mass may become wholly crystalline, or only partly so if some of the vitreous form reaches a temperature at which its viscosity is too great, and freedom of movement of its particles too small for rearrangement into crystals to take place. Some borates are very convenient for illustrating the change from the vitreous to the crystalline state. Boric anhydride itself has not been made to crystallise, and as might be expected, the greater the proportion of it in a borate, the less marked is the tendency of a fused mass of that borate to crystallise on cooling. Of the three borates, $CaO.2B_2O_3$, $CaO.B_2O_3$ and $2CaO.B_2O_3$, the first can be obtained vitreous by fairly quick cooling, and pieces of it can, with care, be heated again to remove the strain produced, that is to say, it can be annealed. The second crystallises from fusion much more readily, cooling has to be quicker to keep it in the vitreous state, and only small glassy pieces can be obtained, which crystallise, however, on attempting to anneal them. The third borate can only be kept vitreous in very small globules.

Statements, however, of the bulk which can be obtained of any readily crystallisable vitreous body require a certain reservation. It is well known that crystallisable bodies in the fluid state may be cooled considerably below the temperature at which they would ordinarily solidify to a crystalline mass, if they are freed from all foreign material. Water is a well known example, and among many others which could be cited, mention may be made of salol (phenyl salicylate). It melts at 43° C., and if the crystallisation of a film of the molten liquid be watched under the microscope, numerous small bubbles of gas can be seen to form during crystallisation. The gas appears to be modified air. If salol be melted, allowed to solidify and re-melted in vacuo, so as to remove all this gas, and the process repeated several

times, it is found that the molten salol must be cooled many degrees (fifty or more) below its melting-point before crystallisation takes place. A small crystal of salol will start it, unless, as can be done on small quantities, cooling has been carried far enough to increase the viscosity of the fluid to such an extent that the particles have not the freedom of movement necessary for the change to the crystalline form. So it is also with a great number of glassy bodies, and the bulk which will retain the vitreous form can be largely increased since by fusion and crystallisation several times they solidify at progressively lower temperatures, until the time comes when they get quite cold in the vitreous state. For instance, the amount of vitreous zinc silicate obtained has been raised from twenty grams at one heating up to a kilogram by five fusions. The calcium borate $2CaO.B_2O_3$ has, after several fusions, been cooled to five hundred degrees below its ordinary solidifying point. When it does crystallise and the temperature rises the recalescence is remarkably bright. Long continued heating a few degrees above their solidifying points similarly retards the crystallisation of many vitreous bodies, but it is not so effective as the alternate fusion and solidification. One reason at least is not far to seek, if the two processes be tried so that gases evolved can be pumped off and their amounts measured. The process with alternations yields much more gas in any given time. With all the glasses, simple silicates and borates, which have been studied so far, the chief gas evolved has been found to be water vapour, and with the progressive removal of it the vitreous state has been found to persist more and more. Direct introduction of water subsequently has been found to promote ready crystallisation.

In connection with the comparison of long continued heating of a melt with alternate fusion and solidification, one extreme instance is worth noting. For a special optical glass, rich in phosphoric anhydride, an experiment was tried with ammonium phosphate to find if this substance could be used in the batch mixture for the glass. A nice clear fluid melt was obtained, which was kept fluid for several hours after all traces of gas bubbles had gone. The melt was well stirred and cooled till it was quite viscous, when it was left to get cold slowly. The next morning the furnace top was found forced off, and resting on a spongy mass of about thirty times the volume of the original glass melt. The changes occurring when solidification was approaching, had evidently been accompanied by the evolution of a large volume of gas, no doubt most of it ammonia, since this substance was smelt on grinding the spongy mass up. The ground material was then fused and gave a stable glass.

Reverting to the question—Is glass truly vitreous, or is there evidence of any crystalline structure in it, and bearing in mind that glasses are known which exhibit all states of preparedness to yield crystals at some temperature or other, and that the tendency to the segregation of some ingredient of a glass is enhanced by the presence of small amounts of foreign substances and notably of water, one would rather expect to find a good many glasses in which some evidence could be discovered of the early stages of orderly arrangement of particles towards the crystalline form. So far, etching glass surfaces with hydrofluoric acid has failed to reveal any of the net-work of crystalline structure filled in with vitreous material which is sometimes described as representing the texture of glass. Tearing the surface of glass by letting a film of strong glue dry and contract on it is also stated to reveal a crystalline network. Both the etching and this method give markings, very like a network no doubt, but the figuring of the surface seems to be more correctly ascribable to surface tension. Nothing which could be called definite evidence of crystalline structure is visible with any kind of illumination under the microscope of such surfaces, but this is not to deny that the texture of some glasses may be that of a network of crystalline compounds enclosing vitreous bodies.

Certain facts, from which it appears reasonable to conclude that many glasses have something of a crystalline nature in them, have been obtained from a study of the phosphorescence of various glasses and other vitreous compounds exhibiting different degrees of readiness to pass into the crystalline state on heating. Much of the work was done about twenty years ago, but more recent experiments have not modified the conclusion then formed that a truly vitreous body exhibits no phosphorescence in ultra violet light or X-rays or under cathodic discharge. Nearly every glass shows some phosphorescence and some show it very strongly, as, for example, the glass from which X-ray bulbs are largely made, and which gives the well-known green glow when the tube is in use. If some of this glass be fused and very rapidly chilled, as for example, by making a Rupert's drop from it, the glass is practically non-phosphorescent so far as its surface is concerned. A very little distance below the surface the

chilling was not sudden enough to prevent some change of the truly vitreous to an attempt at crystalline structure, so that just below the surface, as shown by broken pieces of the drop, the glass exhibits phosphorescence. The tail of such a Rupert's drop, if heated below the temperature at which the thin thread of glass bends, is found to be strongly phosphorescent, and the glow under cathode discharge can be seen to fade slowly away towards the part which was not heated. Many observations with vitreous borates and silicates have shown similar phosphorescence, appearing more and more strongly as the vitreous bodies are made to approach the crystallising stage. There does seem, therefore, reason to state that, given a body which in its crystalline state exhibits phosphorescence, it will not do so when it is in a truly vitreous state, and to infer that if a glass be phosphorescent there is something of a crystalline nature in it. It would not be right to come to the conclusion that a glass showing no phosphorescence is free from anything crystalline, since there may be crystalline structure in it which is not in the sensitive state to be revealed by phosphorescence. It would take up too much time to elaborate this further; but generally it may be said that a number of experiments on glasses, borates, etc., go to show that in some non-phosphorescent glasses there is most likely some crystalline formation, since the introduction of minute amounts of certain bodies not usually present in these glasses, as manufactured, will render them quite markedly phosphorescent; and again, the surfaces of Rupert's drops made from these sensitive glasses show no phosphorescence. Before going on to deal shortly with some points about devitrification, I may point out that boric anhydride, which has a marked effect in preventing crystallisation in glasses and in enhancing the stability of the vitreous form, is a fatal ingredient to add to a Uranium glass if strong fluorescence in ultra violet light be aimed at.

It may be concluded from what has been said or suggested that the question whether glass is crystalline or not has a bearing on the problem of devising, manufacturing and annealing optical glasses. It has, perhaps, a more obvious bearing on the problem of producing glasses capable of being freely worked in a furnace or in the flame of a blowpipe. To the flame worker especially, a glass prone to devitrification is a source of trouble. It would take at least a whole lecture to deal adequately with all the changes noticed in the numerous types of glasses which have been studied for their behaviour in the flame. I will confine myself merely to mentioning that the segregation of less fusible vitreous bodies giving a kind of crinkled skin to the glass, separation of amorphous silicates, the formation of very minute bubbles giving a grey look to the glass, as well as true crystallisation, are all frequently referred to as devitrification. It is mainly about the last form of it that there is time in this lecture for a few remarks.

There is great variety in the behaviour of glasses in a flame. A soda-lime silicate can be made which is hardly workable at all in the flame, it devitrifies so soon; but the same glass may be worked, if heated by radiation—for instance, in a muffle furnace. At the same time, it must be understood that exposure in the muffle may bring about devitrification even quickly, if the temperature is such as to bring the glass to the right state of fluidity for re-arrangement of some of its particles in the crystalline form. It would appear, therefore, that the difference between the behaviour of the glass heated in the flame, and heated by radiation, may be explained by the difference in temperature reached by the glass in each case, and no doubt this is a most important part of the explanation. Recalling what was said, however, about the conditions for crystallisation of vitreous bodies, there is, apart from temperature, the question of purity to be taken into account. The problem is whether the readier devitrification of a glass in the flame can be ascribed solely to the surface of the glass being exposed to a very high temperature, and so for a thin layer reaching the right state of fluidity for crystallisation, or whether chemical action also plays a part, *i.e.* whether the hot gases of the flame act on the glass and assist the segregation of parts of it by disturbing the chemical equilibrium of the bases and acids of the glass. Attempts to get an exact reproduction of the behaviour of a glass in a flame by exposure of thin pieces of the same glass to intense heat by radiation, have given results showing close similarity in some glasses and great differences in others. It would be somewhat out of place, and certainly tedious in a lecture such as this, to go into the details which seem to justify the statement that a survey of the relative behaviours of a very large number of different types of glasses exposed to flames or to heat by radiation, and chemical examination of the products, leads to the conclusion that water, and to a smaller extent carbon dioxide, do act

chemically when many glasses are heated in flames, and that this action plays an important part in the initial stages at least of devitrification. As the most simple example, which I can choose, of marked difference in composition of a glassy body heated by radiation, or in a blowpipe flame, ordinary borax, $Na_2O.2B_2O_3$, may be taken. Heated in a muffle up to about 1450° C. until much of it has volatilised, the residue may, according to the time of heating and the temperature, have a composition represented by anything between $Na_2O.8B_2O_3$ to $Na_2O.15B_2O_3$; but it has not been found possible, under any conditions, in a blowpipe flame, to get a residue from borax with the proportion of boric anhydride greater than is represented by about $Na_2O.3B_2O_3$. It is difficult to ascribe this difference solely to the effect of different temperatures. With some glasses, however, there is visible evidence of the disturbing influence of the hot gases of the flame. A glass containing barium oxide, which was heated and re-heated many times by radiation of varying intensity, and which was most reluctant to show any signs of crystallisation, became in the blowpipe flame, or in a hydrogen flame, grey at once over its surface, and soon afterwards signs of crystallisation were readily noticeable. The initial grey effect was seen under the microscope to be due to numerous very minute bubbles caused apparently by the rapid absorption and subsequent evolution of gases. As the question considered here is the influence of the hot gases of a flame to hasten devitrification, there is no occasion to discuss the well-known effect of an ordinary blowpipe flame to blacken glasses containing lead or similarly reducible metals, except to say that experiments show that in many instances the process of alternate reduction and oxidation which sometimes occurs when such glasses are being worked in the flame, does also appear to hasten devitrification.

Mention was made above of the influence of boric anhydride to retard the crystallisation of glasses in which it is an ingredient. Alumina is another substance the presence of which confers upon a glass the property of working well in the flame without devitrification. More striking, perhaps, as a vitrifying agent is titanic oxide. A soda-lime silicate glass was made which could not be worked in a flame at all so readily did it devitrify. The substitution of a small amount of its silica by titanic oxide converted the glass into one which could be heated and worked in the flame almost indefinitely without visible change. The statement "without visible change" is true of the behaviour of this glass; but some, and notably very soft glasses containing titanic oxide, become coloured in the ordinary blowpipe flame through reduction of this oxide to a lower state of oxidation. Zirconium, tin and thorium oxides, have been found to promote the stability of the vitreous state in a number of glasses prone to devitrification in the flame. They are mentioned as being of the same chemical family as silica and titanic oxide; but to deal with the effect of a number of rarer compounds not generally employed in glass-making would take up too much of the rest of the time at my disposal. Arsenic and antimony oxides may also be put among substances which render glasses less liable to devitrification; but glasses containing these oxides are not suitable for ordinary working in the blowpipe, since they darken in the reducing area of the flame. Tin oxide, mentioned above, is also not a generally suitable ingredient, since some glasses containing it darken badly through reduction in the flame, though others can be made which are quite workable except in the hottest kind of blowpipe flame.

I must leave out of consideration the relation of general composition and of varying proportions of ingredients to the tendency of glasses to devitrify, and content myself with the remark that for glasses of comparable composition those containing soda only as the alkali are usually found to devitrify more readily in the flame than those in which the alkali is potash, or a good proportion of potash with soda.

In this lecture it will only be possible to deal more or less briefly with opal and coloured glasses. Many vitreous bodies which crystallise fairly readily when heated can be seen to pass through a stage in which the material segregating from them appears first as an opalescence increasing in density as the heating is continued and finally passing into a visibly crystalline form. A glass approximating in composition to $Na_2O.CaO.8SiO_2$ shows this opalescence well before small crystalline nodules appear similar to those in the tank glass referred to earlier. Various silicates and borates of calcium, barium and magnesium show the same kind of phenomenon more readily and, by quickly cooling when a stage of dense opal appearance is reached, sections (or, what is just as good for the purpose, the finely ground glassy material mounted in Canada balsam) can be examined under the microscope and the opal effect shown to be due to the scattering of light by numerous small

transparent globules. Any glass from which, on cooling, part of it segregates out in very small particles evenly diffused through the mass, may be called an opal glass whether the fine particles are crystalline or amorphous, but the usual opals owe their milkiness to globules, in which no evidence at least of the crystalline state can be found. Under the microscope the globules, if sufficiently visible as distinct particles, appear vitreous and transparent, just as in milk the fat globules are seen to be themselves colourless and transparent. Among the many substances which can be used to produce opal glasses, the most common are fluorides such as calcium fluoride, cryolite the double fluoride of sodium and aluminium, and calcium or sodium phosphate, less commonly the arsenates of these metals. These substances can be included in the batch mixtures of ordinary soda or potash lime glasses, or lead glasses or zinc glasses. In the making, opal glasses are usually clear at a high temperature and "strike" opal on cooling. To what extent the glass has to be cooled before becoming opal depends on the concentration of the particular opal-producing compound which is held in solution in the very hot glass. Opal glasses produced with phosphates "strike" generally speaking at higher temperatures than those made with fluorides, the compounds formed in the glass by the latter being more soluble than those due to phosphates, at least in the case of most opal glasses made on a commercial scale. Whatever opal-forming material is potential in the molten glass, if its concentration be great, the glass "strikes" opal quickly and with relatively little cooling and becomes a denser opal as cooling proceeds, until the stage is reached when no more material segregates. Just, however, as in the crystallisation of an ingredient in a glass, cooling may occur so quickly that a state of viscosity is reached in which crystallisation cannot proceed, so with opal glasses the concentration of the opal-producing material may be such that only a little of it comes out of solution before the viscosity of the glass gets too great to allow of further separation. With still less concentration, moderate-sized pieces of the glass may even solidify in a perfectly clear condition, but again, just as re-heating will often cause a glass which has cooled vitreous to become more or less crystalline, so re-heating the intended opal glass will cause it to "strike." This can be illustrated by blowing a bulb from a tube of an opal glass. If the bulb be not too thick, and the concentration of the opal-forming material be not too great, the glass will go quite clear in the flame and the blown bulb will remain quite clear on cooling. If the bulb be then again heated gradually in a flame, the whole process from a mere trace of opalescence to a very dense opal can be watched. If during the various stages of opacity the light transmitted through the glass be observed, it will be seen to change from light orange yellow to darker and darker orange and orange red, until no more evidence of colour is seen, but only a general translucence. If thin sections (or ground-up pieces mounted in Canada balsam) of the opal glass in the various stages be examined under the microscope no separate particles in the earlier stages will be seen, even with lenses of large angular aperture, though their existence can be inferred from the opalescence which is to be well seen under the microscope with suitable black ground illumination. In the later stages of denser opal, separate particles are visible, and are seen to be progressively larger as the density of the opal is greater and greater.

When an opal glass is required for articles, the making of which involves working the glass in a muffle or in the flame, it is important that the separated globules shall not tend to aggregate or to pass into the crystalline state, otherwise the glass is found to have a rough surface. To guard against this, too great concentration of the opal-forming material must be avoided, and some workers prefer a glass which does not reach its full opal until it has been in the annealing oven. As a general experience with a wide range of all kinds of opals, it would appear that fluoride opals are more kindly in working than phosphate opals. This is more especially true for the denser kinds of opal. For merely opalescent glasses, phosphates give quite good results, but with greater concentration of the opal-forming substance there is a tendency towards crystallisation, which is more marked as a rule in the phosphate than in the fluoride opals. A dense opal suitable for working in a flame should "strike" opal even in thin pieces on removal from the flame, and should stand long-continued heating without losing its fine polished surface. When such a glass while opal is drawn out into a rod and longitudinal sections of the rod are examined under the microscope, the globules are to be seen egg-shaped or even elongated into minute rods. If an end of the opal rod be heated again to softening point and sections of that end be

examined, the opal-forming material is seen to have gone back to spheres, showing that even when separated out the opal material has about the same softening point as the rest of the glass. It is easily to be understood that if it has not, and the globules are of appreciable size, a glass containing them cannot be worked without roughening. One more point may be mentioned before concluding this short general account of opals. A glass may be required which, while remaining clear in thin pieces after removal from the flame, will "strike" on re-heating so readily that the temperature needed to develop the full density of the opal is not high enough appreciably to soften the glass and so cause deformation. One way of securing this behaviour is to add as an ingredient a small amount of a substance which will produce a trace of a compound insoluble in the glass except at very high temperatures. In the flame this compound persists as a slight turbidity and appears to facilitate the "striking" by affording nuclei on which the opal material can collect.

Coloured glasses are sometimes divided into two main groups: (*a*) Those in which the colouring matter is diffused in very small particles throughout the glass, and which may be likened to colloidal solutions; and (*b*) those in which the colouring substances are in a state resembling that of solution, and which may be likened more nearly to aqueous solutions of coloured salts. Just, however, as in aqueous solutions there may be traced or inferred all grades of subdivision of the colouring matter from separate particles which can be revealed by their scattering action on light, and which may be seen in the ultra microscope, through smaller and smaller particles scattering light less and less obviously down to those in the extreme state of subdivision frequently described as that of true solution, so in glasses similar grades of subdivision of their colouring matter may be seen or inferred.

It is in fact, impossible sharply to divide coloured glasses into these two groups; but it can be said of certain glasses that they are typical of group (*a*), and among the more common of these may be mentioned those owing their colours to the presence of gold, copper, and selenium. It is generally considered that these colouring agents exist in the glasses as metallic gold, metallic copper and elementary selenium respectively, and the varying colours which can be obtained in each case appear to depend on the state of division of the colouring agents, or at least to be associated with it. How far there is evidence that selective absorption of light has also to be taken into account, is a question which can hardly be dealt with in a short time.

With gold the colours most readily obtainable range from red to blue, through varying stages of purples. With copper in the metallic state the common colour is red; but it is possible to get variations very similar to those seen in gold glass, and a copper glass giving a definite blue by transmitted light has been obtained. It is to be understood that this blue was not due to copper in an oxidised condition, but to metallic copper. Selenium glasses are also generally red, but again states of division of this material can be secured which give other colours, although it is difficult, except on a very small scale, to obtain other than greys or neutral tints. With each of the glasses, in which gold, or copper, or selenium is present, quick chilling of the molten glass will, as in the case of opal glasses, yield a clear and colourless glass, and the greater the concentration of the colouring agents, the more sudden must the chilling be to secure this result. On re-heating these colourless glasses they, like the opals, "strike" and yield the colours which could have been obtained by slower cooling of the molten glasses. It may be of interest to deal with a gold glass a little more in detail. It is not easy to get a strongly coloured glass with gold added, in the form of gold chloride, to the batch mixture of an ordinary soda lime glass. Among the substances which enable one to prevent gold separating from the molten glass in the ordinary metallic state, the commonest used are the oxides of lead, tin and antimony. Bismuth oxide acts similarly, and so also does uranyl oxide. There are physical and chemical problems of much interest involved in this behaviour of these oxides; but it would lead us too far into technical details to attempt their discussion here. A gold glass containing oxide of tin may be chosen, because it can be made so that its behaviour can be studied either in the furnace or in a blowpipe flame. With a suitable concentration of the gold, and very slow cooling of the melt, all the ranges from red by transmitted light to a pale blue can be observed, and if rods are drawn out from the pot at intervals, and examined in a beam of light, it will be seen that, starting from a fine deep red by transmitted light, through the various stages of reddish and blueish purple and blue to the pale blue, there is progressively more and more marked scattering of the light, and the rods look more and more of an opaque

brown colour by reflected light, until in the later stages the appearance of precipitated gold is so marked as to leave no doubt that what has occurred has been a progressive aggregation of the gold into larger and larger particles. Microscopical examination of the glass at the different stages, gives clear confirmation of this and of the great similarity in the manner of separation of the gold to that of the materials which give opal glasses. Remarks made under opals and crystallisation of glasses about the influence of changing viscosities apply also, in a general way, to gold glass. There is one point in this connection which is worth referring to. If the suddenly chilled and colourless glass be returned, in small pieces at a time, to a pot in a furnace at a high temperature, about 1400° C., the glass can be melted and the gold still retained in it without appreciable loss by separation into the ordinary metallic state; but if it be slowly heated up it passes through the stages of colour previously described and, after complete fusion at a high temperature, practically all the gold will be found in a button at the bottom of the pot. Now, except in the case of a very soft gold glass, heating and working the colourless glass in the flame will only give a red glass, and no passage through the other stages is seen, or, in general, if the glass at any of the stages of colour be worked in the flame, the change of colour is but slight. The explanation seems to be that, throughout the mass of the glass the temperature never reaches high enough to give the state of viscosity for free aggregation of the gold particles, while, on the immediate surface of the glass the temperature may be so high that the gold is retained in solution, as it is in the highly heated furnace. It is very difficult to get a gold glass to behave like some opal glasses, in the sense that it will go clear and colourless in the flame and remain so when quickly cooled; but a copper glass can be made, in a similar manner with tin oxide, which will go quite colourless in the flame. Bulbs can be blown from it which remain white on cooling, and the gradual "striking" of a deep red colour observed on gently re-heating in the flame. It has been noticed in experiments with some copper glasses that, in the initial stages of "striking," the colour which develops is not red, but a dark neutral tint with a suggestion of olive green in it. This may be from copper in the very finest state of division in which it can exert visible action on light, or it may be due to the presence of traces of oxidised copper in the glass giving rise to the well-known dark compounds of cuprous and cupric copper. Certainly very dark glasses of rather similar tint can be obtained by intentionally allowing some oxidation to take place in the making of a red copper glass, or by fusing together a reduced copper glass with one in which the copper is fully oxidised. At the same time it is worth noting, and is perhaps suggestive, that a chilled and colourless gold glass which goes through the stages of very pale red to a fine full red on heating in the flame has, after six months' exposure to the β rays of radium, only developed a dusky neutral tint. A piece of glass of the same composition, except that there was no gold at all in it, has not been affected by the radium. It would lead too much into theoretical discussion to consider in what form gold, copper, and selenium exist in the respective chilled and colourless glasses, and how far they may be looked upon as being in combination, or merely in so fine a state of division that they have no visible effect on light. The chemical and physical evidence that, when they do give colour, they are in the elementary state, seems to be fairly conclusive; but this does not necessarily exclude the possibility of their being in something very like chemical combination in their colourless states.

Perhaps it is needlessly striving after definiteness to attempt to distinguish between bodies being dispersed in an extremely fine state of division, partly at least through chemical attraction for their solvent, and being held in a loose kind of chemical combination. Some consideration of such a question, however, is helpful in suggesting experiments, and some instances may be given. One is in connection with the composition of a glass to give the full possible colour with copper. The notion of something like chemical combination of the copper leads to the study of the effect of varying the relative amounts of the basic and acid ingredients of the glass. More of the basic part, such as the alkalies, might be expected to turn the copper out of combination, and more of the acid part to keep it in. It would be tedious to describe in detail the results of numerous trials with glasses, and the point can be equally well illustrated by simple experiments with borax beads. Copper oxide mixed with about twice its weight of tin oxide, can be dissolved in molten borax in an oxidising flame, and then reduced in a reducing flame. On cooling, the bead is either colourless or "strikes" red according to the concentration of the copper. If colourless it can, with suitable

concentration, be made to "strike by re-heating. Now, if to the bead which "struck" red on cooling, more boric anhydride be added, and the bead again fused, it will remain colourless on cooling; but, unless too much boric anhydride has been added, it will "strike" red on re-heating. Addition now of more alkali, in the form of sodium carbonate, will restore the property of striking red at once on cooling. Similarly it follows that a bead which remains colourless on cooling, but "strikes" on re-heating, can be prevented from giving any colour of copper at all by more boric anhydride, and the property of "striking" red on re-heating can be restored by the further addition of alkali. Of course, in making these various additions of alkali and acid to the bead, there must be a change in the concentration of the copper; but a bead can be got in so sensitive a condition that a mere trace of alkali will determine whether a red colour is developed or not, and a number of experiments on glasses and glazes do confirm the notion of chemical action playing a part on lines which would be expected from general chemical experience.

When manganese dioxide is added to a glass as a so-called decolourising agent, it is intended to be left in an oxidised condition, so as to give a violet colour which will disguise the green colour due to iron, and produce only a slight darkening of a neutral tint, scarcely visible except in thick pieces of the glass. Sometimes the violet tint is overdone, and can easily be seen and sometimes so much of the manganese dioxide has been reduced that the green due to iron is fully visible, the lower oxide of manganese giving no colour to the glass. In many instances of glasses in which one would be inclined, from mere inspection, to say that all the manganese dioxide has been reduced in the furnace, it has been found that a strong violet colour can be developed by exposure to radium or by cathode discharge in vacuum tubes. In parenthesis it may be remarked that potash glasses generally give a good violet and soda glasses a brown, or a brownish violet. Using small amounts of manganese dioxide in batch mixtures, as free as possible from iron, it has been found possible to get glasses practically colourless to the eye, some of which readily give colour on exposure to radium for a period during which others develop no colour. In making the latter, the conditions in the furnace were arranged for complete reduction of the manganese dioxide. In making the former, as little de-oxidation as possible was aimed at. In one instance, thin rods drawn from the melt of one of these, in which very little manganese dioxide was used, cooled almost colourless, but "struck" quite a marked violet colour on re-heating. This chilled glass was also very sensitive to radium. More urgent work prevented further experiments, but the facts so far obtained are mentioned as relevant to the question of the chemical condition of colouring agents in glasses, and as an illustration of one which would appear to be somewhat of a border line example of the groups (*a*) and (*b*) referred to previously. I am reluctant to dismiss the matter in this rather summary fashion, but the interesting speculations which will occur to many can hardly be dealt with shortly. I would, however, recall the well-known pink or violet colour to be seen in some window glasses which have been exposed for years to daylight. In all examples which I have been able to examine, manganese has been found to be present, and I can imagine that the colour has developed in daylight in a manner similar to that in which it has been found to be developable in manganese glasses by radium, by cathode discharge, or by heat. The colour of the old window glasses is a little puzzling, if they are soda-lime glasses One would expect them to be browner in tint; but perhaps on insufficient grounds, since no direct experiments have, so far as I know, been made with manganese glasses made with potash and with soda batch mixtures and exposed to sunlight for a long period. It is a matter for regret that, when the old tinted window glasses were examined for manganese, the idea of the influence on the colour of the alkalies present did not occur. [Having regard to the effect of manganese greatly to enhance the phosphorescence of potash and soda-lime glasses, and to the known colouration of certain potassium and sodium compounds under cathode discharge, it is possible that the colours in the old window glasses described are not due to manganese dioxide itself, but that manganese may have rendered the alkali compounds in the glasses more sensitive to light of short wave lengths. The fact that glasses containing no manganese did not colour under cathode discharge, etc., is not conclusive, since such glasses showed but feeble phosphorescence. The observation, however, that of two glasses containing the same amount of manganese, and giving equal phosphorescence, the one, in which there is evidence of some of the manganese being in the higher state of oxidation, becomes very markedly coloured by

an amount of exposure to rays which has no visible effect on the other glass in which the lower oxide of manganese only is present, seems at least to point to some special behaviour of manganese dioxide.]

The influence of different alkalies and the remarks already made on the effect of varying the relative proportions of bases and acids on the copper glasses, bring me to a short consideration of the behaviour of colouring agents which would generally be placed in group (*b*) as existing in glasses in a state more nearly resembling that of true solution than that which may be considered to obtain in the more colloidal solutions of gold, copper, selenium, and other substances such as silver, sulphur, carbon, etc., with which there has been no time to deal. I must confine my remarks to but few of group (*b*), and perhaps nickel and cobalt will be the most suitable to illustrate the effect of different alkalies and also that of varying proportions of one and the same alkali.

If three similar and moderately soft glasses be made containing respectively potash, soda and lithia as the alkalies present in chemically equivalent proportions, and if the same amount of nickel oxide be present in each glass, marked difference in the colours is observed. The potash glass is a fine deep violet, the soda glass is almost brown with only a hint of purple in the brown, and the lithia glass is a yellowish brown with less strength of colour altogether in it than there is in the soda glass. Similar differences can be seen in beads made from nickel oxide dissolved in the bi-borates of the three alkalies. Of these alkalies, potash is the strongest and lithia the weakest base. The glasses mentioned would not be described as acid glasses, but as glasses containing a fair proportion of basic to acid ingredients. If highly acid glasses be made with the three alkalies and the same proportion of nickel oxide, the lithia glass is only slightly coloured a brownish yellow, the soda glass is a lighter brown with no trace of purple in it, and the potash glass is rather darker in shade than the soda glass, but a definite brown. Again, very similar results can be obtained in beads of the borates of the alkalies by varying the proportions of acid and alkali, and using the same amount of nickel oxide in each set of experiments. With potash as the alkali the proportions of boric anhydride and alkali and the concentration of nickel oxide can readily be adjusted to show a bead coloured brown when cold, but becoming a definite violet when heated just below a dull red heat. A like change of colour has been observed in experimental glasses made for studying the colours obtainable from nickel.

With cobalt oxide as the colouring agent, the difference between the blue colours of potash and soda soft glasses is not very noticeable; but a similar lithia glass is less coloured, and there is an appreciable violet tint in the colour. If, however, using any one of the three alkalies a highly acid glass containing the same amount of cobalt oxide be made, the difference between it and the comparable soft glass is very marked. There is much less depth of colour altogether. What there is is a somewhat violet blue in the case of the potash glass, a rather lighter and more violet blue in the soda glass, and a still lighter pink violet in the lithia glass. This nearly pink glass goes to a weak but quite distinct blue when heated.

The effect of the alkalies potash and soda on the colour of borates is not so marked in the case of cobalt as it is in that of nickel. Lithia in comparison with them always gives for equivalent proportions a much more decided violet tint in the blue. The influence of the proportion of base to acid, however, is marked, and can be very well seen, by using any one of the alkalies in varying proportions with molten boric anhydride, to which a small amount of cobalt oxide (about 0·25 per cent.) has been added. [Cobalt oxide dissolves in highly heated boric anhydride, but on cooling cobalt borate separates out, giving an opaque, very pale blue, glassy mass.] Taking lithium carbonate as the alkali and adding only a very small amount (about 0·25 per cent.) the whole of the cobalt remains in solution on cooling, and the resulting glass is seen to be blue while still hot, to change to a more and more violet tint on cooling, and to be almost a pink when cold. The addition of more of the alkali intensifies the blue colour, giving greater depth of colour, and the mass when cold is a violet blue. Similar variations in colour can be obtained with equivalent quantities of potash and soda, but the effect of these alkalies is always to give a more pronounced blue as the amount of alkali is increased. Comparing the weakest base, lithia, then with potash the strongest, and progressively adding each to borate beads containing cobalt, no amount of lithia, up to the point when it is impossible to keep the bead vitreous, will give as blue and as strongly coloured a bead as the equivalent, or even less than the equivalent, of potash will produce. There is always a more violet tint in the lithia bead.

In conclusion, a brief reference may be made to another colouring agent, copper oxide. This oxide is not soluble in boric anhydride when a bead of the latter is heated in an oxidising flame, but by the addition of an alkali a clear blue bead is obtained. Should the alkali, *e.g.* potash, be added in very small amount, so as to give a highly acid mixture of about the composition, for instance, represented by the portions $K_2O.5OB_2O_3$, the colouration due to about 0·25 per cent of copper oxide is so faint that the bead is practically colourless, although this amount of the oxide is sufficient to give a markedly blue bead in potassium bi-borate, $K_2O.2B_2O_3$. In this case, also, then the colour becomes more intense as the amount of alkali used is increased.

One is tempted to compare this effect of alkali on the copper oxide and boric anhydride mixture with that of water on copper sulphate, which, in the anhydrous state, represented by the formula $CuSO_4$, is white. The addition of water sufficient to give the composition $CuSO_4.H_2O$ leaves the substance still white; but with more water the well-known blue copper sulphate $CuSO_4.5H_2O$ is produced. Without going so far as to call this an example of hydrolysis by water, it may not be too much to speak of the development of colour as indicating in $CuSO_4.5H_2O$ a greater tendency to the formation of blue copper hydroxide than is possible with the smaller mass of water in $CuSO_4.H_2O$.

The notion that there is an analogy here with the progressive development of colour in glasses and borates with increase of alkali may be suggested but with reservations. Still, the changes from brown to violet in the case of nickel, from pink to blue in the case of cobalt, and the progressive development of the colour of copper, all brought about by increasing the proportion of alkali, do seem to point, if not to a definite separation out of the oxides of these metals, to something like it in the sense that with very little of the alkali present the oxides of the metals may be playing a basic part, but are turned out by more of the stronger base (the alkali), and may be either freed or caused to play the part of acids to the alkali. The study of a wide range of colouring agents in glasses has furnished some facts which, from a chemical point of view, lend plausibility to the notion and others which seem to need a great deal of interpretation to support it. As an idea it has been useful in suggesting methods of producing as well as of preventing, colour in glasses. More facts, however, must be accumulated for a fuller and more correct shaping, in its physical and chemical aspects, of one of the many interesting problems connected with glass.

THE CHAIRMAN (Mr. Campbell Swinton), in proposing a hearty vote of thanks to Sir Herbert Jackson for his intensely interesting lecture, said the experiments which had been shown revealing the beautiful colours which were to be obtained by putting gold into solutions and into glass were exceedingly old. He understood that the beautiful colours in the glass that existed in many cathedrals had been produced in that way by the monks in the Middle Ages, although of course they were not as familiar with the chemistry of the subject in those times as the lecturer was at the present day. He was sure the audience would agree that the lecture was worthy to rank with the first Trueman Wood Lecture, which was paying a very high compliment to Sir Herbert Jackson, as the first lecture was of the highest order.

SIR HENRY TRUEMAN WOOD said he desired to avail himself of the privilege of seconding the vote of thanks, firstly, because it gave him the opportunity once more of expressing his deep appreciation of the very high compliment that was paid to him by the Council of the Society a year ago when he resigned the office of Secretary; and, secondly, because he wished to express his gratification that the series of lectures, which was so well inaugurated by the masterly exposition given by Sir Dugald Clerk of the principles of the application of science to industry, had been carried on by the admirable discourse which Sir Herbert Jackson had delivered, illustrating the problems which arose in trying to apply scientific improvements to the details of one particular industry. It was a great pleasure to him that the lecture should have been given by his old friend Sir Herbert Jackson, who first appeared before the Society thirty-five years ago, as assistant to Professor Thomson, then Professor of Chemistry at King's College, in the excellent lecture Professor Thomson gave on Crystallisation. Since that time he had rendered many services to the Society, and had frequently taken part in its proceedings. He had heard Sir Herbert lecture on various occasions, but he had never heard him speak more effectively or illustrate his remarks better. He hoped that future lecturers would continue the course which had been so well begun, and that the lectureship would be not only a credit to the Society but also a help to British industries.

The resolution of thanks was then put and carried, and, SIR HERBERT JACKSON having briefly acknowledged the compliment, the meeting terminated.

OBITUARY.

ALEXANDER IZAT, C.I.E., M.INST.C.E. — Mr. Alexander Izat, the well-known Indian railway engineer, died at his Scottish residence, Ballilesk, Dollar, on January 2nd, at the age of seventy-five. He commenced his long career in 1863 as a young assistant in the Public Works Department, and retired after nearly thirty years' very active service with the reputation of having initiated and carried out larger additions to the Indian railway system than any other single individual. In 1883 he was "lent" by the Government to the Bengal and North-Western Railway as Agent and Chief Engineer, and after his retirement he became successively managing director and chairman of the Company. He resigned the chairmanship twelve months ago, but retained his seat on the board of directors. He was also a director of several other important Indian companies. His Companionship of the Indian Empire was conferred in 1898. Mr. Izat joined the Royal Society of Arts as far back as 1881.

GENERAL NOTE.

OSCILLATIONS OF A HIGH CHIMNEY. — The *Engineer* draws attention to the investigations conducted by Professor Omori into the movements of the top of a high chimney when subjected to wind pressure. The chimney observed is built of reinforced concrete, 570 ft. high, and 26 ft. 3 in. inside diameter at the top, and is situated at Saganoseki. Wind velocities were recorded ranging from less than one mile per hour to a hurricane velocity of 78 miles. The amplitude of vibration at a velocity of 50 miles per hour was less than one inch, while at 78 miles per hour it was 7·32 inches. The maximum amplitude was in a direction at right angles to that of the wind. Professor Omori thinks that with wind gusts of 110 miles an hour, which occasionally occur in Japan, the amplitude would be at least 15 inches. The period of vibration was nearly constant for all velocities, varying only from 2·52 to 2·56 seconds.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

JANUARY 21.—ALFRED H. POWELL, "Ancient Cottages and Modern Requirements." The Right Hon. EARL FERRERS will preside.

JANUARY 28.—SIR CECIL HERTSLET, late H.B.M. Consul-General for Belgium, "The Ruin and Restoration of Belgium." EMILE CAMMAERTS will preside.

FEBRUARY 4.—ALFRED E. HAYES, General Secretary, English Language Union, "The English Language and International Trade."

FEBRUARY 11.—LIEUT.-COMMANDER NORMAN WILKINSON, R.N.V.R., O.B.E., R.O.I., R.I., "Naval Camouflage."

FEBRUARY 18. — SIDNEY PRESTON, C.I.E., "English Canals and Inland Waterways." NEVILLE CHAMBERLAIN, M.P., will preside.

FEBRUARY 25. — JAMES CURRIE, C.M.G., Ministry of Labour (Training Department), late Principal, Gordon Memorial College, Khartoum, "Industrial Training."

MARCH 3.—WILLIAM JAMES GARNETT, First Secretary, H.B.M. Diplomatic Service, "Mongolia from the Commercial Point of View."

MARCH 10.—H. M. THORNTON, "Gas in relation to Industry and Housing."

Dates to be hereafter announced :—

AIR-COMMODORE EDWARD MAITLAND, C.M.G., D.S.O., "The Commercial Future of Airships."

BRIGADIER-GENERAL SIR HENRY P. MAYBURY, K.C.M.G., C.B., M.Inst.C.E., "Road Transport."

CHARLES H. SHERRILL, "Stained Glass."

LADY INGLEFIELD, President, Buckinghamshire Lace Association (North Bucks and Bedfordshire), "The Hand-made Lace Industry."

GRAILY HEWITT, "Rolls of Honour."

CHARLES CROWTHER, "The Arts and Crafts of Japan" (with examples from the author's private collection).

WILLIAM CRAMP, D.Sc., M.I.E.E., "Pneumatic Convoying Plants, with special reference to the Transport of Grain."

L. GASTER, "Industrial Lighting in its relation to Efficiency."

BRIGADIER-GENERAL LORD MONTAGU OF BEAULIEU, C.S.I., "Roads and Transport in India."

SIR GEORGE CUNNINGHAM BUCHANAN, K.C.I.E., M.Inst.C.E., "The Ports of India: their Administration and Development."

SIR VALENTINE CHIROL, "The Enduring Power of Hinduism." (Sir George Birdwood Memorial Lecture.)

SIR FRANCIS WATTS, K.C.M.G., D.Sc., Imperial Commissioner of Agriculture for the West Indies, "Tropical Departments of Agriculture, with special reference to the West Indies." LIEUT.-COLONEL SIR DAVID PRAIN, C.M.G., C.I.E., LL.D., F.R.S., Director of the Royal Botanic Gardens, Kew, will preside.

G. F. SCOTT ELLIOT, M.A., B.Sc., F.R.G.S., "Trade Routes for the Empire in Africa."

PROFESSOR WILLIAM A. BONE, D.Sc., Ph.D., F.R.S., "Lignite."

INDIAN SECTION.

Thursday afternoons, at 4.30 p.m :—

February 19, March 18, April 15, May 20.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 p.m.:—
February 3, March 2, May 4.

CANTOR LECTURES.

Monday evenings, at 8 p.m.:—

CAPTAIN H. HAMSHAW THOMAS, M.B.E., M.A., F.G.S., Fellow of Downing College, Cambridge, and formerly of the Royal Air Force, "Aircraft Photography in War and Peace." Three Lectures.

Syllabus.

LECTURE I.—JANUARY 19.—The taking and production of aerial photographs—Development of the aeroplane camera during the war—Type of photographs obtained—Dark-room work.

CHARLES FREDERICK CROSS, B.Sc., F.R.S., F.C.S., "Recent Research in Cellulose Industry." Three Lectures.

February 16, 23, March 1.

WALTER ROSENHAIN, B.A., D.Sc., F.R.S., Superintendent, Department of Metallurgy and Metallurgical Chemistry, National Physical Laboratory, "Aluminium and its Alloys." Three Lectures.

April 12, 19, 26.

ARTHUR THOMAS BOLTON, F.R.I.B.A., F.S.A., Curator, Soane Museum, "The Decoration and Architecture of Robert Adam and Sir John Soane, 1758–1837." Three Lectures.

May 3, 10, 17.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JANUARY 19...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Captain H. H. Thomas, "Aircraft Photography in War and Peace." (Lecture I.)

Post Office Engineers' Association, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5.30 p.m.

Victoria Institute, Central Hall, Westminster, S.W., 4.30 p.m. Dr. A. T. Schofield, "The Psychology of the Female Mind."

East India Association, 7A, Tothill-street, Westminster, S.W., 3.45 p.m. Miss F. R. Scatcherd, "India and her Friends: Wise and Otherwise."

Surveyors' Institution, 12, Great George-street, S.W., 7 p.m. (Junior Meeting.) Mr. R. E. A. Dash, "The Housing Question and how it is affected by Recent Regulations."

Geographical Society, 135, New Bond-street, W., 8.30 p.m. Colonel J. Tilho, "Tibesti to Darfur."

TUESDAY, JANUARY 20...Petroleum Technologists, Institution of, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5.30 p.m. Mr. H. Moore, "Spontaneous Ignition Temperatures of Liquid Fuels."

Statistical Society, 9, Adelphi-terrace, W.C., 5.15 p.m. Mr. G. H. Knibbs, "The Organisation of Imperial Statistics."

Royal Institution, Albemarle-street, W., 3 p.m. Sir John Cadman, "The Modern Development of the Miner's Safety Lamp."

Photographic Society, 35, Russell-square, W.C., 7 p.m. Mr. T. H. B. Scott, "Pictorial Suggestions."

Mineralogical Society, at the Geological Society, Burlington House, W., 5.30 p.m.

Metals, Institute of (Birmingham Local Section), Chamber of Commerce Buildings, New-street, Birmingham, 7.30 p.m. Dr. W. H. Hatfield, "Season Cracking."

WEDNESDAY, JANUARY 21...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Mr. A. H. Powell, "Ancient Cottages and Modern Requirements."

Aëronautical Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m.

Meteorological Society, at the Royal Astronomical Society, Burlington House, W., 5 p.m. Sir Napier Shaw, "Pioneers in the Science of Weather."

Geological Society, Burlington House, W., 5.30 p.m.

Japan Society, 20, Hanover-square, W., 4.30 p.m. Major J. J. O'Brien Sexton, "Colour Prints of Harunobu and others."

Literature, Royal Society of, 2, Bloomsbury-square, W.C., 5 p.m. Dr. J. W. Mackail, "Collins; and the English Lyric in the Eighteenth Century."

THURSDAY, JANUARY 22...Royal Society, Burlington House, W., 3.30 p.m. Special General Meeting, 4.30 p.m. 1. Professor E. G. Coker and Mr. K. C. Chakko, "The Stress-Strain Properties of Nitro-Cellulose and the Law of its Optical Behaviour." 2. Mr. S. Marsh, "On Alternating Current Electrolysis." Communicated by Professor E. H. Griffiths, F.R.S. 3. Dr. W. H. Eccles and Mr. J. H. Vincent, "The Variations of Wave-Length of the Oscillations Generated by Three Electrode Thermionic Tube due to Changes in Filament Current, Plate Voltage, Grid Voltage or Coupling." 4. Mr. S. D. Carothers, "Plane Strain. The Direct Determination of Stress." 5. Mr. F. Horton and Ann C. Davies, "An Investigation of the Effects of Electron Collisions with Platinum and with Hydrogen, to ascertain whether the Production of Ionisation from Platinum is due to Occluded Hydrogen." 6. Messrs. L. Bairstow, R. H. Fowler and D. R. Hartree, "The Pressure Distribution on the Head of a Shell moving at High Velocities."

Dyers and Colourists, Society of (West Riding Section), Dr. F. M. Perkin, "The Application of Electricity in the Dyeing Industry."

Royal Institution, Albemarle-street, W., 3 p.m. Dr. R. R. Terry, "Renaissance Music in Italy and England." (Lecture II.)

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Sir Alexander Kennedy, "The War Area from Ypres to Verdun."

Electrical Engineers, Institution of, at the Institution of Civil Engineers, Great George-street, S.W., 6 p.m. Mr. J. L. Thompson, "Transformers for Electric Furnaces."

Numismatic Society, 22, Albemarle-street, W., 6 p.m.

Mining and Metallurgy, at the Geological Society, Burlington House, W., 5.30 p.m.

Concrete Institute, 296, Vauxhall Bridge-road, S.W., 7.30 p.m. Dr. J. S. Owens, "The Attrition of Concrete Surfaces Exposed to Sea Action."

FRIDAY, JANUARY 23...Royal Institution, Albemarle-street, W., 9 p.m. Sir Charles Parsons, "Researches at High Pressures and Temperatures."

Metals, Institute of (Sheffield Local Section), The University, Sheffield, 7.30 p.m. Mr. J. A. Morton, "Defects (and their Causes) in the Manufacture of Spoon and Fork Blanks."

University of London, University College, Gower-street, W.C., 5 p.m. Dr. T. Borenius, "Mediæval Art." (Lecture II.)

Physical Society, Imperial College of Science, South Kensington, S.W., 5 p.m.

Mechanical Engineers, Institution of, Storey's-gate, Westminster, S.W., 6 p.m. Mr. E. M. Bergstrom, "Recent Advances in Utilization of Water Power."

SATURDAY, JANUARY 24...Royal Institution, Albemarle-street, W., 3 p.m. Mr. A. Noyes, "Aspects of Modern Poetry." (Lecture II.)

Journal of the Royal Society of Arts.

No. 3,505. VOL. LXVIII.

FRIDAY, JANUARY 23, 1920.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

MONDAY, JANUARY 26th, at 8 p.m. (Cantor Lecture.) CAPTAIN H. HAMSHAW THOMAS, M.B.E., M.A., F.G.S., Fellow of Downing College, Cambridge, and formerly of the Royal Air Force, "Aircraft Photography in War and Peace." (Lecture II.)

WEDNESDAY, JANUARY 28th, at 4.30 p.m. (Ordinary Meeting.) SIR CECIL HERTSLET, late H.B.M. Consul-General for Belgium, "The Ruin and Restoration of Belgium." EMILE CAMMAERTS will preside. The paper will be illustrated with lantern views.

Further particulars of the Society's meetings will be found at the end of this number.

CANTOR LECTURE.

On Monday evening, January 19th, LIEUT.-COLONEL ALLAN J. C. CUNNINGHAM in the chair, CAPTAIN H. HAMSHAW THOMAS, M.B.E., M.A., F.G.S., Fellow of Downing College, Cambridge, delivered the first lecture of his course on "Aircraft Photography in War and Peace."

The lectures will be published in the *Journal* during the summer recess.

SIXTH ORDINARY MEETING.

WEDNESDAY, JANUARY 21st, 1920; The Right Hon. EARL FERRERS in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Adams, Sidney James, London.
Arthur, Major Edmond John, Birmingham.
Ashworth, Arthur, Bury.
Calvert, Alderman Joseph, J.P., Middlesbrough.
Clifford, William John, Brockenhurst, Hants.
Colwyn, Right Hon. Lord, Colwyn Bay.
Croft, Cyril Murton, London.
De Cruez, J. A., London.
Dickinson, Mrs. M., Brighton.
Evans, Joseph S., Commander, U.S. Navy, Washington, D.C., U.S.A.
Froud, Edgar Arnold, London.
Ghatalah, M. H. P., Banganapalle, India.
Goslin, James, Johannesburg, S. Africa.
Greenshields, J. N., K.C., Montreal, Canada.
Griggs, Arthur Robert, Bromley, Kent.
Hart, George Eaton, London.
Hendry, Brigadier-General Patrick W., C.B., Glasgow.
Kelsey, William K., B.A., London.
Knowlton, Elliot Ainsworth, Rochester, U.S.A.
Lawrence, John Edward, London.
Longden, Major Alfred Appleby, D.S.O., London.
Mermoz, Francisco Alberto, Buenos Aires.
Mitchell, John, London.
Mitchell, John M., M.I.Mar.E., Sydney, N.S.W., Australia.
Morrell, Clayton Conyers, London.
Morris, Arthur Percy, B.Sc., Assoc.M.Inst.C.E., Burma.
New Jersey, The Right Rev. Bishop of, Princeton, New Jersey, U.S.A.
Palmer, Austin Norman, New York City, U.S.A.
Penicud, John William, Paris.
Pettigrew, J. Stewart, Glasgow.
Redgate, C., Heanor, Derbyshire.
Rhodes, John Edwin, M.D., Chicago, Illinois, U.S.A.
Sayner, George Smith, Richmond, Surrey.
Shay, Peter Yevent, B.Sc., Sheffield.
Silverman, Professor Alexander, Pittsburgh, Pa., U.S.A.
Spear, William, Edgware, Middlesex.
Stanfield, George John, Carlisle.
Sutherland, Charles H., Nova Scotia, Canada.
Taft, William Howard, LL.D., D.C.L. (Ex-President of the United States), New Haven, Conn., U.S.A.
Tattersall, John, Enschede, Holland.
Vaus, Frank H., London.
Thomson, George Clark, Saskatchewan, Canada.
Walsh, Lawrence J., Southbridge, Mass., U.S.A.
Willis, James Harold, B.Sc., Cardiff.
Woodhouse, William H., Crewe.
Wright, Lieut.-Colonel Clifton Vincent Reynolds, London.

The following candidates were balloted for and duly elected Fellows of the Society:—

Bassett, Frank Owen, London.
Bassett, John Harrold, London.
Clark, Victor Albert Jarvis, London.
Gaunt, Frederick William, Farsley, near Leeds.
Haas, Adolph Louis, A.M.I.Mech.E., London.
Hainsworth, Charles, Farsley, near Leeds.
Hargreaves, Miss Violet, Eccleshall, Staffs.
Holmes, H., Moseley, Birmingham.
Ibbotson, Walter Dudley Boswell, Bowdon, Cheshire.
Kay, Max M., Manchester.
Maurice, Ernest Maurice, London.
Russell, Captain Guy, London.
Salmon, Harry, West Hartlepool.

A paper on "Ancient Cottages and Modern Requirements" was read by Mr. ALFRED H. POWELL.

The paper and discussion will be published in the next number of the *Journal*.

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

A meeting of the Indian Section was held on Friday, January 2nd, 1920; SIR HARVEY ADAMSON, K.C.S.I., M.A., LL.D., Lieutenant-Governor of Burma, 1910–15, in the chair.

The paper read was—

BURMESE VILLAGE INDUSTRIES: THEIR PRESENT STATE AND POSSIBLE DEVELOPMENT.

By A. P. MORRIS, B.Sc., Assoc.M.Inst.C.E.,
Provincial Art Officer, Burma.

The subject of this paper is "Burmese Village Industries: their Present State and Possible Development." It might perhaps have been better had I chosen the word handicrafts instead of industries, since I do not include the greatest of all the village industries—agriculture; but I gather that the exclusion will be understood.

Our Burmese village industries cover a wide variety of crafts. The members of the Indian Industrial Commission who paid us a visit in January, 1918, were struck with the high grade of the craftsmanship, and in the course of their report they say: "The small indigenous industries present several features widely differentiating them in character and organisation from the corresponding industries in India. Considering the size of the industries themselves and the number of persons engaged in them, a relatively large proportion of the articles produced appear likely to command a sale in other parts of the world."

This notwithstanding, the village craftsman is generally poor, poorer than his agricultural brother. This is not due to laziness, as some suppose; the craftsman, take him all the year round, works harder and for longer hours than the agriculturist. But the result of this poor return for skilled work is that there is a gradual defection from the ranks of the craftsmen, the crafts are dying, and the men are not passing to other more remunerative crafts, but to the production of raw materials.

Now, if agriculture and the production of raw materials give better returns to the people, is it worth while worrying about these moribund handicrafts? It would perhaps require a great deal of detailed argument to prove definitely that the decay of handicrafts is bad for any country. It is possibly true of some of the Burmese village industries that it would be better to let them die a rapid natural death, rather than by artificial means to continue them in a state of senile decrepitude. But if I can show that some village industries are desirable, that in some cases the causes which have weakened the industries can be excised and removed by suitable treatment; that certain industries have already been improved by aid of a kind that cannot be called mere benevolent bolstering, then I shall have gone some way to establishing a case for the consideration of schemes for developing the Burmese village industries.

It is manifestly impossible for me to deal with each industry in detail, and I must to some extent classify and generalise, illustrating my points by references to particular industries. For the sake of convenience I have grouped the industries under three heads. (1) Supplementary industries. (2) Whole-time industries, which I would subdivide into (*a*) art industries; (*b*) quantity production industries. (3) Trades. These are arbitrary classifications, they overlap, and some industries might be included in more than one of the groups.

In a note on the development of village industries in the Delta, a recent Commissioner of Bassein says: "I take it that one of the chief causes of crime in this division is the fact that it is a one-crop area (paddy) in which one-yoke cultivators can hardly make ends meet.

They urgently need subsidiary crops or industries to eke out a living. Further, subsidiary industries would, while improving the economic conditions, keep agricultural labourers employed throughout the months when agricultural employment cannot be got. There is no definite prospect of subsidiary crops, and it is therefore most necessary to develop cottage industries, and I think this Division has much to hope for from a careful consideration of its economic conditions by the Indian Industrial Commission." Here, then, is a case where some industries are desirable.

Now it is not possible to make all industries supplementary industries. To be suitable for this purpose an industry should be fairly easy to learn, it should be possible to carry it on at odd times and for irregular periods, and it should not need much outlay for apparatus. This considerably limits the field.

Some of the most suitable industries for the purpose are the various forms of weaving, whether with silk into piece-goods, or of grass, cane, reed, bamboo, or other materials into matting and baskets. These different forms of weaving are practised in the Province, and they are capable of very valuable extensions.

In silk weaving we have an industry which has an assured outlet for its products. The Burmese, men and women alike, wear silk for their holiday attire, and the demand for silk goods is very considerable. The import of silk yarn into Burma from China is valued at 26 lakhs annually, and in addition there is a large import of silk piece-goods. Yet the silk-weaving industry was dying until, on the advice of Mr. Saunders, of the Indian Civil Service, the Local Government secured the services of a weaving expert and started a small school at Amarapura, one of the most important silk-weaving areas in Upper Burma. The school does not aim at instructing novices, but takes villagers already trained in the use of their own looms and gives them instruction in the use of a different type of loom, changing them over from the hand thrown to the mechanically thrown shuttle. This, together with the other instruction given in the school, has so improved the rate of output, without destroying the characteristics of the industry as a cottage industry, that the villagers can now make quite a reasonable profit. By the formation of co-operative credit societies of weavers, the financing of the trained craftsman has been facilitated and the industry is regaining lost ground. Experiments are also being undertaken to determine whether silk can be grown on a large scale in the Shan States. It is too early to give a definite answer to this question, but it seems likely that the experiment will succeed, and if so this will do a great deal to ensure the success of the industry.

The disadvantage of the centralisation of instruction in a weaving institute is one inherent in all attempts to foster a subsidiary industry which will engage a large number of workers whose homes are spread throughout the country instead of being concentrated in a small area. While it is not difficult to get people from near by to attend the school, the villagers will not readily go to the other end of the Province to learn a trade, and the school at Amarapura does not easily attract people from a long distance. The educational work must be begun from some point, and it is necessary to have an establishment under the control of a really highly qualified expert, both to initiate the training, and to test the possibility of establishing an industry. But once it is found that the industry can be made to pay its way, the Central Institute is not enough. This is true perhaps of all technical education, but in the higher grades a single institute can, and on account of expense must, suffice for a large area, but in a lower grade of technical training you cannot expect the pupils to go far, your radius of efficiency decreases, and you must take your education to the pupils. This means that either the Central Institute must be itinerant, moving from one centre to another and only staying in each area long enough to establish the industry, or the Central Institute must be made a training-ground for instructors, and these instructors can then be sent out into the villages to establish training in the schools. This is perhaps more practicable, but it is necessary for the expert to supervise carefully the work of these instructors, and not to leave supervision to the ordinary schoolmaster, for there is always some danger of the training, under less expert instructors, falling to a lower standard.

But by supplying a supplementary industry for a large number of workers the output will probably rise beyond the local demands, and we then have to meet the question of marketing. This necessitates organisation of a type more advanced than mere co-operative loan societies, and in this respect the work done by the American Education Department in the Philippines is worth quoting. My source of information is a periodical published in the Philippines; I obtained a few numbers in Burma, and while the outline now given is incomplete from the

nature of my references, it gives some idea of the general scheme. The problem seems to have been somewhat similar to ours—the need of subsidiary industries, and one of those taken up was mat and basket work. Roughly speaking, the method is to give instruction in the schools taking an industry as part of the curriculum. By the time the pupils leave school they have in their hands a possible subsidiary industry. On the industrial side the organisation is carried on by bureaux which, on the one hand keep traders informed of the products available, and if necessary act as agents, and on the other hand supply the schools with ideas for new developments of the industry. The schools are the centres for testing new ideas, and the bureaux pass on the results of successful experiments from one area to another. It needs intelligent co-operation between the bureaux and the educational authorities, but that is only a matter of efficient organisation.

So far in Burma, except for recent work on silk weaving, we have not been very successful with education in subsidiary industries. There have been spasmodic attempts to develop industries; lack of really expert instruction, disregard of the economic problems involved, attempts to make income out of instruction, and other causes, have been at the base of the failures. Perhaps the most promising attempt was that made in the Roman Catholic mission school at Thonze, where some excellent mat and basket weaving was done, but the course was crowded out by the demands of the official school curriculum.

In Burma we have an abundance of excellent mat and basket material, and I believe that, if the complete organisation which I have outlined were instituted, we could do much to keep the Delta supplied with subsidiary industries. But it must be a complete organisation. You cannot do the education alone and leave the marketing to private enterprise, certainly not for the first years of the industry. The little trader is not an economical collector or distributor, and he cannot pay the craftsman a reasonable wage; he absorbs too much himself. On the other hand a large firm is not likely to take up the work; it has too much of the nature of an experiment about it. It seems to me that this is just one of those cases where experiment is justified and necessary. Like all experimental work it will be something of a gamble, but a reasonable balance of successes may be expected.

The Weaving Institute has dealt only with adults in a whole time course. Personally, for the establishment of a subsidiary industry, or indeed for any industry, I would favour a slower course with younger people. Here again I would instance the work in the Philippines, and I quote verbatim from a book by Dean C. Worcester, who was from 1900 to 1913 Secretary to the Interior in the Philippines: "Previous to 1909 industrial education was only partially organised. Experience had shown by that time that it was expedient to introduce a degree of specialisation into the course of study at an early stage of the child's development. Special intermediate courses were, therefore, organised to meet the need. After finishing the four years' primary course the child may choose between a course of teaching, a course of farming, a trade course, a course in house-keeping and household arts, and a general intermediate course. Relatively few children are at present able to take up secondary courses, and it is therefore necessary to provide in the lower grades for instruction which will prepare them for some vocation. So important has become this line of instruction, that it has been found necessary to maintain in the general office an industrial information department." Again the same writer, quoting from an official report, says that out of 235,740 boys and 138,842 girls, 216,290 boys and 125,203 girls are taking some form of industrial work; of this number 30,000 are engaged on hat making, 40,000 are making mats, and 104,000 are doing basketry. Apparently from the figures some children learn more than one industry.

Now apply that to Burma. Apart from the Anglo-vernacular schools we have a very extensive vernacular educational system based on a ten years' course, but as a matter of fact very few of the pupils go beyond the fifth year. The education given is purely literary, except for a very small amount of "hand and eye" training. It is good in its way, but unless the student goes on to the tenth year it really does not lead to much, it fails to establish anything. It is on this course that I would suggest that we should graft, as the American Educational Department has done, some form of vocational training in subsidiary industries. It need not in any way lower the value of the intellectual training—quite the contrary; but it will leave the pupils better equipped for life.

There is one danger about craft-training which needs careful watching, and that is the attempt in such instruction to teach pupils to run before they can walk, and to make things before processes have been thoroughly learned. This desire is often fostered by poverty, by

lack of funds in the school, for then there is a tendency to attempt to make income out of instruction. This is fatal to good instruction, and no finished product should be made beyond what may be necessary to stimulate interest, unless the pupil has first thoroughly mastered the necessary skill. But I certainly prefer to give craft-training as an extension of schooling, to work on material still amenable to school discipline, rather than to work on the adult with set ideas. The child learns new processes more readily, and is not so anxious to get away to make money before the instruction is complete.

I now turn to my second group, the Art Industries. The Burmese as a people have a natural talent for art, they have a keen sense of colour, and considerable decorative ability. To make matters clear I must attempt to sketch in as quickly as possible the position of these industries. Under the term art industries I include all the work in silver and other precious metals, ornamental work in the base metals, bronzes, carving in wood, ivory carving, and all work, in fact, in which the main characteristic is beauty rather than utility. Apart from the question of beauty, the characteristics of these art industries are that the workers are whole-time workers, and from the nature of their work they are comparatively few and isolated.

Under the Burmese *régime*, the possession of vessels of gold and silver was limited by sumptuary laws; the craftsmen, as in Mediæval Europe, lived on the patronage of the Court, and whilst the payment of their dues was probably erratic, it is likely that they did fairly well. The woodcarvers had ample demand for their skill in the decoration of religious structures, and generally speaking the art workers found plenty of scope for their abilities. To-day, instead of a Court with its glittering throng, we have a crowd of clerks toiling in a Secretariat. The Secretariat *quâ* Secretariat can scarcely be regarded as a patron of the arts, but on the other hand the sumptuary laws have been repealed and all who can purchase art wares may do so. The woodcarving industry has suffered from the changed times, there is no longer any great demand for the beautiful carving so abundant on the old structures. With the rising price of timber, and the introduction of a variety of new structural materials, wood is going out of fashion. The times and the fashions are changing, and if the art industries are to revive they, too, must change. Some say that we must preserve the old arts; the craftsmen, according to them, must study the work of their forefathers, and not depart from it. Now, of course, the study of the best in ancient craftsmanship is necessary and inspiring; but the old artists whose work these people admire were experimentalists, and for every masterpiece which has survived, many less successful experiments have been forgotten. A change there must be, for art which is not experimental—which does not create—ceases to be art, it becomes mere imitation, it stagnates, it dies. A change there must be, for the conditions and the demands have changed, the old designs and articles are not wanted, and sad though it may be, an art industry which does not provide bread and butter is not likely to attract recruits, and it will disappear. But if there is any vitality in an industry it should move forward of its own accord and keep pace with the times, and so these art industries might have done had the said changes been normal developments, had the pace not been forced. Things being as they are, some external help is necessary, and it becomes a question how much help can be given, and what should be the nature of that help.

I can best justify such suggestions as I have to make by reference to what has been done. We have in Rangoon an annual art handicrafts exhibition, the establishment of which was, I think, chiefly due to Mr. Tilley, some time Commissioner in Burma. The silversmiths had been accustomed to make figures in silver, these figures being conventional but gracefully shaped. Mr. Tilley suggested to some of the craftsmen that they might turn their hands to bronzes. The first attempts were stiff and formal, with little to commend them, but Mr. Tilley introduced into the exhibitions a regular system of competitions for this work, and helped the craftsmen by criticism and advice, not attempting to design, but pointing out to them where they failed. And now we have an established industry in these bronze statuettes, and the best among them would attract attention anywhere. Now this was a new departure, and the factors which made for success were, first of all, that the suggested work was within the ability of the craftsmen; secondly, they were able to appreciate the idea; and, thirdly, there was a ready market to encourage attempts.

Now let us take the woodcarving industry. The old woodcarving was practically all of it done in connection with architecture; it was applied as ornament on religious structures, and in itself was not part of the structure—it had

to bear no strains. As ornament of this kind it was bold and not very finished, and sufficient relief was supplied by the unornamented spaces. But, as I have stated, this industry is failing, the demand for architectural woodwork is decreasing. In this case the industry must find some new outlet, and well-wishers have suggested all sorts of things for the woodcarver to make, chiefly articles of European furniture. He has, for instance, been called on to make a chair. But he has no use for a chair himself, he does not understand the features which must be studied in the design of European furniture, and he consequently regards the chair merely as something on which to exercise his skill as a woodcarver. And the result is a prickly monstrosity, which is inelegant, uncomfortable, and unsafe. It is not the fault of the craftsman, it is that he has been induced to venture beyond his powers of appreciation, or rather, beyond his powers without some further information and training: training not only in the old traditions of woodcarving design, but in the use of new timbers suitable for interiors, in more accurate joinery, if the work is to come under closer inspection than that to which it has been accustomed as architectural ornament, and training also in the design of new articles.

As a third example, I take the black pottery industry. The black pottery process, or, to be accurate, the blackened earthenware process, is not confined to Burma. This type of ware is made in India and other places. But it reaches a high grade in Burma, and the ware has a very attractive texture. The industry is not exactly an art industry in respect of its main product at present, but recently the potters have turned their hands to the production of ornamental wares, and the annual art exhibition has done much to bring them to popular attention, while we have also been able to help the potters by sending their wares to other sales, thus securing publicity. The potters had of their own initiative attempted to ornament the pottery by producing designs on the surface partly in matt and partly in glossy black, but they were hardly distinct enough to be attractive. A little research work was put in hand at Insein, and a process was discovered which gives the potters a means of making a very attractive red figured black ware. Here a process has been put in the hands of the potters, one which they can readily use, but the design of the pattern has been left to them. The process will enable them to produce an art ware which can be sure of a ready sale at good prices. There is sufficient evidence already for us to be confident of that, and the potters will be considerably benefited by the new outlet for their abilities.

These are instances of what has been done, and they seem to me to indicate what can be done to help the potters. In the first case the problem was comparatively simple and success was soon achieved; in the second case the problem was more difficult and no great success can be recorded as yet, though there is room for hope; in the third case a new process has been placed at the disposal of the craftsmen, and they have already shown their ability to profit by it. I think we can say that the lines indicated are:—

(1) To assist the art workers to obtain a better market by bringing them in touch with purchasers.

(2) To help them in their processes by improving their tools.

(3) To give them new suggestions, provided that these suggestions do not go beyond their scope and comprehension, and when necessary to give them advice on, and to help them to overcome, difficulties in following the suggestions.

All this is on the technical and financial side. If the arts are to retain their national characteristics, the peculiar genius of the race, as they should do, I would advance very cautiously in the matter of design, indeed, I am personally doubtful whether anything much can be done. Certainly not till educated Burmans turn their attention to the art crafts, and towards this there is as yet little evidence of movement. Of course, when the new article is for European use, such as a chair or the silver back of a brush, the general outline must follow lines new to the craftsman, but in this case all detail ornament can and should be left to him. And success can only be expected if the craftsman thoroughly understands the use of the article; for he must, perhaps unconsciously but not the less surely, be guided in his own design by all that has led to the evolution of the shape of the article.

In this the annual Art Exhibition for the Province, especially if it is supplemented as it should be by district exhibitions, is most helpful. The Committees, by the subjects set in the competitions, can help forward the industries, and the craftsmen in competing learn what can be done, and see for themselves, by comparison with their competitors' work, what lines of development are most successful. The exhibitions are also useful on the financial side, for they give the little isolated craftsman a chance to

market his wares, often pretty well his only chance of securing a wide and appreciative market.

I am, however, inclined to think that we might improve on this, and give these art workers an opportunity of selling their products by setting up a sale society in Rangoon. Even now I get a good deal of correspondence from private individuals asking for art materials, and I place out these orders as best I can, but I have not the staff or the time to attend to them efficiently. A sale society in Rangoon, run on a sale-commission basis, need not be run at a loss, and it would be a great gain to the art craftsman. The commission charged should pay the running costs and, according to the relative cost of sales, the rate of commission should from time to time be adjusted.

One word as regards the training of the young art craftsman. The system at present is one of apprenticeship. Youths, often, but not necessarily, the sons of the craftsmen, are taken on and trained, and in course of time they grow up into craftsmen. Government has a small scheme of scholarships which are placed in the gift of the Provincial Art Officer, and he is thus able to encourage some of the leading master craftsmen to pass on their knowledge to the rising generation, and to help the rising generation to study the crafts. But in such an industry as woodcarving where a real change is necessary, this does not effect much good, and I am of opinion that we need a small school of art industries where these art crafts can be studied and better technical methods introduced. In such a school the art instructors should be selected from the Burmese master craftsmen, but of necessity this instruction must be supplemented on the purely technical side by one or two instructors trained in modern methods, and these should in their own lines be master craftsmen too, but not necessarily, in fact preferably not, art craftsmen. A good cabinet-maker and a smith would possibly be all that is required. As a matter of fact, we have done something of the sort in the Government Engineering School at Insein. We have two of the best master craftsmen in Burma, a woodcarver and a bronze worker, resident at the school. These men work for themselves, but they have the young Government apprentices in these crafts placed under them. In addition, these young apprentices spend some time in the school shops where, under the eyes of the technical instructor, a Scotsman of high skill and strict discipline, they learn something of good workmanship. One boy, a young woodcarver, is doing very well, and his elder brother has taken a course of cabinet-making under the same instructor and is turning out a first-class worker. The two have made up their minds that when their training is finished they will set up jointly as manufacturers of furniture, and their joint skill should produce some interesting results.

As a second sub-division of the whole-time industries, there are those industries which I have classified as quantity production industries. Here the artistic element may or may not be present, but the chief characteristics of the group are that large quantities of similar articles are produced and the number of workers is far greater than in a high-class art industry. Speaking generally, these industries are localised in areas, a village, or small group of villages, having the industry as its chief occupation and supplying the needs of a wide area or possibly the whole province; the workers exhibit great ability, but their tools are primitive; the popular demands are in many cases tending to change more rapidly than the products of the industries; and the craftsmen are as a whole miserably poor. It is especially difficult to generalise about this group, and I will take one particular industry first, and then, if I may, illustrate some of the points from other industries.

I take as the typical industry that of the lacquer workers. There are two main centres of production, Pagan, on the Irrawaddy, and an area in the Chindwin District. The chief raw material, the material which is used in preparing the lacquered surface, is known as *thitsi*; it is not found in the area where the industry is carried on, but is imported from comparatively distant parts of the Province. The other materials are bamboo and a few pigments. At Pagan there are some 1,500 people constantly employed in the work, while there are many more engaged as a part-time occupation in weaving the bamboo frameworks to which the lacquer material is applied. The bulk of the wares are crude articles of domestic use, boxes, trays, and bowls, but the highest skilled workers carry the industry up to the level of an art industry. Practically the whole of the output is sold within the Province, only some of the more expensive art wares, and an inconsiderable quantity of the other wares, find purchasers among the European population, and only a very small amount is exported. The cruder wares now have to face the competition of imported enamelled iron and other

articles, and this has prevented a rise in price for local lacquer wares to meet the increased cost of living. There has also been of late years a considerable and growing import of Japanese lacquered wares, which are finding a ready sale among the Burmese, and these wares are made from a material exactly the same as the Burmese wares so far as the lacquered surface is concerned. I estimate that, speaking roughly, the value of the annual output of Pagan, the amount paid to the craftsmen for their wares, is about six lakhs, and the value of the same wares as retailed is not less than 20 lakhs. The craftsmen work independently or in family groups, purchasing their materials in small quantities, and in some cases, as already mentioned, purchasing the made-up frameworks of the articles. The poor income they make renders them unable to accumulate stocks, and as a general rule they live on advances from traders and sell their wares at the traders' prices.

Now these craftsmen, like all craftsmen, are very conservative, and they do not change their methods and products readily. I do not mean that they are incapable of progress. I could show you that in this industry with which I am dealing there have been changes in the last fifty years, changes which have been introduced by the craftsmen themselves. But the social conditions of the Province have been pushed forward centuries in as many decades, and with this change has come a change in the popular demand for materials. This change has been forced from without, and the craftsmen, left without a commensurate external stimulus, have only gone forward at a normal rate of growth. The crude wares which satisfied the customers of their forefathers do not now attract much popular attention, and they have to sell their wares in an indifferent market, which takes them only at a low price.

Last year a few experiments were made in the manufacture of other articles, and it was shown that some of these would find a ready market at prices which would give a much greater remuneration to the craftsmen. Such work needs to be carried further. The crude wares do not give and are not likely to give adequate remuneration, but the whole of the *thitsi* which the Province produces can be quite well deflected to the manufacture of more remunerative lacquered articles, and if this is done the master craftsmen will still be able to continue their industry as an art industry. It is not a question of high research in distant laboratories, for though the work in the laboratories may be useful, what is far more necessary is patient research in the industrial villages working step by step with the craftsmen in the improvement of processes, and in the production of articles which will find a more ready market. Just as the changes in social conditions and industrial demands have been speeded up by abnormal causes from outside the Province, so the craftsmen's ideas and methods need to be improved by external help to enable them to bridge the gap in the centuries. This does not necessarily mean the exploitation of the craftsman, or the destruction of village industries; quite the contrary.

But there is another line along which much can be done to develop the industries and improve the prospects of the workers, and that is in the matter of organisation. Recently a co-operative loan society has been started at Pagan, and while it is too soon to give any account of results, this co-operative society cannot fail to ameliorate the financial condition of the members, and to put them in a stronger position as regards the holding of stocks and the handling of orders, while they should be able to benefit to some extent by purchasing their materials in bulk at cheaper rates. There is still a demand for lacquer ware in the Province, and there would be a much greater demand were the craftsmen to modify their output to suit present needs. The workers, however, are so anxious to secure sales that they undersell one another to the limit of their ability and thus keep their profits down to the starvation point. Loan societies will not help them here, the co-operation must be carried into production.

I spoke just now of the imports of Japanese lacquer ware. As compared with Pagan ware the Japanese ware is more highly finished on the surface and the shapes are more in accordance with modern demands. I am, of course, not speaking of high-class Japanese lacquer which has national characteristics, just as the high-class Pagan ware has its own characteristics. I am thinking of comparatively cheap wares. There is no reason at all why the Pagan craftsmen should not make all these articles, and put them on the Rangoon and Indian markets at the rates they now fetch and at considerable profit to themselves. There is no reason, that is to say, provided they follow possible lines of progress. They can at present produce this high finish, but only at considerable expenditure in labour. The secret is to change from a bamboo to a wooden framework, and to make one or

two quite simple alterations in the process of lacquering. But here the craft suffers, as many Burmese crafts suffer, from isolation; single crafts occur in village areas and the crafts with which they need to combine are only practised in other village areas. It will be necessary to introduce carpentry on a big scale into Pagan; timber can be had in plenty by transport down the river from the forests.

Now the problem, as it seems to me, is largely educational, using the word in a wide sense; but I believe a great deal might be done by education in the narrower sense. I have already referred to the vernacular education system of the country, which, excellent as it is, does not lead very far, and in a village area with a distinct industry I see no reason why the education should not be made vocational for some of the villagers, as I have suggested for supplementary industries. I would take in this case the special vocation already indigenous to the area and teach it as an optional side of part of the vernacular curriculum, not greatly altering the curriculum for these students, but making it centre round the industry. I would suggest introducing carpentry in addition for the senior students, not from the point of view of its "hand and eye" training value, but as a definite introduction to the craft. If carpentry were introduced into the vernacular schools at Pagan and taught properly by a really qualified man a good many of the pupils would doubtless drift away to other centres where they would find lucrative employment. But the Burman is "a homing bird," and if he can find reasonably good employment in his own village he prefers to remain there, so a sufficient number of young carpenters would stay to carry the lacquer-ware industry forward to the making of all those articles now imported from Japan.

Quite recently, with the help of the Indian Trades Commissioner, I held a small exhibition of Burmese village wares in London. The exhibition was not open to the general public, but was meant for traders in Oriental wares and others who might care to take up the marketing of our Burmese village products in Europe. The result was most interesting, and the views expressed were as contradictory as it is possible to imagine. A particular line of goods would seem to one dealer suitable for import and likely to find a ready sale, while another line in his opinion had no chance on the European market. His successor would absolutely reverse the order and show keen enthusiasm for the wares which his predecessor had condemned. But there is one point which, apart from high-class art wares, will certainly be a weakness with the Burma village industries for some time to come. The home importer wants quantity; he talks of an order for several thousand pounds' worth of certain goods, and when you say you could only supply as many hundred pounds' worth he shrugs his shoulders and goes away. Now, that is a weak point. The quantity production village industries need this export trade; they cannot immediately produce the quantities required by exporters, and the exporters will not give them orders such as they could work up to immediately. It is true that the lacquer industry at Pagan has, as I have said, a value of some lakhs of rupees, but a great part of this will always be absorbed by the Province, and anyhow at present only a very small proportion would be worth exporting to Europe. But it is the export trade which will really help them, and they must try to secure it. And, indeed, the Pagan lacquer industry is the least convincing example I could have taken in regard to this point, because it has a fairly large output concentrated in a small area. This, of course, facilitates trading. With most of the village industries the output of any one individual group is nothing like as large as this. And here it seems to me there is need for action in the way of helping these workers to organise sufficiently to enable them to take up big orders and to secure the confidence of firms in England. Until such organisation is sufficiently developed, industrial bureaux, such as I have described, would be useful as go-betweens to link up the craftsmen and the European importers. Co-operative loan societies are not sufficient. The development of organisation is a change which the craftsmen cannot accomplish alone; they need help because the change is too great for them, too sudden for them to evolve naturally. If this matter could be left to private enterprise, private enterprise would already have accomplished it; all that private enterprise has accomplished so far is to absorb the greater portion of the retail prices by uneconomical collection and distribution, and thus to speed the decay of the industries. Now, it may be said, "That is all very well, but lacquer is only one industry; you may perhaps have made a reasonably attractive picture of the possible development of this industry, but are the others equally likely to succeed?" My reply is that I have too much compassion for my audience to presume on their patience by taking each industry in turn and dealing with it in detail.

The treatment in each case must be different, owing to the particular and peculiar difficulties of each industry. I could show you that conservatism all but killed the Burmese umbrella industry, which was rapidly dying chiefly owing to the fact that the Burman learned to prefer the crooked handle of the European umbrella in place of the straight handle of the Burman article, and it was not till the Burmese makers learned at last to use crooked handles that the industry began again to come into its own. I could give you other instances of uneconomical distribution, such as that in the black pottery industry, where articles made at Letthit are sold in Mandalay, twenty miles away, at prices four or five times that which the craftsman receives. I prefer to call this uneconomical distribution, and leave the question open as to whether the middleman is rapacious or no; sometimes it is rapacity, but in some cases these rates are really due to waste of labour. I could give you further instances of how small experiments carried out with the help of the craftsmen have led to improved methods and sales. Or I might instance how recent experimental work on the use of paddy husk as a fuel in connection with the native type of kiln has gone far to solve the fuel problem for Lower Burma potters whose industry was being killed by the cost of timber fuel. But I should only be repeating the arguments and wasting your time. The points which I wish to make are that these industries suffer—

(1) From the conservatism of the craftsman.

(2) From uneconomical distribution.

(3) From the rapid change of popular demands which have left the craftsmen to-day far behind in the race for trade.

To me it seems these difficulties can be overcome by—

(1) The extension of technical education of a simple type in the vernacular schools, fostering the crafts indigenous to the areas treated.

(2) By organising the craftsmen so that they can themselves deal with wholesale firms in the large centres, and by selling in bulk reduce the costs of distribution and consequently improve their own profits.

(3) By patient experiment side by side with the craftsmen, studying with them the possibilities of manufacturing such things as are in present demand, and meeting the difficulties if possible by simple adjustments of processes. Indeed, if they cannot be met by simple adjustments it is better not to try them.

These quantity production village industries are of great importance; they employ a large number of people, they might be a considerable item in the development of the national prosperity, and they are the natural source of supply for workers in those necessary industries which I have grouped under my heading of trades.

And this is my last group. Possibly I ought to apologise for introducing it at all, but it has a very distinct connection with the subject. By the trades I mean those crafts in which there is nothing of a national characteristic, but which are in their present state absolutely modern, and generally a matter of collective effort. On these trades all modern manufacturing processes and all modern industries depend. I refer to such occupations as the various building trades, and the crafts practised in engineering shops. In such the Burman has at present but a small part, yet building is a village almost as much as a town industry, and the Burman did all his building in the past both in timber and brick. You can see Indian labour employed nowadays on pagodas, a state of things which does not add to the correctness of the details of Burmese architecture. And in the engineering shops only a very small amount of the skilled labour is Burmese. The Burman is found in the moulding shop and at natty work of that sort, and to some extent in the pattern shop, but in all the other shops he is very much in the minority.

The reason for this is that the Burman has not had a fair chance to adjust himself to the rapidly changing conditions. When the railway and other shops were started those in authority needed skilled labour immediately, and they imported it from India. And those in charge of the shops, the foremen and others, often either Eurasians from India or Englishmen trained in India, understood Indian labour and knew how to deal with it, but had no knowledge or understanding of the Burmese. In the same way Chinese carpenters from Singapore flooded the country, and of course the Chinaman has a very well justified character for honesty and hard work which finds him a ready welcome. In the building trades, for modern brick work, Indian labourers already trained are introduced, and so on through all the trades.

I do not see how this could have been helped, anyhow at first. Work had to be done and done efficiently. But the natural sources for craftsmen in new trades are the existing craft industries of a country, and this in itself is a strong argument for the fostering of the existing village industries and helping them to a more

rapid development. And it is here that these trades link up with my main subject.

The work of supplying craftsmen for these trades is wholly educational. This the Indian Industrial Commission to some extent recognise in their report. There is an idea at home that craftsmen must be trained entirely in the workshops by a long apprenticeship, and any attempts at intensive training are resisted. It is indisputable that you cannot finish a craftsman in a school, he must have some part of his training in the shop; but from what I have seen lately of craft training in England I believe that the old seven years' apprenticeship is wasteful, that some years might be saved if the initial stages were done by intensive training in schools. But, be that as it may, in Burma anything except direct educational effort is well-nigh out of the question. The large proportion of Indian labour, and the very mixed type of that labour, makes training of young Burmans in the shops both difficult and unsatisfactory; the wastage is very high. It would be a real saving to the community to give the youths some three years' training in schools, and then let them go to the shops as improvers—often in this case they would on entry into the shop be considerably better than the average so-called skilled Indian labourer employed. And in the building trades there is no apprenticeship possible, while in carpentry the Chinese form a closed guild. In a very small way we have put this to the test at the Government Engineering School in Insein, with satisfactory results. It is only a question of raising the experiments to a real commercial scale. Our present scale is two pupils per year. The young Burman takes readily to handwork, that is to say if you recruit from the right source. If you take the son of a ploughman who has been for generations descended from ploughmen, you cannot expect him to become much of a craftsman. If you take a youth whose surroundings and training have led him to regard life on an office stool as the *summum bonum* of his working existence, then, naturally, you may have to exert considerable effort to induce him to see the greater dignity of intelligent craftsmanship. But if you recruit from the right source you have good material worth training, and in spite of his faults, his human weaknesses, and his lapses from rigid industrial self-discipline, I will say this for the young Burman—he is a very loveable sinner and readily responds to sympathetic instruction.

So much, then, for the Burman craftsman and his industries. For one having a leaning towards education, the educational needs perhaps appear strongest, but in justification of that attitude I would again emphasise the very great change which has come over the country owing to its contact with the West—a change so great and rapid as to leave the natural and uninstructed craftsmen hopelessly behind.

In making suggestions I have, I am aware, put forward what some regard as heretical doctrines. I have advocated vocational education in the schools. Well, I hold that all right education has a vocational function. It is not its only function, but there is a tendency among some theorists to forget that this is a function of education. If the schools fail to leave the youth fitted for some part in the world's work, he must perforce acquire that knowledge after leaving school, and generally he acquires it in a haphazard and therefore uneconomical fashion. It is a question as to when the vocational side of education should have its first emphasis, but that it should be attached to the school training and not left to unguided absorption I have no doubt whatever.

In a very able paper read before this Society a fortnight ago, the author, Mr. Hartog, quotes the oft-repeated remark that Indian education is like a top-heavy pyramid, and he deprecates the suggested remedy that the apex should be lopped off, but advocates rather that we should widen the base. I do not think anyone who cares at all for the educational work now being done in India could fail to agree with him; we cannot, and would not, reduce the height, but it is for the broadening of the base that I stand here. And of course a base has two dimensions. If you widen it as regards the numbers of pupils, you must also widen it as regards the subjects, not by a greater number of subjects for each pupil, but by a wider choice of subject groups. To one whose interests lie, as do mine, in the lower strata of education, this plea for broadening the base has a special appeal. You may train your scientific, your technical, experts of high university degree, but unless you prepare the substrata, the craftsman and all that lie between him and the engineering expert, or the scientific specialist, to what purpose is your higher training? And in this the development of village industries can play an important part. For that work education and organisation are necessary. Owing to the rapid changes in the condition of Burma, the work of organisation cannot be left to simple evolution; the evolution must be quickened by some special

stimulus, by direct effort. It may, it does at times, need all the three graces of faith, imagination, and love to visualise the development of these industries, to view their future with optimism. But their present vitality gives ground for faith; the small measures of success already obtained encourage imagination, and no one who has had anything to do with these industries and the men employed on them can fail to feel some real regard for them.

I set out to show that some handicrafts are desirable, that in some cases the causes which have weakened the industries can be excised and removed by suitable treatment, that certain industries have already been improved by aid which cannot be called mere benevolent bolstering. I have endeavoured to give reasons for my ideas and some indication of the remedies which I regard as necessary. I may have been speaking to those who did not require proof of these things, I have certainly put forward views which are liable to criticism, and the real value of this paper—if it has any at all—will be in the discussion which I hope it will raise.

DISCUSSION.

THE CHAIRMAN (Sir Harvey Adamson) said he was sure all would agree with him that Mr. Morris had given them a most interesting and instructive paper. If he might venture on a word of criticism he would suggest that the title—" Burmese Village Industries "—was somewhat of a misnomer. Take, for example, the silk industry of Amarapura and the lacquer industry of Pagan. These places were small towns, the headquarters of sub-divisions, and were not villages as the term was understood in Burma. Similarly, the centres of activity of gold, silver, bronze, and kindred arts were towns or very large villages. He preferred to call such industries the minor industries of Burma. The industries conducted in the ordinary village, which he might call all-village industries, were in a backward state. In most villages would be found weavers of cotton, all women, a carpenter, blacksmith, some makers of mats, baskets, agricultural implements and cheroots. The weaving was excellent, though the loom was primitive. Other village products—such as oil mills, sugar mills, dahs or knives, boxes, and implements, were very crude. Every man was his own house-builder, the houses being built of bamboo, with a plank flooring and thatched roof. The Burman was a poor carpenter. Most of the industries carried on in the villages were in the same condition as they were hundreds of years ago. He hoped that in any steps taken for the improvement of the industries of Burma, these all-village industries would not be neglected. Speaking generally, it was to this source that they must look for the supplementary industries which were needed so much, especially in Lower Burma, where every villager was a cultivator of rice, which occupied his time for only a portion of the year. Turning from all-village industries to industries in lacquer, silk, gold, silver, and bronze, it was amazing to see such beautiful objects produced by a people who were so backward in their ordinary village industries. Skilled instruction—for which great credit was due to the author of the paper—combined with latent native talent, had enabled the Burman to turn out the most exquisite objects of art, and he advised the audience to pay a visit to the Indian Galleries of the Imperial Institute to inspect the examples which had been brought over to this country by Mr. Morris. Mr. Morris had mentioned the difficulty in finding a market in London for the village wares owing to the impossibility of producing the article required in sufficiently large quantities for the trade buyers. Still, he thought purchasers ought readily to be found for the art productions. Mr. Morris had not attempted to enumerate the industries of Burma. He (the Chairman) would add toy-making as a quantity-production industry. Burmese toys were very quaint and very fascinating to children, and they had the advantage of being cheap. On several occasions he himself had sent over consignments for disposal here for charitable purposes, and they had all been snapped up, even at the high prices fixed for a charity bazaar. He thought it very possible that Burmese toys could be produced in sufficiently large quantities for exportation to this country. The one example at present showing what instruction combined with co-operation could do was afforded by the silk industry of Amarapura, particulars of which were given in the paper. He did not quite share Mr. Morris's views as to the possibilities of sericulture. He thought the workers would still have to rely upon imported silk. Sericulture involved the sacrifice of life, which was contrary to the Buddhist religion, and in Lower Burma—where at one time there were many quite flourishing concerns—those engaged in the work had been ostracised and not allowed to intermarry with other Burmans, so that their lives had been made most unpleasant. This isolation, combined with increased imports of silk yarn, had destroyed the trade, and he doubted very much if it could be revived to any appreciable extent. The silk-weaving industry was up to date, the one example of improvement, but *ex uno disce omnes*. The Burman was very conservative, but he was always ready to follow a good lead, and showed not a little initiative in adopting it. Many instances of this characteristic could be mentioned. Co-operation was one. It was only a few years since the co-operative movement was introduced into Burma. Now there were a good many well-managed co-operative banks and credit societies. Another instance was the army. During the Great War, for the first time Burmese battalions were raised, and he had been informed that in the use of machine-guns, signalling, pioneer, and sapper work they showed general intelligence

far above the ordinary infantry units of India. As a third instance, Mr. Morris had once told him that he had Burmans in his engineering school, who, after a short course of instruction, had beaten the Chinese in the craft in which they excelled—carpentry. In this characteristic of the Burman, supplemented by instruction on the lines suggested by Mr. Morris in his paper, lay the soundest hopes for improving the minor industries of Burma.

MR. C. W. DUNN, I.C.S., late Registrar of Co-operative Societies in Burma, said the author of the paper had been extremely modest with regard to his own contributions towards the improvements in Burmese minor industries. He believed the method of showing the red figures on the black pottery was really invented by Mr. Morris, and that the utilisation of paddy husk as a fuel in the native kilns was also due to his researches. For the past eight years he (the speaker) had been associated with co-operation in Burma. They had no Department of Industries, except so far as Mr. Morris himself supplied this want, and the movement therefore had perhaps not received as much support as it deserved. Work, which in some provinces was performed by Directors of Industries, had to be done by officials serving with the Co-operative Department, but was limited in amount owing to their other duties. With regard to what Sir Harvey Adamson called the "minor industries," silk weaving required a division of labour, centred under one control; in fact it seemed to him to be a factory and not a cottage or home industry. The Government no doubt could help the industries by teaching improved methods. But he thought the Burmese themselves were capable of developing production by organising factories under joint-stock companies or co-operative societies. Indeed, they had started a Co-operative Weaving Society or Company at Amarapura within the last year. The workmen had combined with a certain number of master weavers to form this company, in which the workers did the weaving and the masters undertook the sales of the products and the supply of raw materials. It did not seem to him that this could be called a village industry. He took it that Mr. Morris meant home industries, upon which the people are employed in their own houses or cottages, separately. The cotton industry, as at present carried on in Burma, was to a great extent a home industry. The weaving was done by people who either grew their own cotton or bought yarn for the purpose. The work was done by the villagers' wives and daughters, who sold the cloth to itinerant middlemen. The rough cotton fabrics produced in Northern Burma were readily disposed of in competition with imported goods, because of their superior strength and good wearing qualities. The Government were now proposing to inaugurate temporary local itinerant art schools, with the assistance of the co-operative organisations. The local co-operative society would apply to the department for an itinerant teacher, and raise sufficient funds to erect a temporary school. The Amarapura Weaving School would send a trained teacher to the locality for from three to six months, until the supply of persons requiring instruction was exhausted. The teacher would then move on to another centre. This plan would avoid any excessive centralisation. Generally speaking, Mr. Morris proposed that the Government should intervene and control the sale of the products of these minor or village industries, and presumably undertake the risk of purchasing stocks for which perhaps there might be no market. It seemed to him that that would be a difficult problem for the Government or for the co-operative societies, and he thought the former were wise in acting cautiously. It was really more a matter for the Burmese middlemen, who were acquainted with the wants of their customers. Within the last two or three years there had been considerable development in urban credit societies, which were intended as banks for the middle classes and people of moderate means. These societies were able to finance small traders and manufacturers up to, say, Rs. 10,000. It was extremely difficult for the limited number of Government officials available to discover and develop profitable lines of industry in different parts of the country.

MAJOR A. A. LONGDEN, D.S.O., asked Mr. Morris if he could say how many household arts were thoroughly taught in schools in the Philippines. At the present time the British market was overrun with the work of partially-trained disabled soldiers and sailors which was sold at exhibitions and bazaars, etc., and he was afraid this tended to have a detrimental effect on the disposal of the legitimate work of *bonâ fide* artistic craftsmen.

MR. W. H. EVANS said one difficulty that occurred to him in connection with the paper was the superimposing of Western culture upon an Eastern people in the development of their art and industries. But the paper had shown how improvements had been effected by allowing the conservative native craftsman, with a little pressure, to make progress along his own lines of work. He would like to ask Mr. Morris if he had any information to give respecting Burmese work in semi-precious stones. Recently there had been considerable inquiry in this country regarding such work, owing to the elimination for the time being of the German craftsmen in semi-precious stones, more particularly amber. New sources of supply were being sought for, with, he was afraid, very little result. Germany seemed to be specially endowed by nature with large deposits of amber suitable for the production of high-class ornaments, and he thought possibly alternative supplies might be procurable from Burma. With regard to the difficulty of disposing of the art productions of the Burmese villages, he thought perhaps this to some extent could be overcome by co-operating with kindred Home Arts and Industries Associations in this country, who might be willing to include the Burmese art wares in their sales exhibitions.

Mr. Davidson Keith asked why all the speakers seemed to depend upon the home industries of Burma. He thought such industries were best carried on in factories. Only by working in combination with others could the Burmese be induced to adopt new appliances and improved methods. He also spoke of the advisability of beginning with young people and giving them a good education.

Lord Carmichael, G.C.S.I., G.C.I.E., K.C.M.G., in proposing a vote of thanks to Mr. Morris for his paper, suggested that in seeking an outlet in this country for Burmese wares, it was not necessary to restrict themselves to buyers who would purchase only in thousands. The tendency nowadays was to encourage people to look to the Government for every form of help. Whilst Government aid was useful up to a certain point, and especially in providing banking facilities, private initiative and enterprise were most important in schemes for development. In many parts of India the native industries were undoubtedly being displaced by European manufactures, generally of German origin, and, since he left the country, he believed by Japanese. Personally, he thought many of the German goods very ugly. But the German merchants adapted their productions to the pockets of the poorer people, and gave longer credit. The Germans also attended more to details. The little models of gods which they offered for sale were more accurately made, and generally they paid greater attention to iconology than our own manufacturers did. He did not profess to be a financial expert, and he thought that, as a rule, Government officials were very poor financiers and did not know very much about trade matters.

Mr. Davidson Keith remarked that the Australian Commonwealth and State Governments were doing well in fostering manufactures.

Lord Carmichael said he hoped that was so; but unless things had altered since he left Australia, he thought the Government of Australia were more anxious to develop manufactures on a larger scale than was possible in Burma. Such manufactures as the Australians were encouraging required to be made in large factories, and could not be looked upon as home or village industries.

Mr. D. T. Chadwick, I.C.S., seconded the resolution. Mr. Morris, he said, was an enthusiast in his work, and his paper was very stimulating. It was also timely, coming as it did at a moment when considerable attention was being paid to the desirability of granting facilities through co-operative societies and joint-stock companies for the development of overseas trade.

Colonel C. E. Yate, C.S.I., C.M.G., M.P., in supporting the resolution, said he had never been in Burma, and consequently he could not speak with any knowledge of that country, but there was one thing in which he could sympathise most thoroughly with the author of the paper, and that was in the remarks he had made on the subject of education. He presumed that education in Burma was an offshoot from education in India, and he looked upon the Indian system of education as the worst in the world, and now that Burma had escaped from being drawn into the vortex of the Government of India Bill, he hoped the authorities in Burma would evolve a system of education and handicraft training suited to the needs of the country, and capable of enabling a boy to earn his living in the trade he was best fitted for.

The resolution was carried unanimously.

Mr. Morris, in reply, said that a kindly regard for an amateur effort had reduced adverse criticism. He must confess that he had deceived them; Sir Harvey Adamson said that he had not dealt with the village industries. At the same time the industries with which he had dealt were those with which he meant to deal. He apologised to the gentleman who exclaimed that a ploughman was a craftsman—of course he was; but he had more or less limited his use of the word craftsman in introducing his subject, and under this limitation the ploughman was not included. He only instanced him as an illustration of the advisability of taking into account heredity in selecting recruits for the handicrafts. He did not altogether agree with Mr. Dunn in his ideas on the silk industry. It was a village industry in the past, a cottage industry, and he could not see why it should not continue to be so under the new conditions. To him the possibility of preserving cotton weaving as a cottage industry seemed much more difficult. Sir Harvey said quite rightly that silk-growing was not likely to succeed among Buddhists, but the areas more likely to be suitable, the Shan States, contained large numbers of Christians and Animists, who would have no religious objections to sericulture. Mr. Dunn spoke of the co-operative societies accumulating stocks which would not find a sale. The system of bureaux which he (Mr. Morris) advocated would not be provided by co-operative societies; and while Government might occasionally lose a little on experimental work, they need not, if properly run, incur great risk. The system had anyhow succeeded in the Philippines, and need not fail in Burma. Major Longden asked what were the housekeeping and household arts taught. He was afraid he could give no details; the quotation was from the book mentioned. As regarded the desirability of completing instruction before allowing profitable manufacture, he was giving his own view, and that was the method they had adopted in their craft apprenticeship classes in Insein. Mr. Evans asked about amber. They had supplies of amber in the north of Upper Burma. They had never been developed, and apparently were not large. A

small quantity only came down to Mandalay and was worked into small articles. He described the processes of manufacture of some of the Burmese wares on view at the meeting. In conclusion he said it had been a pleasure to him to speak about the industries of Burma. He believed that a great deal could be done to help them, and that it was well worth while doing it.

LABOUR SCARCITY IN BRITISH GUIANA.

In the discussion on Sir Edward Davson's paper, "Problems of the West Indies" (*Journal*, December 26th, 1919), the Hon. C. Clementi, Colonial Secretary, British Guiana, referred to the injury which that Colony suffers by the smallness of its population. They had, he said, attempted to import labour from the West Indies, but, except in the case of Barbados, none could be spared, and even if the whole population of Barbados was transported to Demerara there would still only be five persons to the square mile. They had to look to countries where the population numbered hundreds of millions, and naturally turned their thoughts to India. Negotiations, he added, had been opened with the Government of India for that purpose. A deputation, representing British Guiana and the West India Committee, was in India when a recent mail left, and it was received by Sir George Barnes (Member of Council in charge of the Department of Industry and Commerce) at Delhi, on December 5th. The principal spokesman of the deputation, the Hon. J. J. Nunan, K.C., LL.D., explained that the scheme contained no trace of the old indentured system, which public opinion in India compelled the authorities there to abolish, and that no contract of any kind would be required. It was proposed to offer free passages and guarantee employment at locally current rates, now about two rupees a day. Free repatriation would be afforded at the option of the individual or family after a short period of years, or at any stage when desired by the supervising officers of the Indian Government. Those immigrants who engaged in agricultural work, either for an employer or on their own behalf, for three years would receive grants of five acres on nominal terms. Additional land could be bought or leased. Regular steamer communication with two classes of passenger accommodation would be provided by the aid of colonial subsidies between Indian ports and British Guiana, and India would incur no expense. As the population was now about 45 per cent. Indian (14,500), and as the constitution involved the political equality of all races, they were really offering India a colony of its own on the north-eastern coast of South America, with fertile soil and a healthier climate than that of India or any large tropical colony. The immediate scheme was limited to 5,000 adults of both sexes per annum for the next three years.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday afternoons, at 4.30 p.m.:—

JANUARY 28.—SIR CECIL HERTSLET, late H.B.M. Consul-General for Belgium, "The Ruin and Restoration of Belgium." EMILE CAMMAERTS will preside.

FEBRUARY 4.—ALFRED E. HAYES, General Secretary, English Language Union, "The English Language and International Trade."

FEBRUARY 11.—LIEUT.-COMMANDER NORMAN WILKINSON, R.N.V.R., O.B.E., R.O.I., R.I., "Naval Camouflage."

FEBRUARY 18.—SIDNEY PRESTON, C.I.E., "English Canals and Inland Waterways." NEVILLE CHAMBERLAIN, M.P., will preside.

FEBRUARY 25.—JAMES CURRIE, C.M.G. Ministry of Labour (Training Department), late Principal, Gordon Memorial College, Khartoum, "Industrial Training."

MARCH 3.—WILLIAM JAMES GARNETT, First Secretary, H.B.M. Diplomatic Service, "Mongolia from the Commercial Point of View."

MARCH 10.—H. M. THORNTON, "Gas in relation to Industry and Housing."

COLONIAL SECTION.

Tuesday afternoons, at 4.30 p.m.:—

FEBRUARY 3.—SIR FRANCIS WATTS, K.C.M.G., D.Sc., Imperial Commissioner of Agriculture for the West Indies, "Tropical Departments of Agriculture, with special reference to the West Indies." LIEUT.-COLONEL SIR DAVID PRAIN, C.M.G., C.I.E., LL.D., F.R.S., Director of the Royal Botanic Gardens, Kew, will preside.

MARCH 2.—G. F. SCOTT ELLIOT, M.A., B.Sc., F.R.G.S., "Trade Routes for the Empire in Africa." COLONEL SIR THOMAS H. HOLDICH, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., will preside.

Dates to be hereafter announced:—

AIR-COMMODORE EDWARD MAITLAND, C.M.G., D.S.O., "The Commercial Future of Airships."

CHARLES H. SHERRILL, "Stained Glass."

LADY INGLEFIELD, President, Buckinghamshire Lace Association (North Bucks and Bedfordshire), "The Hand-made Lace Industry."

GRAILY HEWITT, "Rolls of Honour."

CHARLES CROWTHER, "The Arts and Crafts of Japan" (with examples from the author's private collection).

WILLIAM CRAMP, D.Sc., M.I.E.E., "Pneumatic Convoying Plants, with special reference to the Transport of Grain."

L. GASTER, "Industrial Lighting in its relation to Efficiency."

BRIGADIER-GENERAL LORD MONTAGU OF BEAULIEU, C.S.I., "Roads and Transport in India."

SIR GEORGE CUNNINGHAM BUCHANAN, K.C.I.E., M.Inst.C.E., "The Ports of India: their Administration and Development."

SIR VALENTINE CHIROL, "The Enduring Power of Hinduism." (Sir George Birdwood Memorial Lecture.)

PROFESSOR WILLIAM A. BONE, D.Sc., Ph.D., F.R.S., "Lignite."

INDIAN SECTION.

Thursday afternoons, at 4.30 p.m:—
February 19, March 18, April 15, May 20.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 p.m.:—
February 3, March 2, May 4.

CANTOR LECTURES.

Monday evenings, at 8 p.m.:—

CAPTAIN H. HAMSHAW THOMAS, M.B.E., M.A., F.G.S., Fellow of Downing College, Cambridge, and formerly of the Royal Air Force, "Aircraft Photography in War and Peace." Three Lectures.

Syllabus.

LECTURE II.—JANUARY 26.—The employment of aerial photographs in war—The interpretation of photographs — Types of intelligence furnished—Artillery work — Effects of air photography on strategy.

LECTURE III.—FEBRUARY 2.—The use of aerial photography in exploration and survey in times of peace—Comparison of a photograph with a map—How maps may be compiled or improved—Application to exploration—Things concealed and revealed—Surveys for special purposes—Limitations and future of the method.

CHARLES FREDERICK CROSS, B.Sc., F.R.S., F.C.S., "Recent Research in Cellulose Industry." Three Lectures.
February 16, 23, March 1.

WALTER ROSENHAIN, B.A., D.Sc., F.R.S., Superintendent, Department of Metallurgy and Metallurgical Chemistry, National Physical Laboratory, "Aluminium and its Alloys." Three Lectures.
April 12, 19, 26.

ARTHUR THOMAS BOLTON, F.R.I.B.A., F.S.A., Curator, Soane Museum, "The Decoration and Architecture of Robert Adam and Sir John Soane, 1758–1837." Three Lectures.
May 3, 10, 17.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JANUARY 26...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Captain H. H. Thomas, "Aircraft Photography in War and Peace." (Lecture II.)

TUESDAY, JANUARY 27...Illuminating Engineering Society at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. W. C. Martin, "Colour Matching by Natural and Artificial Light."

Royal Dublin Society, Leinster House, Dublin, 4.15 p.m. 1. Professor J. Wilson, "The Application of the Food-Unit Method to the Fattening of Cattle." 2. Professor H. H. Dixon and Mr. H. H. Poole, "Photosynthesis and the Electronic Theory."

Royal Institution, Albemarle-street, W., 3 p.m. Professor G. Elliot Smith, "The Evolution of Man and the Early History of Civilisation." (Lecture I.

Civil Engineers, Institution of, Great George-street, S.W., 5.30 p.m. Discussion on following papers:— 1. Mr. J. Mitchell, "Whitby Harbour Improvement." 2. Mr. R. F. Hindmarsh, "The Design of Harbours and Breakwaters with a View to the Reduction of Wave-Action within Them." 3. Mr. J. W. Sandeman, "Wave-Action in Harbour Areas: with Special Reference to Works for Reducing it at Blyth and Whitby Harbours." 4. Mr. W. Simpson, "The Improvement of the Entrance to Sunderland Harbour, with Reference to the Reduction of Wave-Action."

NOTICES.

NEXT WEEK.

MONDAY, FEBRUARY 2nd, at 8 p.m. (Cantor Lecture.) CAPTAIN H. HAMSHAW THOMAS, M.B.E., M.A., F.G.S., Fellow of Downing College, Cambridge, and formerly of the Royal Air Force, "Aircraft Photography in War and Peace." (Lecture III.)

TUESDAY, FEBRUARY 3rd, at 4.30 p.m. (Colonial Section.) SIR FRANCIS WATTS, K.C.M.G., D.Sc., Imperial Commissioner of Agriculture for the West Indies, "Tropical Departments of Agriculture, with special reference to the West Indies." LIEUT.-COLONEL SIR DAVID PRAIN, C.M.G., C.I.E., LL.D., F.R.S., Director of the Royal Botanic Gardens, Kew, will preside.

WEDNESDAY, FEBRUARY 4th, at 4.30 p.m. (Ordinary Meeting.) ALFRED E. HAYES, General Secretary, English Language Union, "The English Language and International Trade." SIR EDWARD W. BRABROOK, C.B., will preside.

Further particulars of the Society's meetings will be found at the end of this number.

CANTOR LECTURE.

On Monday evening, January 26th, LIEUT.-COLONEL ALLAN J. C. CUNNINGHAM in the chair, CAPTAIN H. HAMSHAW THOMAS, M.B.E., M.A., F.G.S., Fellow of Downing College, Cambridge, delivered the second lecture of his course on "Aircraft Photography in War and Peace."

The lectures will be published in the *Journal* during the summer recess.

SEVENTH ORDINARY MEETING.

WEDNESDAY, JANUARY 28th, 1920; MONSIEUR EMILE CAMMAERTS in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Cameron, Alexander, Sunderland.
Campbell, Archibald Jack, Dalmuir, Scotland.
Subedar, Ardeshir Rustumji, Bombay, India.

The following candidates were balloted for and duly elected Fellows of the Society:—

Barnes, Jabez, J.P., Harrow.
Haigh, Bernard Marker, M.B.E., D.Sc., London.
Hammer, K. V., Christiania, Norway.
Horsnell, Daniel Thomas, M.I.Mech.E., M.I.Mar.E., London.
Howard, Henry Eliot, J.P., Stourport.
Jack, Robert Wilson, Girvan, N.B.
Kemp, Mrs. Mabel Amy, London.
Longstaff, Captain George William, R.A.F., London.
Mitchell, Harold F., London.
Mukharji, J., Srinagar, India.
Ogden, Alfred, Manchester.
Oldfield, Percy Jack, London.
Parsons, Robert Hodson, Assoc.M.Inst.C.E., Chingford.
Scott, James P., Birmingham.
Stuart, George Archibald Douglas, Bournemouth.
Tidswell, Mrs. Mary Florence, London.

PROCEEDINGS OF THE SOCIETY.

SIXTH ORDINARY MEETING.

WEDNESDAY, JANUARY 21st, 1920; The Right HON. EARL FERRERS in the chair.

The paper read was—

ANCIENT COTTAGES AND MODERN REQUIREMENTS.

By ALFRED H. POWELL.

Of the many calls upon us for increased production, perhaps the most serious one is for houses. Much of this work will be the building of new houses and much will be the making good of our old ones. It is in the hope that I may be able to say something to help this making good—to prevent, it may be, unintentional making bad, that I have ventured to accept the Council's invitation to read a paper here. I will say a word to begin with in explanation of my title. I quite realise the necessity of adapting and refitting old cottages to modern use, but I feel it must be one of our

first aims to look to the buildings themselves as part of an even larger question than this present one of accommodation. For a great many of them are of such a kind that their demolition or mishandling would be a serious national loss. We shall therefore, I think, agree that architectural character, history and quality of workmanship should be to a great extent our guide in adapting ancient cottages to modern requirements. The more we look into it the more ready I think we shall be to feel that often a considerable sacrifice of material convenience may be not only advisable, but an obvious piece of common sense, and I ask you not to think me intolerant of many modern inventions and comforts if I emphasise rather the qualities and characteristics belonging to ancient buildings.

I am going to try, then, to tell you what I feel about their claims upon us as an ancient inheritance—to show in some degree how they were built; and finally, if there is time, to say something of their past and present occupants, for I think we can hardly come to appreciate the buildings without some consideration of their time-honoured use.

One thing appears very clearly at the outset, that, whereas the new houses will be just new houses, the old ones have for many generations been *homes*. However well, however thoughtfully we architects go to our work of housing, however nicely planned and outsided the new houses may be, they cannot all at once become homes. It takes long association and use to make a house into a home, and age, which is the reward of wise building, is the perfection of architecture.

There is, perhaps, no country in the world that can show in so small a space as England so great a proportion of ancient cottages, well built and beautifully gardened, and still in wonderful working order. They are our peculiar inheritance, and we are not alone in looking upon them as the chief beauty of these islands. Not only our own kith and kin, but strangers from overseas have come to look on them as in great degree the very gist of English country; and we have a duty, it seems to me, laid on us as English to safeguard these buildings, remembering not only ourselves, but those also who at times come from the colonies to seek out, among English hills and meadows, their own old family homes. We who live with them always and see them daily may easily come to take them as a matter of course. Like the stars in the sky, for us they have "always been there"—a part of the landscape—but so much an integral part of England that without them it would be no more the England we know and would cherish. Often during these years of the war I have thought of soldiers and sailors scattered over the world in all kinds of difficulty and danger, and felt how strongly must the thought of these ancient homes have upheld the courage and steadied the faith of thousands by no other means than by just being there in their old places. Certainly, too, those of us who stayed in England, consciously or unconsciously, have owed much to these embodiments of an older life during this time of strange confusion and unsightliness.

Another point we may bear in mind in considering the possible fate of old cottages is that our modern architecture, in spite of all the pains we architects take, is not a popular art with a real message to the people, and the host of new buildings in all our renewed towns and cities practically passes without notice or comment: they are buildings innocent of power to move our hearts—they have little food for the spirit. But with ancient buildings it is not so, and I do not think this is entirely due to their being ancient. Few have not felt the glow of pleasure that any old English village can commonly evoke, while the more celebrated greater works, the mediæval abbeys, the castle, and the churches, make constant appeal to our intelligence and affection.

The deeper reason for this is no doubt unrecognised in a general way, but whereas new work of our own time is bound to be the result of individual effort in a sophisticated age, ancient and mediæval building was democratic in the sense that it was a folk-speech. The common energy of men ran to fine building and the arts, and these became under their hands a language very widely understood by the whole people. And though I have no wish to touch politics, I cannot refrain from asking if it may not be this that is at the root of our present labour distress? From our work there has departed something that we recognise as present in the work of the old builders. We see that their work was able to give them a life within their life, a poetic edge upon all effort. In a word, work appealed to them because it tapped the springs of invention and conscious enjoyment, so that through all their continual struggle for social recognition they kept on making things that still fill us with a pleased wonder. In their buildings, as Professor Lethaby tells us, there was magic even to their makers. I am con-

vinced that by workmanlike consideration of old work, by close looking at the actual substance and form of it—not as critics, still less as imitators, but as interested to the point of doing it, in all work well done—we might learn a new ideal of work and see it as the rational and sufficient outlet for all human activity. I will risk your smiles by telling you that I do not remember a greater pleasure than once sitting in the full sunlight of a summer afternoon astride the ridge of a roof I had in good part built with my own hands, and wishing more of us could have a similar point of view and feel what I felt just then about golf and cricket. I want to keep my paper within its proper limits, but I find it very difficult to refuse the by-products of it or to look upon building as a professional housing expert would, and as perhaps I ought to try to. I want something more than the visible attributes of ancient cottages, though I find that sufficiently unnoticed. I feel that they bear a message, that there is indeed a gospel of ancient buildings that we cannot rightly decipher from the visible structure alone, but must see through that something of the life that created it. In these buildings, so unlike our own, there is closely wrapped up—it cannot but be so—vital truth about life on these islands, and every time we look at them we become insensibly touched by their deep significance for us, and in a thousand ways held together as a nation by their familiar presence.

So, in a way, the tables are turned upon us, and it becomes more "our" requirements that are the introduction to their proper treatment. And though for myself I do not lay claim to any special knowledge of the hidden lore of building, I do think I see that by the study of it and its long history a new insight into work may be possible, an insight likely to reward us, not only through added knowledge, but through the light it will throw upon modern work problems.

All the arts are sprung of use, and are thereby the most direct guides to the long story of the use of houses. We know how slowly customs die and how primitive habits and beliefs endure, and there are buildings at our doors that if properly seen and examined would throw light on these things. The worship of fire is not wholly dead, the significance of the square and the circle, the feeling for position, for true orientation, the imaging of the heavens, and the earth and sea, have all their part in us, and have all found expression in building. Who shall say what may not be the genealogy of our foundation-stones, of thatchers' knops, of vanes, of even square houses? These things hide about us still, and search and discovery are broadening the interest of life. There was a house in Sussex, I remember, to be surveyed for alteration. At first sight it was the ordinary Sussex type. But its roof was large and wide and its walls were of oak and wattle. Examination of the roof brought it at once within the range of origins. The timbers were thickly coated with soot. Gradually its history was sifted out from the modern tenements that encumbered its ancient plan. A central hearth, a large hall with an open roof, screens and offices, all came into their places once the roof had given the clue.

And but yesterday I was in a cottage in Suffolk, built, I suppose, about 1350, where a further step in the story of the hearth was illustrated. The whole end of the house was given up to the fire and its smoke, making a chimney some 15 ft. by 6 ft. of timber and plaster, the hood shrouding the fire and rising in great framed panels of oak and wattled clay through the finely carpentered roof to the ridge, some 30 ft. from the ground.

A book lately published on old methods in building, by Mr. Innocent, is full of interesting details of his research into these things. The book is written with the idea of being helpful now, quite as much as for its explanation of unsuspected origins and primitive building. It cannot be doubted that there are many cottages and other humble buildings still standing whose antiquity is far greater than is commonly supposed, and I would like to see a serious attempt made to examine and schedule all the earlier *little* buildings of England with a view to their proper treatment and preservation. For our present purpose, however, I would call any serious building put up before 1700 an ancient building. As to defining a cottage I find little help in the dictionaries, but if I were asked for a definition I think I would call it a building whose main purpose was to be convenient for workers and work—so small as to be in constant touch with the out-of-door world and the elements—by no means a place to be idle or ill in.

And with all the disadvantages we may conceive of in such dwellings, there can be little doubt that to that close touch between indoors and out, to that absence of domestic comfort, is owing the preservation of national hardihood; while we must remember that it is from these

old homes of England that has come a race of workers who have borne for some 600 years the burden of England's greatness, finishing patiently and perfectly the work they understood, and without which no nation could exist.

Take this account from Richard Jefferies of one of these workers:—

"A tall, big man, every inch of his frame had been slowly welded together by this ceaseless work —continual life in the open air and coarse, hard food. This is what makes a man hardy. This is what makes a man able to stand almost anything, and gives a power of endurance that can never be attained by any amount of gymnastic training.

"His food was dry bread for the most part and a little lard.

"I used to watch him mowing, with amazement. Sometimes he would begin at half-past two in the morning and continue till night, taking only a short rest on some dried herbage under a tree at midday."

In thinking of the outdoor workers' attitude towards a cottage of this kind, I always call to mind the words of an old carter I once knew in Surrey. We were talking about two old men, well known in all that county (one was called "Uncle" and the other "Teapot"—I never heard any other name for them), men whom we should call tramps, but whom I always found ready to be helpful if wanted. I asked him where they lived, for I had seen them at tea in a neighbouring ditch that afternoon with a kind of tent thrown over the hedge to protect their fire. He answered, "Oh, they never use no houses, you know." Before that I had never thought of a house as a small object to "use," and I felt the precarious nature of a cottager's life in a new way.

Most old houses had no foundations, and none of them any damp course. They were put straight upon the clean earth. I like to think of great buildings and cathedrals in that way—built on clean and sweet soil with no complications of underground pipes and heating apparatus. Do you remember the tale of the Epping Forest gipsy? His life was at its ebb, but he could not make the change inside the caravan amidst all its needless humanities. "Put me out on the turf," he said, and they laid him on the fresh green grass, and he died—took fresh breath for new adventures. In men and buildings there is the same ineradicable tendency and influence to fetch back to origins. It is there we can die and revive rationally with better powers for better work. And we English are not come of thralls or the worthless, but were born of a fearless and hardy folk, and it is surely our great privilege that we may still, if we will, read the very handwriting of their strength and hardihood. In the work they left us we can truly see what kind of a folk they were, and now after that early edge of life has got somewhat dulled, learn a little of their wisdom and outlook upon land that had as yet seen nothing of coal smoke or machinery.

As to the present condition and standards of comfort or discomfort we find to-day in ancient cottages we must in our judgment of them be careful to be just.

Professor Geddes once showed me a plan—a regional survey of Salisbury—which made it clear that the mediæval town had been set out on broad and sensible lines with quadrangles of houses, straight streets, and square "places"—a city with abundant gardens and fresh air. This plan and early thoughtfulness for the health and service of the people has been (mostly during the last 150 years) completely overridden by allowing thoughtless, or perhaps too thoughtful, persons to fill up the old spaces and gardens with rent-paying tenements that very quickly degenerated into slum areas; the point being that the mediæval plan was a healthy and sensible one and we spoilt it. Similarly, after the open galleries and staircases that abounded in the backs of old Edinburgh houses had been closed in by order of the medical officers, a great increase in serious illness was noticed. The enforced work in the open air, the domestic discomfort as we find it, tended to healthy life.

Our ancient cottages and farm-houses were seldom more than one room thick—strongly built but primitive dwellings—built for use rather than enjoyment, for shelter from the worst of the weather, and only gradually becoming the homes of men and women to whom life and work were *one thing* and the house, at first, only a convenience for carrying on that work.

The development of these old cottages, by what we will call supplementary modern requirements added from time to time, has in most cases obscured the original form and arrangement—which was, generally speaking, simple and spacious and peculiarly fitted for its purpose. This development has been allowed to go on in a haphazard way until we often find cottages that once had ample room and great manners divided and sub-divided into inconvenient little places with dark corners and stuffy chambers, making the mere labour involved in keeping up a moderate standard of cleanliness more than any busy woman has the heart to

face. The so-called progress of civilisation, acting upon imitative ignorance, has encouraged this complication, this spoiling of a good original, and made opportunities for illness and brought about many unnecessary problems.

The first modern requirement with regard to ancient cottages seems to me therefore to be education, both for the users of them and for ourselves. For them that they come to see a better form for their own lives; for us, well, not much more than that we help them by removing some of their difficulties. This may well include a general tidying up of the old dwelling-place, but it ought also to enable us to see that they are manifestations of a great period of English building and craftsmanship. The ignorance and apathy of authority with regard to them is a serious matter, and from this side their greatest danger. In its present unorganised state neither study of history nor expert knowledge of building has weight against the word of any medical officer whose entirely honest judgment is often as entirely a mistaken one.

Of the proper treatment of old cottages with a view to their re-use under improved conditions, it is only possible to speak generally. The particular construction and condition of each house must suggest the treatment desirable. No old cottage need be condemned to destruction that has its outer shell still in fair condition. It will be cheaper to mend it and re-cast the interior than to build a new one. The first thing to do is to get it examined thoroughly, to find out the cause of its disorder—and there is a very widespread disorder that is common to all and has been the chief cause of dilapidation, illness and expense, and that is the inefficient disposal of rain-water from the roofs, and the consequent soakage of the ground. We have seen that most cottages, and indeed most ancient buildings, have no foundations and no damp-proof courses, and though originally perhaps that was no disability, yet surface soakage will let down any wall in time by softening the once firm ground, and the slow disintegration of the lower parts of the wall. Foundations and damp courses are I think both much over-rated, and could in a great many cases be safely dispensed with, provided proper attention is given to surface drainage. In many stone-built houses—for example, in Rutland, Northamptonshire, Gloucestershire, and Wiltshire—the stones were bedded in the ordinary soil of the district, and not intended to resist this continual soakage, as is often seen by the sheathing of the wall bases with large flat stones, and by the rough stone drainage which is a common plan with Gloucestershire builders. A damp course in such buildings merely serves to retain accidental moisture. These points, in a stone or brick building, should be the first seen to, indeed, it ought to be the common practice of all owners of cottages to have this vital work kept regularly in order. This might lead some day to rain-water storage tanks.

In timber buildings the usual plan was to lay balks of oak along the ground for a foundation, sometimes on mason or brick work, sometimes not, and these, of course, are greatly damaged by continued neglect of the surface drainage. But here again the remedy is a simple one, and if the foundation timbers are past work new ones should be inserted to take the uprights as before. I daresay many of you have noticed, in Surrey and Sussex cottages, a wedge-shaped cut some six or seven feet from the ground, in the vertical timbers of the wall frame. These were made to take shoring pieces, and I know a man who had often used this method of holding up the framing while a new footing to the wall was being inserted. That is part of the common tradition of timber house building in the South of England. When a stone or brick building has become cast, or out of the upright, it has often been found a simple matter to push it into the vertical again with shores and wedges. If it is a timber building that has gone over, it will generally be enough to strengthen the joints in all the vital parts of its construction with iron straps. The chances are that it will have taken its new bearings, and any attempt to restore its verticality will be hurtful. Having made sure of the walls in this way quite half the problem of repair is solved. The next most important step is to get the roof right. The rest can then follow at your leisure. In certain cases mortices may be lengthened to allow non-uprights to be moved along in them —repinned—and the old mortice filled in. In examining oak roofs, or in some cases roofs of fir, the timbers will be perished on the surface and quite sound otherwise and in no need of renewal. I have seen old roofs pulled down whose timbers would have lasted another 100 years at least if kept dry. Supposing the bedrooms are too low—and there are possibilities in low rooms that at first sight may appear untenantable—if rooms are too low it is often quite easy to raise the entire roof without removing a rafter, by

jacking it up slowly with a number of jacks placed so as to take the weight at the constructional points. For this purpose it is only necessary to have raking shores, loose at the bottom end and attached to the wall-plate, so that with each screwing of the jacks the shores also rise and can be wedged, thus avoiding any risk of collapse. If the lower rooms are too low, the small timbers of the floor can be cut off at the wall face, a slot made in the wall to let the main beam move upwards, and beam and floor raised together. Then fill in your walling below the two ends of the beam and lay a wall-piece across to take the ends of the shortened joists.

For damp floors of earth or stone the remedy depends on the kind of new floor to be used. Solid floors are best made dry by a thick layer of dry, broken rubbish covered with 2 or 3 in. of cement concrete; even a running stream will then not affect the finished surface, which may be of boards laid solid in mastic, or of tiles or stone laid in cement or sand.

Generally speaking, all by-laws should be got out of the way in favour of local common-sense, and then difficulties can become interesting, and their solution easy and entertaining. In all such work an old building deserves to be treated with all available respect, such as the use of oak to repair an oak frame—or an oak floor—the use of stone lintels in a stone house rather than concrete, and so on.

Another point in which we can do honour to an ancient building is a more difficult one to come by, and that is to see that the work done in repairing is well finished. We find workmen now cannot understand true finish. A bad piece of work well sand-papered or puttied up is for them "finished," except in rare cases in the more out of the way parts of the country where good habits still prevail—whereas true finish is just true finish. It has long been a joke against stonemasons—a joke only understood by architects and not by all of them—that stonework is only finished after it has been dragged to a perfectly smooth surface, and if asked to finish otherwise, viz., with a boasting chisel, they will spoil that surface afterwards to suit the taste of those who wish it so left from the chisel. Both, in their proper places, can be true finish, but not both at once; and while the finest surface may be desirable on a door-jamb or chimney opening it is obviously unnecessary on a tower or external walling. For the rest of our repaired cottage we have windows and doors to see to and plastered walls and ceilings. Many windows seem too small that become large enough when made to open; in bedrooms it is generally an easy matter to add dormers or heighten tiny windows without any damage to the proportions of the house—but it must be done from the house's point of view and not a mere cold insertion of a ready-made window. Downstair windows where the rooms are seven feet high can be safely taken up to within a few inches of the ceiling.

Where a cottage possesses any remarkable feature, such as a mediæval window frame, with stone or wooden moulded mullions, it is better to introduce a new window altogether and leave the old alone after due mending.

For new out-buildings, use local materials and if possible local workmen, weather boards, cob, rough walling, thatch or tiles as in the main house; but the work should be done well, well planned and well finished, for it is in the completeness of ancient work that so much of its character lies. We are too apt to slur over our building work, to "fling houses together," as some have dubbed it, a practice that greatly impoverishes the English landscape—makes it look thin and weak.

It is not enough to accept wages. We need more, as an American has told us, to accept the challenge of life to reveal our full powers and to desire opportunity to make the proof. Still there are those yet living who have not abandoned the better way; slowly and with protest they are forced to give up what they know to be right, yet holding in their hands the accumulated traditions of all great handiwork. The mere enumeration for example of the things known to a farm labourer would put to shame, in its comparative effectiveness, much of our higher education. To him we owe the well agriculturalised country side, the hedging and ditching, the cleanings and burnings, the furrowing of the land, the placing of ricks and their building. He knows the times for all these things and they are familiar to him. Or take the woodmen and their various knowledge, or the wheelwrights, the hurdle makers, the thatchers, we accept all these; not greatly caring if they persist or cease, and taking little thought for their decent housing.

And yet you cannot work with these people without finding in them unexpected wisdom of all kinds, but especially work wisdom—all the first steps as well as the matured knowledge seem fresh and new, and their readiness to impart it is only hindered by the awkwardness

of speech. One will tell you the proper wood to use for an axe handle, another will tell you how to sharpen and set a saw so that a needle can run along the teeth of it, how to test the steel of it by making it sing as he strikes it with his finger tips.

My plea for ancient cottages is bound up with the thought that they are the places where England was made, the homes of all country handicrafts the explanation and the history of the people, an object lesson for our own time in simplicity of life and straightforward building that has been the basis of England and English life through so many centuries. It is surely no small part of English history that here in these humble dwellings has grown up the knowledge of all agriculture and all building. No one can say from what remote antiquity this knowledge came, but we need to remember that it was only serviceable to workers, in their doing of work, only indeed comprehensible to them as rules of work.

DISCUSSION.

THE CHAIRMAN (The Right Hon. Earl Ferrers) said the paper had been a most stimulating one on the human side of old buildings, and probably a good many of those present very much enjoyed having the subject presented to them in words which few could have chosen as well as the author, because he really did fundamentally sympathise with old country life and its traditions, of which ancient cottages were a visible sign. Besides being that, they were in a way a crystallisation of an old type of life through which one could read a bountiful amount of the past with sympathy. At the present time history was very much valued, and our modern idea of history was a history of people and not merely a history of dates and battles and kings, or even of constitutional movements. Our interest in history was fundamentally from the point of view of the people and the community, just as our interest in art was centred in the school of painting rather than in the individual artist. Therefore the present was certainly not the time to throw away the whole of the extraordinarily interesting and charming evidence we possessed on the fascinating subject of the life of our forefathers.

MR. BERNARD SHAW said that it must strike Mr. Powell as very odd that when he, skilled as he was not only in building but in all the domestic crafts associated with building, had told the audience all he knew on this highly technical subject, the first invitation to speak should be addressed to a literary man who obviously knew nothing whatever about them. He was not sure that a great deal of mischief had not been done within his own lifetime by building which was purely literary and nothing else. He had lived in some literary buildings, and had felt intensely relieved to go back to an eighteenth century house, a sensible sort of house made by simply putting a number of rooms together and making a passage by which to enter them. The literary and artistic house—a place where everything was made as dark as possible, where there were as few windows as possible, and as much of those windows as possible was filled up with lead—in which one lived with an exalted sense of its artistic qualities, was really a sort of architectural hell.' He had come to the conclusion that what is wanted is a law that every building in this country shall be knocked down at the end of twenty years and a new one erected in its place. Of course that would get rid of the old cottages; but what right had the people of this country to possess old cottages? One of the reasons why so much of our building work was bad was that we had got into the habit of sponging on the past. People made a tremendous fuss during the war about the destruction of cathedrals, such as Rheims Cathedral; but in a competent state of the arts and crafts the sensible thing would be to get a new cathedral and new stained glass, and do the whole thing over again, and see if it could not be done better. If we were a genuinely active people, producing decent habitations and decent art, it would be very hard for an old building to keep alive. An architect in the fourteenth or fifteenth century regarded a Norman cathedral simply as a building out of which he could hew something perfectly new. Personally, he had all his life had the feeling that every generation ought to be able to produce its own art, and that the worship of the past that people of the present day had been driven into was a diseas that could be cured only by the wholesale destruction of all the monuments of the past, so as to force us by a kind of starvation to produce our own art. People tolerated ugly buildings and ugly surroundings, and then during their holidays went to look at a beautiful old house as something unique. It was certainly pleasant to look at some old English villages and cottages; but what a horrible thing it was that a pretty cottage or village should be a spectacle which people travelled a long distance to see! It ought to be a matter of course, so that no single person in the country should look twice at a decent cottage. If the wholesale destruction of human beings involved by a war could be avoided, he would be glad to have half a dozen wars, so that all old buildings could be destroyed and replaced by new and perhaps better ones.

MR. H. H. STATHAM, F.R.I.B.A., said he had listened to the paper with great pleasure, and he thought one very important point made by the author was that the old cottages he described were not only buildings but homes. He did not agree with the author about the unimportance of foundations. Mr. Powell liked to see the stone work put on the clean earth. That was done with the front of Peterborough Cathedral, and the result

was that enormous expense had to be incurred to straighten it again. He thought the smallest cottage would be better for a good foundation which could be trusted not to give way.

The Author, interposing, said he believed the foundations of Peterborough Cathedral were about ten feet deep, being placed on faggots on the marsh, and proved inadequate only because the marsh was drained.

Mr. Statham, continuing, said that he thought mediæval builders did not trouble themselves very much about foundations. A great many old cottages had very small windows, which looked very pretty but which were unhygienic, and in the garden cities at Letchworth and Hampstead the houses were also built with very small windows, simply because the ancient cottages had them. He thought that was a great mistake. Then again, ancient cottages had very high roofs, which looked very picturesque, but they were built in that way chiefly because mediæval carpenters had not acquired dexterity in building low-pitched roofs. In these days of concrete he did not know why pitched roofs should be built at all. They need only be steep enough just to throw off the water. People thought that flat roofs were not picturesque, but if one looked at a photograph of an Eastern town it would be seen that all the roofs were flat and yet the place looked picturesque. It was only a matter of association. The old cottages were very deficient in any provision for cleanliness. One of the things people were being encouraged to do now was to have some corner in the cottage where they could put a bath, but that was never thought of in the Middle Ages. With reference to the remarks that had been made about the academic and uninteresting character of modern architecture, he thought that could be got over if people who built cottages would not try to imitate the old ones but would simply consider how they could produce the most convenient and the most lasting building with the materials which were most in use at the present day. Cottages would then be built which would have quite a different character from the old ones, but would have a character of their own, and in time people would become as fond of them as they were now of the ancient cottages.

Mr. Maurice B. Adams, F.R.I.B.A., thought the meeting owed a deep debt of gratitude to the author for the tender way in which he had dealt with the subject. The aspect of the matter put forward by Mr. Shaw was impossible if a satisfactory solution of the problem was to be attained. The delightful way in which Mr. Shaw destroyed everything that he approached was quite startling, but, although underneath it all there was a great deal of stern sense and appropriateness, the object of the paper was surely to ascertain as nearly as possible how the delightful old buildings existing in the country could be utilised to assist in solving the problem of housing the people, and how they could be preserved also on account of their historical character and their artistic merits. He did not think Mr. Shaw would really like to see the delightful old cottages and wayside dwellings in this country pulled down. The business of architects was to deal most tenderly with them, and to prevent the local surveyors and local district councils destroying their artistic features in an attempt to make them habitable. With reference to Mr. Statham's remarks about the advisability of building houses with flat roofs, it must be remembered that the climate of England was very different from that of the East, and the old houses in this country had steep rooofs to protect them from the rain. There was no doubt that in building new houses the roof must be considered from an entirely different standpoint from that adopted by the old builders; there must be no wasted space inside the building caused by steep roofs, but he hoped that flat ones would not be adopted. The logical thing to do was to build a concrete house in the form of an ellipse and utilise every cubic foot that was enclosed. That would be a radical enough innovation to please Mr. Shaw, because there were no houses built on that plan, at any rate in this country, and there were very few elliptical buildings in the world, because they could not be constructed in masonry but must be monolithic structures. The principle was the same as that of the construction of an egg. An egg was so strong that it could not be crushed in the hand except by the exercise of a great deal of pressure. But whether the new houses were built of concrete or wood or anything else, the old houses which existed at the present time had to be considered, and if the Royal Society of Arts and the Society for the Protection of Ancient Buildings, and everybody else who had any regard for the beauty and value of ancient cottages, would use their influence and show how those buildings could be made habitable and healthy to live in, so much the better. In the last ten years he had noticed in the press and elsewhere a much more intelligent view being taken of the value of old houses, and he thought also that the public were beginning to realise the commercial value of a good piece of architecture. Until a few years ago that was an idea that had never struck anybody. Those who took an interest in ancient buildings had a duty to perform to the public at the present time, and also, as the author pointed out, to those who were to come. The buildings ought to be preserved for those who were to come as much as for those living to-day, and he thought the paper would very materially help in that direction. He had hoped that the author would exhibit some lantern-slides showing some old buildings in process of being dealt with. It was, of course, a very risky thing to lift the roof of an old building. It was true that in Stuart times and in times previous to that the roofs were extremely low. In some old Stuart cottages in Sussex that he had had to deal with the only thing he could do was to lower the floors. But so long as the rooms

were eight foot high he thought that was quite sufficient. In Victorian days twelve foot was considered the proper height for a room in a villa, but if one could stand upright with comfort in a room he did not think its height was of very much importance. The Ministry of Health had put forward a most admirable schedule of heights of rooms, cubical contents, size of windows, and so on, but they had come down from that to approve of some of the worst plans for building houses that could possibly be conceived. He had seen some plans published recently which contravened every rule that the Ministry of Health had laid down as a guide to new buildings, and yet it was said that those plans had received the approval of the Ministry of Health. In conclusion he wished to emphasise the point that whatever was done to ancient buildings they should always be treated in the most tender and loving way.

MR. A. R. POWYS (Secretary of the Society for the Protection of Ancient Buildings) wished to thank the author very much for his interesting paper, which he had listened to with great pleasure. He thought the practical question to be considered now was what was going to be done to keep the old cottages that were so much appreciated at the present day. They could be made use of by being adapted inside, possibly by having their floors lowered, as had been suggested. He thought, however, that many rooms would be sufficiently high at 7 ft. 6 in. One of the reasons for having a low room was that it could be more conveniently warmed. In some places the inhabitants of the cottages had considerable difficulty in obtaining fuel, and, therefore, low rooms, provided they were sufficiently high to stand up in, were an advantage. The reason why cottages were becoming so dilapidated at the present time was first the neglect from which they had suffered before the war, and, secondly, the very much accentuated neglect from which they had suffered during the war. He did not think new houses would be built sufficiently fast for the old ones to become entirely superfluous at present, but as the new houses were being built the old ones were not receiving the attention they deserved, and by the time the new ones were finished the old ones would be in such a state that it would be very much more expensive and difficult to repair them than it was now. It was necessary to impress upon people that it was as important to repair the old cottages as it was to build new ones, and more economical at the present time. A great many mistakes were commonly made in the process of repair, and it was the object of the Society for the Protection of Ancient Buildings to try to help people to do the work in the right way and to show them the lines on which they should carry out the repairs. His Society had published a pamphlet on the repair of cottages, but they had not yet had a concrete case. At the present time, however, they knew of a cottage in a dilapidated condition which they could purchase for the very small sum of £20, and they wished to buy that cottage and repair it. The cost of repairing it and making it suitable for modern conditions would be from £200 to £300 or £325, which was really a very small sum to collect. They then proposed to use the cottage as a sample and produce another pamphlet with photographs of the work going on, and they would then distribute the pamphlets broadcast throughout the country as a guide to district councils. He wanted to say a word in favour of district councils, which were at the present time in an extraordinarily difficult position. Many of their surveyors had not been trained to appreciate the craftsmanship and the great value of early buildings. Many people understood to a certain extent the value of old furniture and pictures, because they could collect them in their houses, but they did not appreciate the value of ancient buildings simply because they could not collect them. He thought district councils were willing and anxious to do the work in the right way and did not want to be obstructive. All their officials that he had met expressed themselves as most anxious to preserve and make use of old cottages, but it appeared they did not know exactly how it should be done, and the Society for the Protection of Ancient Buildings wanted to show them how to carry out the work. He therefore asked those present to send subscriptions to the Society so that a concrete example could be furnished. He added that his society was willing to give lectures on the subject throughout the country, and that these lectures would be far more valuable were they to include a series of lantern-slides showing the work in progress.

MR. HALSEY RICARDO, F.R.I.B.A., said he would like to ask Mr. Bernard Shaw how far he would carry his destructive process throughout the arts, and whether he would destroy literature and poetry as well as buildings. As a matter of fact we were saturated with the past, and he did not think Mr. Shaw's remarks expressed his real feelings on the subject. With reference to the cottage which Mr. Powys said he could buy for £20, and which would cost about £200 or £300 to repair, if the proposition was only viewed from a commercial standpoint it ought to appeal to everyone, as a cottage could not be built at the present time under £800. He hoped that the synthetic way of planning houses in quadrangles, mentioned by the author, might be revived. There was probably a much stronger communal feeling now than there was before the war, and he trusted that feeling would grow, and that people would realise that their strength did not lie in individualism, but that they were the cells of the body politic, and it was their duty to co-operate with one another. The scattered habitations in villages were one of the causes of the dulness of life in rural districts, and on hygienic grounds there might with advantage be more grouping of cottages. If they were built in quadrangles fairly near together it would be a simple matter to have communal washhouses, heating, and lighting. A

proper system of lighting was very much needed in villages, the darkness of which at the present time was very trying to men and women who had finished their work by sundown. He thought there was a great deal to be done in the way of education. The cottage of the present day was a much more scientific affair than the cottage of the past, and people should be instructed as to how to use it. The children in the schools should be taught about drainage, ventilation, heating, and so on, and the medical officer of health should visit the schools occasionally to see that the teaching was kept up. With regard to the question of finish, which was mentioned in the paper, the beauty of finish was really a moral quality, and was the expression of a man's pleasure in what he was doing. The value of finish was the endurance it provided. If a cottage was built that was not going to last very long, the various small parts would give way much too soon and disintegrate, and the building would be a ruin long before it should be. In conclusion, he wished to emphasise that the main question was that of education in the villages, and that the young should be taught that they were members of a very large social organism and must play their part in it.

Mr. E. Howard Wilkins thought some of those present were perhaps a little disappointed that the author had not dealt more fully with the practical side of the restoration of ancient cottages. He was very much surprised to hear Mr. Powys say that the Society for the Protection of Ancient Buildings had not yet been able to obtain an example of the restoration of an old cottage in progress and was now seeking to purchase an ancient cottage for that purpose. Personally he had had a considerable amount of practical experience in connection with the matter. In 1913 he acquired two fishermen's cottages in a Sussex village which were in such a dilapidated condition that the local authority contemplated closing them. Much of the work he had had to do on the cottages had been mentioned by the author, for instance, the question of foundations and damp. He found that a very simple method of dealing with that was to dig a trench all round the foundations a foot deep and cement the wall with about 1½ inches of cement concrete a foot below the ground and 9 inches above. That had a very good effect, especially the part which was above the ground, because the cottages were thatched, and a thatched roof where the thatch extended generally about 3 ft. from the wall in its overhang had got no gutter. A gutter was not required, but of course the rain dripped off the roof on to the ground round the wall of the cottage. The way to deal with that was very simple. He purchased from a contractor who had been demolishing the General Post Office a large quantity of broken stones, which he laid together all round the cottage for a distance of about four feet. That took the drip from the thatch, and the cottage, which was formerly damp, was now quite dry. He was sorry the author had not mentioned what his view was on the subject of thatch in restoring ancient cottages. When he examined the roofs of the cottages he had alluded to, he found that many of the rafters were broken and pinned in, it being the custom in re-thatching buildings to put the new thatch on the top of the old. He fixed up a framework inside the roof and strutted it out and put in new rafters in place of the broken ones. When he had restored the cottages his friends were so struck with them that they all wanted to buy old cottages and restore them. One gentleman came down from London and purchased eight old brick cottages, in an L-shaped block, for £225. They were five-roomed cottages, with lofts, and were so dilapidated that they were about to be condemned by the local authority, but they had now been restored and made habitable, and some of them were let furnished to-day for £2 10s. a week. In the restoration of such cottages difficulty was often experienced with the local authority, as, for instance, in the matter of thatching. It was said that thatching was dangerous from the point of view of fire, and it was true that cottages in rows or standing close together should not be thatched, but where they were detached there was no better form of roof for a cottage than thatch, which was warm in winter and cool in summer. The walls of the cottages in Sussex that he had restored were very massive, being composed of solid boulders 18 inches round, the spaces between them being filled in with smaller stones and cement. In order to make the corners square the builders had used any pieces of square stone they could find, and from one of these he had been able to tell the approximate date of the cottage, because it consisted of a tombstone bearing the inscription "Here lieth the body of James Bell," and a date of the seventeenth century.

The Chairman, in proposing a vote of thanks to the author for his interesting paper, said the question dealt with was a very practical one. There were many cottages all over the country which were threatened with demolition, and he did not think it was generally realised how difficult the circumstances were for the owners of the cottages. In the first place there was pressure put upon them on the subject of damp courses, height of rooms, and other matters connected with hygiene, and in the second place there was the fact that the cost of restoration was at least three times as great as it was before the war, and that, owing to all patriotic people having done as little as possible in the way of building during the war, and not being able to get the bricklayers if they wanted to do it, many of the cottages were in a very bad state of repair. The owners had got to make good the four or five years of arrears in the upkeep of the cottages, and they had to do it at three times the former cost. That was a rather serious matter, especially in connection with country cottages, which were often let at a rent of

1s. or 1s. 6d. a week, and made it extremely difficult for the owner, whose income from the cottages probably entirely disappeared and left a considerable deficit. At the present time the owner was not allowed to raise the rent to recoup himself, except under certain special conditions. That was rather unfortunate, because the community wanted the cottages, and it fell to a number of individuals, some of whom simply could not afford it, to repair them for the community at their own expense. It would be very useful if the owners could be helped in any practical way, such as that which the Society for the Protection of Ancient Buildings proposed, *i.e.* to organise advice as to the repair of cottages and to publish pamphlets, etc. Mr. Bernard Shaw, the destroyer, and Mr. Powell, the preserver, were in a way very much akin, because they both looked at the matter from the human end. Mr. Shaw's remarks were simply a paradox by which he wished to emphasise that we had got to do really good work at the present day. The moral of most of the remarks that had been made at the meeting was that a cottage was a good thing and a fine thing when it started at the human end. If a man tried to build something which was artistic, he only produced something artistic, and it had no really permanent value about it at all; but if he started at the human end, and his aim was first and foremost to make a home for a person who deserved one, he would make a really good home. The difficulty at the present day was that the people for whom cottages were being built did not take sufficient interest in the matter to insist on really good homes being built for them. When the ideals of the people were set right and they began to take an interest in the houses they lived in, that state of affairs would be altered.

The resolution of thanks was carried unanimously.

Mr. Powell, in reply, said that in regard to thatching he had always noticed that in England when a roof was being re-thatched the new thatch was put on the top of the old, but in Holland, where he had been during the war, he found that the farmers, who did the work themselves, pulled the thatch right off down to the rafters and started again. As to the inflammable nature of thatch, he remembered a blacksmith's shop on the common at a village near Cambridge, which he was told had never been re-thatched for seventy years, and as he stood near it he saw the sparks were falling in thousands all over it. The secret of that was that the reeds composing it were placed so that there was about one-eighth inch or quarter inch space left at the end, instead of the straws projecting about six inches on the outside, as was generally the case.

The meeting then terminated.

INDIAN INDUSTRIAL DEVELOPMENT.

After considering the views of the Government of India on the report of the above Commission, the Secretary of State, Mr. Montagu, recently wrote a despatch, which has been published in India. He accepts two fundamental principles underlying the recommendations of the Commission. First, that in future Government should play an active part in the industrial development of the country; secondly, that Government cannot undertake the work unless provided with adequate administrative equipment, and unless forearmed with reliable scientific and technical advice. He agrees that suitably equipped organisations should be set up in the Provincial Governments and in the Central Government. In giving effect to this policy, he continues, State assistance will take various forms, such as research, the survey of natural resources, technical and scientific advice, educational facilities, commercial and industrial intelligence, the establishment of pioneering and demonstration factories, financial help, the purchase of Government stores in India, and probably also fiscal measures. He points out that if development is to proceed on sound lines labour must be made more efficient. He notes that the Government of India are not yet prepared to formulate proposals regarding the organisation of the Imperial Department of Industries, but contemplate setting up as an interim authority a Board of Industries and Munitions which would close the war commitments of the Indian Munitions Board taken over from the Commerce and Industries Departments.

In a "resolution" simultaneously issued the Government of India state that they are arranging to constitute committees to deal with the creation of a Chemical Service and of an Indian Stores Department. They have also ordered the reconstitution of the Indian Munitions Board as a Board of Industries and Munitions.

COTTON-GROWING IN ANDALUSIA.

The fact that Spain has begun to realise its economic dependence on foreign countries, and feels that the United States will probably need all its raw cotton for home consumption in textiles, has resulted in the appointment of a Commission which was sent to Andalusia by the Catalan Cotton Committee to investigate the experiments in cotton-growing that have been made in Jerez, Malaga, Murcia, Valencia, and the province of Seville, and to determine the possibility of raising the plant successfully on Spanish soil.

The report of this Commission, writes the United States Consul at Seville, is extremely encouraging. Experiments show that the soil of Andalusia is admirably adapted to cotton-raising, and that, in addition to the land already prepared for other crops such as cereals and vegetables, vast swamps could be reclaimed and utilised for this purpose. It is claimed that one hectare (2·47 acres)

of land will produce 500 kilogs (1,102 lb.) of cotton, and that enough cotton to supply the Spanish market could be raised on 200,000 hectares. This product, the experiments indicate, would be equal in quality to that grown in the United States, although measures would have to be taken to protect the crop from the heavy rains in the autumn.

The farmers are being instructed in the raising of the plant, and the Catalan mill-owners, in whose mills most of the imported cotton is worked into textiles, will assure them a ready market. Agriculturists in the Seville district are showing great interest in the project, and are co-operating enthusiastically with the Catalan Committee.

With regard to the reclaiming of swamp land for the raising of cotton, a movement is on foot under Government control and support to drain the land on the left bank of the Guadalquiver River near its mouth, thereby reclaiming some 37,000 hectares (91,429 acres). This extensive tract comprises the districts lying between Los Palacios, Villafranca, Las Cabezas de San Juan, Lebrija, Trebujena, Sanlucar de Barrameda, and Jerez de la Fronterà. Preliminary surveys have been made, and it is estimated that eight years will be needed to complete the work and an additional two years to free the soil from salt. On account of the annual overflow of the Guadalquiver River, extensive measures will be necessary to provide against floods. An exhaustive study of this problem, extending over a period of two years, has been made by Government engineers, and it is felt that the need of land for cotton-growing will give an added impetus to the Government's plans for reclaiming the district.

COCOA PRODUCTION.

The following notes on the preparation of cocoa beans have been issued by Mr. W. H. Johnson, Director of Agriculture, Ibadan, Southern Provinces, Nigeria :—

Now that the time for the cocoa harvest is approaching, it behoves all those persons who are interested in the rapidly increasing trade in this important staple to encourage the growers to market the crop in the best possible condition. Although the practice of fermenting the beans is much more generally adopted than hitherto, a great deal of the crop is still marketed in an unfermented, or very slightly fermented, condition. The variety of cocoa grown in Nigeria is the same as that grown in Cameroons, yet Cameroons cocoa almost invariably realises about 10*s*. more per cwt. than Nigerian cocoa, simply because it is more carefully cultivated and cured.

Experiments, spread over a period of four years (1912-1916), which were conducted by the Agricultural Department at Agege, amply demonstrated that both the yield and quality of Nigerian cocoa can be greatly improved by adopting better cultural methods and by more careful preparation of the beans. Samples of the cocoa cured during the course of these experiments were reported by the Imperial Institute to be worth 77*s*. to 79*s*. per cwt. at a time that Cameroons cocoa was selling at 74*s*. to 76*s*. 6*d*. per cwt.

Cocoa manufacturers prefer large, plump beans, not only because they have a lower percentage of shell than small beans, but because this appearance indicates that the cocoa has been well grown and harvested when it was properly ripe. Neglected and unhealthy cocoa trees produce undersized pods with small, flat, badly-filled beans. Cocoa beans which are harvested before they are properly ripe do not ferment normally; they have a flat, shrivelled appearance after being cured, and the farmer loses weight by harvesting them. On the other hand, over-ripe beans produce an inferior quality of cocoa; moreover, they may have commenced to germinate, and as a result the germ makes a hole in the shell which affords free access to mould and insects. In the preparation of cocoa powder, germinated beans develop an objectionable flavour and odour, so that manufacturers regard them with intense disfavour. Although less prevalent than hitherto, the practice of washing the beans before drying them is still continued in some districts. This operation is not necessary; it may improve the external appearance of the beans, but it reduces their weight and makes the shell thinner and more susceptible to breakage and insect attack.

The fermentation process performs several useful functions; it removes the sweet pulpy tissue in which the beans are enveloped, and it alters their chemical composition. The bitter taste of the fresh beans is lessened, the peculiar chocolate aroma is developed, the tonic and stimulating principles are liberated, the colour is altered from violet to brown, while the kernel is loosened from its shell and more readily crumbles up when subjected to light pressure. A certain amount of weight is lost during fermentation, but fermented cocoa dries more rapidly than unfermented cocoa.

The period of fermentation necessary is not only dependent upon the variety of cocoa under treatment, but upon climatic conditions as well. Varieties such as Criollo, which produce light-coloured and mild-flavoured beans, require far less fermentation than the bitter-flavoured, violet-coloured beans of the Amelonado variety, which is grown in this country. Fermentation changes take place more rapidly when the weather is hot and moist than when it is dry and cool.

It has been found that Nigerian cocoa generally requires to be fermented for about six days. If, after fermentation, traces of the violet colour are found within the kernel, this is an indication that the period of fermentation has not been sufficiently prolonged. Convenient receptacles in which to ferment the beans are boxes made of Iroko or other durable wood fitted with a movable bottom perforated with holes. The seeds from about 5,000 pods should be placed in one box, and they should be lightly covered with banana leaves; the following

day they should be turned into a second box and thoroughly mixed together during this operation. It will then be observed that the temperature of the beans has risen, but that it is higher in the beans which are best aerated, *i.e.* those situated near the top and the bottom of the box. In order to ensure a uniform fermentation throughout the mass, it is necessary to mix the beans thoroughly and turn them into another box each day. As fermentation proceeds, the pulpy tissue liquefies; to allow this to escape readily the perforations in the bottom of the box are made. If this liquid is allowed to stagnate at the bottom of the box it discolours the beans and injures their flavour. On the morning of the seventh day the beans should be ready for drying. Over-fermentation must be guarded against; the appearance of brownish spots on the seeds is an indication that the time has arrived for them to be dried. They should be spread out thinly on a clean, dry surface, preferably raised above the ground. Drying is facilitated by turning them occasionally so as to expose all sides of the beans to the sun. The "kernels" of properly cured beans may be readily broken up into flakes when lightly pressed between the finger and thumb; they have a sweet chocolate flavour and a brown colour. The external appearance of the beans is improved by rubbing them with the hands before they are dry; this operation imparts a gloss to the shell. During very hot weather it is advisable to pile the moist beans into heaps for two or three hours during the hottest part of the day; if this practice is not followed, the shell is liable to shrivel and assume a brittle consistency, which is readily fractured. All small, shrivelled, and broken beans should be picked out and sold as inferior quality cocoa.

It is important to keep not only the cocoa, but also the vicinity in which it is prepared and stored, in a sanitary condition, for the exposure of cocoa to bad odours is often responsible for that objectionable flavour which it develops in the factory on being roasted, and is described in the trade as "hammy."

THE CORK INDUSTRY IN SARDINIA.

Cork trees are indigenous to Sardinia, and extensive natural forests are to be found upon the mountain slopes in the northern part of the island. The crop is cut every nine years—that is to say, a tree stripped of its bark last season will be left untouched until 1928.

According to a report by the United States Commercial Attaché at Rome, the cork industry is in a flourishing condition, large profits having been made during the war. A large factory at Tempio has recently increased its output to four times its former capacity.

The process of industrial production, as employed in the Tempio factory, is comparatively simple. The dried out bark in its cylindrical form is first thoroughly steamed and flattened out under pressure. It remains in piles for about thirty days and reappears covered with blue mould. The bark is then carefully scraped on both sides and cut into strips corresponding in width to the varying lengths of the cork stoppers desired. These strips are cut by hand into cubes. This process calls for highly skilled labour and an apprenticeship of at least four years.

The cork strips are full of defects, and it requires a skilled hand and eye to secure from the cork the maximum of merchantable material. The cork cubes are put through high-speed finishing machines, which round off the edges and give the required taper. This cutting process involves a waste of 20 per cent., and is being superseded by an abrasive process which wastes less than 3 per cent. The fine cork dust, which is a by-product of the abrasive process, found a ready market in Germany before the war at from 40 to 45 marks per quintal (approximately £20 per ton). The precise use the Germans found for this cork dust is not known to the Sardinian producers.

At Terranova cork is prepared in other forms for export. The best cork is baled in sheets for shipment. The inferior cork is ground to a coarse dust and employed with a magnesium surface finish for sound-proof walls and floor coverings. The war stimulated the cork business principally through the demand for trench mattresses. These cork mattresses, in addition to their light weight, furnish very good protection against cold and moisture.

NOTES ON BOOKS.

Bacteriology and Mycology of Foods.—By Fred Wilbur Tanner, M.S., Ph.D. New York: John Wiley & Sons, Inc.; London: Chapman & Hall, Ltd. 28*s*. net.

In view of the growing recognition of the importance of the subjects with which it deals, this volume should be assured of a welcome from students of the bacteriology and mycology of foods. It is the outcome of a course of lectures at the University of Illinois, designed to meet the needs of those who wished to fit themselves for food control, food chemists, and for those students in household science who possess a sufficient fundamental knowledge of chemistry—a knowledge which, as the author remarks in the preface, is essential for intelligent work in microbiology.

Dr. Tanner begins by describing bacteriological apparatus, media and their preparation, and staining technique. This is followed by chapters dealing with the classification and description of bacteria, methods of sterilisation and disinfection, proteins and carbohydrates, yeasts and moulds, intestinal bacteria, methods of examining and testing air, water hygiene, and milk and milk products. A particularly interesting chapter, illustrated by a number of excellent coloured plates, is devoted to the bacteriology of eggs. Recent experiences at the breakfast table have led the writer of this note to wish that egg dealers

in this country had a better knowledge of the bacteriology of their wares, and he cordially hopes that they will study Dr. Tanner's description of candling and other devices by which they may be saved from labelling as "new laid" eggs which seem to be upon the point of spontaneous combustion.

The remaining chapters treat of meat and meat products, methods of food preservation, and epidemiology.

The treatment of each section is as full and comprehensive as is compatible with keeping the book within reasonable limits; but for those who desire to study any branch in further detail excellent bibliographies are provided, and these add materially to the usefulness of the volume.

English Eighteenth Century Sculptures in Sir John Soane's Museum. By Arthur T. Bolton, F.S.A., F.R.I.B.A. Soane Museum Publications. 2*s*.

One of the principal aims of Sir John Soane in forming the remarkable museum in Lincoln's Inn Fields was to preserve the actual work of artists of his own time, and his collection contains some fine specimens of painting and sculpture of the last half of the eighteenth century and of the first quarter of the nineteenth. The present pamphlet deals with the sculpture of this period, particularly with the work of Chantrey, Banks, Westmacott, Flaxman, and Wedgwood.

The Soane Museum is of special interest because it is housed in the home of its founder, which is still arranged, so far as possible, as he left it. It is, therefore, singularly free from the "museumy" atmosphere that afflicts one in many public collections, and one has the feeling—especially if one is fortunate enough to be taken over the house by Mr. Bolton—that one is being shown over the collection of a connoisseur by the connoisseur himself. Every corner is full of interest, and one can only be amazed at the amount and the variety of the objects that, without undue crowding, are contained in the house. The Museum is certainly a place that ought to be familiar to every one interested in English architecture, sculpture and painting. There is a fairly common impression that very few people go to it. As a matter of fact, many would be surprised to learn the numbers of its visitors which, we understand, are sometimes such as to throw a severe strain on the accommodation provided.

The "Times" Atlas of the World. Part I. Office of the *Times*, Printing House Square. 2*s*. 6*d*.

Part I. of this welcome atlas contains four maps, Scotland (Southern Section), Farther India, Lower Egypt, and Mexico and Central America. It has been prepared under the direction of Dr. T. G. Bartholomew, who has adopted the orographical colouring familiar to all students of maps, with the result that one gets at a glance an impression of the general surface of the country portrayed. The maps are extremely full—the general index will contain over 200,000 names—but they are equally clear, and they will be valuable alike to the serious student of geography and to the man who is planning a holiday tour.

The *Times* is certainly to be congratulated on its enterprise in bringing out this work. The appearance of the various parts will be eagerly awaited, especially of those showing the territorial redistributions ordained by the Peace Conference.

GENERAL NOTES.

Concrete Sheep Barn.—Although the first cost was double that of the usual type of timber building the use of concrete construction in the case of a large double-deck sheep barn at Denver, U.S.A., had the advantage of securing sanitary conditions, protection from fire, and of reducing maintenance charges to a minimum. The structure in question has two decks (one on ground level, and the other superimposed), and is 422 ft. by 320 ft., the stories being 12½ ft. high. There are no side walls, but a 4-ft. high parapet extends around the upper deck. The building is divided by concrete uprights into a number of panels. These panels are 16 ft. by 16 ft. in plan, except for a 20 ft. width at the central portion to provide for a driveway. Internally, arrangements are made in each of the panels for the attachment of fences and gates to form pens. Even the drinking troughs are of concrete. The flat-slab construction for the upper deck is designed for a load of 150 lb. per square foot. A sawtooth roof covers the central portion of the barn; the outer wings at each end (each comprising four panels) have a flat-slab roof, it having been assumed that sufficient light to illuminate the interior would be admitted through the open sides. Concrete ramps, 15 ft. wide, with grades of 16 per cent. for the sheep runs, and 11 per cent. for the driveways handling supplies, reach to the upper deck. A granolithic finish is given to the floors and ramps in order to resist wear from hoofs.

British School of Archæology at Jerusalem.—The emancipation by Great Britain of the Near East involves exceptional responsibilities in relation to the ancient monuments and antiquities. Palestine and Mesopotamia are not only historical areas of supreme interest about which relatively little is known, but they are filled with sacred associations and abound in sites and monuments, familiar by name to almost everyone from childhood, and revered by the great bulk of civilised humanity irrespective of nationality or religious persuasion. The future administrators are faced, then, with the duty of preserving these historical places and the antiquities that will constantly be coming to light. Moreover, competent bodies will now have full opportunity of exploring systematically these ancient sites, so intimately associated

with the origins of the Jewish and Christian religions. It is evident that whether for preservation or for discovery adequate precaution and preparation are indispensable. Public feeling throughout the world will no longer tolerate any neglect in this respect now that these countries are emancipated, but will rightly demand of the governments and the nations that accept the mandates an adequate provision for the protection of these remains of the past, and for better and fuller information concerning them. Yet, at the present time, Great Britain does not possess the number of trained archæologists of the younger generation necessary for this task; and no institution exists within these areas, such as have long been established at Athens and at Rome, suitably organised to provide such training. With a view to remedying this defect and to providing an adequate organisation on the spot to respond to our obligations and opportunities of the future, the British Academy, at the invitation of, and in conjunction with, the Palestine Exploration Fund, and with the concurrence of the Foreign Office, have appointed a Committee (of which the Chairman is Sir F. Kenyon, F.B.A., and the Director Professor J. Garstang) for the purpose of establishing a permanent British School of Archæology at Jerusalem. While the Palestine Exploration Fund will continue its work as before, the objects of the school will be: (1) To facilitate the researches of scholars; (2) to provide instruction and guidance for students; (3) to train Archæological Excavators and Administrators; (4) the school will assist in every possible way the excavations and explorations of the Palestine Exploration Fund. It may from time to time undertake investigations on its own account, and such operations would be conducted in harmony with the work of the Palestine Exploration Fund. The temporary address for all communications is The Secretary, British School, c/o Palestine Exploration Fund, 2, Hinde Street, Manchester Square, London, W. 1.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday afternoons, at 4.30 p.m.:—

February 4.—Alfred E. Hayes, General Secretary, English Language Union, "The English Language and International Trade." Sir Edward W. Brabrook, C.B., will preside.

February 11.—Lieut.-Commander Norman Wilkinson, R.N.V.R., O.B.E., R.O.I., R.I., "Naval Camouflage."

February 18.—Sidney Preston, C.I.E., "English Canals and Inland Waterways." Neville Chamberlain, M.P., will preside.

February 25.—James Currie, C.M.G., Ministry of Labour (Training Department), late Principal, Gordon Memorial College, Khartoum, "Industrial Training."

March 3.—William James Garnett, First Secretary, H.B.M. Diplomatic Service, "Mongolia from the Commercial Point of View."

March 10.—H. M. Thornton, "Gas in relation to Industry and Housing."

March 17.—William Worby Beaumont, M.Inst.C.E., "Street Passenger Transport of London."

March 24.—Air-Commodore Edward Maitland, C.M.G., D.S.O., "The Commercial Future of Airships."

April 14.—Joseph Thorp, "The Fundamental Basis of Good Printing."

Colonial Section.

Tuesday afternoons, at 4.30 p.m.:—

February 3.—Sir Francis Watts, K.C.M.G., D.Sc., Imperial Commissioner of Agriculture for the West Indies, "Tropical Departments of Agriculture, with special reference to the West Indies." Lieut.-Colonel Sir David Prain, C.M.G., C.I.E., LL.D., F.R.S., Director of the Royal Botanic Gardens, Kew, will preside.

March 2.—G. F. Scott Elliot, M.A., B.Sc., F.R.G.S., "Trade Routes for the Empire in Africa." Colonel Sir Thomas H. Holdich, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., will preside.

May 4.—Professor William A. Bone, D.Sc., Ph.D., F.R.S., "Lignite."

Dates to be hereafter announced:—

Charles H. Sherrill, "Stained Glass."

Lady Inglefield, President, Buckinghamshire Lace Association (North Bucks and Bedfordshire), "The Hand-made Lace Industry."

Graily Hewitt, "Rolls of Honour."

Charles Crowther, "The Arts and Crafts of Japan" (with examples from the author's private collection).

William Cramp, D.Sc., M.I.E.E., "Pneumatic Convoying Plants, with special reference to the Transport of Grain."

L. Gaster, "Industrial Lighting in its relation to Efficiency."

Sir Valentine Chirol, "The Enduring Power of Hinduism." (Sir George Birdwood Memorial Lecture.)

Brigadier-General Lord Montagu of Beaulieu, C.S.I., "Roads and Transport in India."

Sir George Cunningham Buchanan, K.C.I.E., M.Inst.C.E., "The Ports of India: their Administration and Development."

CANTOR LECTURES.

Monday evenings, at 8 p.m.:—

CAPTAIN H. HAMSHAW THOMAS, M.B.E., M.A., F.G.S., Fellow of Downing College, Cambridge, and formerly of the Royal Air Force, "Aircraft Photography in War and Peace." Three Lectures.

Syllabus.

LECTURE III. – FEBRUARY 2.—The use of aerial photography in exploration and survey in times of peace—Comparison of a photograph with a map—How maps may be compiled or improved—Application to exploration—Things concealed and revealed—Surveys for special purposes—Limitations and future of the method.

CHARLES FREDERICK CROSS, B.Sc., F.R.S., F.C.S., "Recent Research in Cellulose Industry." Three Lectures.

February 16, 23, March 1.

WALTER ROSENHAIN, B.A., D.Sc., F.R.S., Superintendent, Department of Metallurgy and Metallurgical Chemistry, National Physical Laboratory, "Aluminium and its Alloys." Three Lectures.

April 12, 19, 26.

ARTHUR THOMAS BOLTON, F.R.I.B.A., F.S.A., Curator, Soane Museum, "The Decoration and Architecture of Robert Adam and Sir John Soane, 1758–1837." Three Lectures.

May 3, 10, 17.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, FEBRUARY 2...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Captain H. H. Thomas, "Aircraft Photography in War and Peace." (Lecture III.)

Victoria Institute, Central Hall, Westminster, S.W., 4.30 p.m. Sir Andrew Wingate, "India."

Royal Institution, Albemarle-street, W., 5 p.m. General Monthly Meeting.

British Academy, King's College, Strand, W.C., 5 p.m. Ven. Archdeacon Charles, "The Apocalypse." (Lecture I.)

Chemical Industry, Society of (London Section), at the Chemical Society, Burlington House, W., 8 p.m. Messrs. H. M. Wells and J. E. Southcombe, "The Theory and Practice of Lubrication: The Germ Process."

Geographical Society, Central Hall, Westminster, S.W., 8.30 p.m. Major-General Sir Frederick Sykes, "Air Routes of the Empire."

Actuaries, Institute of, Staple Inn Hall, Holborn, W.C., 5 p.m. 1. Mr. A. Henry, "Some further suggestions on the subject of Approximate Valuations." 2. Mr. H. L. Trachtenberg, "A New Method of Valuing Policies in Groups."

Farmers' Club, at the Surveyors' Institution, 12, Great George-street, S.W., 4 p.m. Mr. Martin H. F. Sutton, "The Future of the Potato Crop, with special reference to Wart Disease and Immune Varieties."

TUESDAY, FEBRUARY 3...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Colonial Section.) Sir Francis Watts, "Tropical Departments of Agriculture, with special reference to the West Indies."

Royal Institution, Albemarle-street, W., 3 p.m. Professor G. Elliot Smith, "The Evolution of Man and the Early History of Civilisation. Lecture II.—Elephants and Ethnologists."

Photographic Society, 35, Russell-square, W.C., 7 p.m. Mr. L. A. Jones, "A Non-Intermittent Sensitometer."

WEDNESDAY, FEBRUARY 4...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Mr. A. E. Hayes, "The English Language and International Trade."

Aëronautical Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Squadron-Leader J. E. M. Pritchard, "Rigid Airships and their Development."

Geological Society, Burlington House, W., 8 p.m.

Automobile Engineers, Institution of, at the Institution of Mechanical Engineers, Storey's-gate, S.W., 8 p.m. Messrs. A. P. Young and H. Warren, "The Process of Ignition."

Public Analysts, Society of, at the Chemical Society, Burlington House, W., 8 p.m. 1. Annual General Meeting. 2. Messrs. F. S. Sinnatt and L. Slater, "An Investigation into the Composition of the Unsaturated Hydrocarbons present in Coal Gas." 3. Mr. H. Trickett, "The Estimation of the Available Oxygen in Sodium Perborate and in Perborate Soap Powders."

Industrial League and Council, Central Hall, Westminster, 7.30 p.m. Major E. A. Pells, "Conditions the Workers may Control."

Royal Archaeological Institute, at the Society of Antiquaries, Burlington House, W., 4.30 p.m. Mr. F. E. Howard, "Some Mid-Suffolk Churches and their Woodwork."

THURSDAY, FEBRUARY 5...Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Linnean Society, Burlington House, W., 5 p.m. Dr. R. R. Gates, "On the Existence of Two Fundamentally Different Types of Characters in Organisms."

Chemical Society, Burlington House, W., 8 p.m.

Royal Institution, Albemarle-street, W., 3 p.m. Mr. A. E. Conrady, "Recent Progress in Applied Optics." (Lecture I.)

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Engineer-Commander E. J. Mowlam, "Naval Pictures."

Dyers and Colourists, Society of (West Riding Section), Leeds. Dr. J. B. Oesch, "Development of the Chemical Industry in Switzerland during the War."

Concrete Institute, 296, Vauxhall Bridge-road, S.W., 6 p.m. Mr. H. K. G. Bamber, "Demonstration on the Practical Testing of Cement."

FRIDAY, FEBRUARY 6...Technical Inspectors' Association, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 7.30 p.m. Mr. J. Waite, "The Treatment of Steel."

Royal Institution, Albemarle-street, W., 9 p.m. Professor Sir Walter Raleigh, "Landor and the Classic Manner."

University of London, University College, Gower-street, W.C., 5 p.m. Dr. T. Borenius, "Mediæval Art." (Lecture IV.)

SATURDAY, FEBRUARY 7...Royal Institution, Albemarle-street, W., 3 p.m. Sir Frank W. Dyson, "The Astronomical Evidence Bearing on Einstein's Theory of Gravitation." (Lecture II.)

Journal of the Royal Society of Arts.

No. 3,507. VOL. LXVIII.

FRIDAY, FEBRUARY 6, 1920.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

WEDNESDAY, FEBRUARY 11th, at 4.30 p.m. (Ordinary Meeting.) LIEUT.-COMMANDER NORMAN WILKINSON, R.N.V.R., O.B.E., R.O.I., R.I., "Naval Camouflage." REAR-ADMIRAL SIR DOUGLAS EGREMONT R. BROWNRIGG, Bt., C.B., will preside.

Further particulars of the Society's meetings will be found at the end of this number.

CONFERENCE ON HOUSE FURNISHINGS.

The Council have arranged to hold a Conference of Manufacturers and Distributors of House Furnishings and of others specially interested in the subject, in connection with the Ideal Home Exhibition at Olympia on Thursday, February 19th, at 3 p.m.

The chair will be taken by the Right Hon. Sir Auckland Geddes, K.C.B., M.P., President of the Board of Trade; Sir Henry Trueman Wood, Chairman of the Council of the Royal Society of Arts, and Sir Frank Baines, C.B.E., M.V.O., Principal Architect of H.M. Office of Works, will also speak, and thereafter the meeting will be invited to take part in a general discussion.

The main object of the conference is to initiate a scheme whereby the manufacturers and distributors in the different industries concerned may have an opportunity for interchanging views with regard to the development of their trades as to both quality and quantity of production. The Society has already convened conferences of manufacturers and distributors in other industries, as an outcome of which standing committees have been formed which will meet from time to time to discuss questions affecting the interests of the trades concerned. It is believed that these will serve a very useful purpose, and in a similar way it is hoped, after the general conference at Olympia, to hold special conferences of manufacturers and distributors of the various articles used in house furnishing.

Fellows of the Society desiring to attend the conference are requested to communicate with the Secretary, who will be glad to forward to them cards of admission to the Exhibition.

CANTOR LECTURE.

On Monday evening, February 2nd, CAPTAIN H. HAMSHAW THOMAS, M.B.E., M.A., F.G.S., Fellow of Downing College, Cambridge, delivered the third and final lecture of his course on "Aircraft Photography in War and Peace."

On the motion of the Chairman, LIEUT.-COLONEL ALLAN J. CUNNINGHAM, a cordial vote of thanks was accorded to Captain Hamshaw Thomas for his interesting course.

The lectures will be published in the *Journal* during the summer recess.

COLONIAL SECTION.

Tuesday afternoon, February 3rd, 1920; LIEUT.-COLONEL SIR DAVID PRAIN, C.M.G., C.I.E., LL.D., F.R.S., Director of the Royal Botanic Gardens, Kew, in the chair. A paper by SIR FRANCIS WATTS, K.C.M.G., D.Sc., Imperial Commissioner of Agriculture for the West Indies, on "Tropical Departments of Agriculture, with special reference to the West Indies," was read by CAPTAIN ARTHUR W. HILL, Sc.D., M.A., F.L.S.

The paper and discussion will be published in a subsequent number of the *Journal*.

EIGHTH ORDINARY MEETING.

WEDNESDAY, FEBRUARY 4th, 1920; SIR EDWARD BRABROOK, C.B., F.S.A., in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Brougham, William Henry Charles, Wallington, Surrey.
Darby-Legge, Captain A. W., R.A.S.C., London.
Doyle, Trevor Mervyn, Sydney, New South Wales.

Early, James Vanner, Witney, Oxon.
Garforth, Sir William E., LL.D., M.Inst.C.E., Pontefract.
Gibson, Alfred Herbert, F.S.S., Harrogate.
Guthrie, Thomas Maule, J.P., Brechin.
Holmes, William, London.
Hoxie, William D., New York City, U.S.A.
Hughman, Ernest Montague, Calcutta, India.
Lovekin, Luther D., Philadelphia, Pa., U.S.A.
Macara, Sir Charles Wright, Bt., Manchester.
Nasmith, Frank, Manchester.
Nicoll, Allardyce, M.A., Horton-cum-Studley, Oxon.
Powell, A. Cecil, Weston-super-Mare.
Shafik Pasha, H. E. Mohamed, Minister of Agriculture, Cairo, Egypt.
Stanners, Robert Whitfield, B.Sc., M.A., Cambridge.
Unwin, Mrs. Jane Cobden, London.
West, Edgar Louis, B.A., Rocester, Staffordshire.
Willson, P. G., London.
Wright, Commander Nathaniel H., U.S. Navy, Washington, D.C., U.S.A.

The following candidates were balloted for and duly elected Fellows of the Society :—

Adams, Sidney James, London.
Arthur, Major Edmond John, Birmingham.
Ashworth, Arthur, Bury.
Calvert, Alderman Joseph, J.P., Middlesbrough.
Clifford, William John, Brockenhurst, Hants.
Colwyn, Right Hon. Lord, Colwyn Bay.
Croft, Cyril Murton, London.
De Cruez, Jos. Alex., London.
Dickinson, Mrs. M., Brighton.
Evans, Joseph S., Commander, U.S. Navy, Washington, D.C., U.S.A.
Froud, Edgar Arnold, London.
Ghatalah, M. H. P., Banganapalle, India.
Goslin, James, Johannesburg, S. Africa.
Greenshields, J. N., K.C., Montreal, Canada.
Griggs, Arthur Robert, Bromley, Kent.
Hart, George Eaton, London.
Hendry, Brigadier-General Patrick W., C.B., Glasgow.
Kelsey, William K., B.A., London.
Knowlton, Elliot Ainsworth, Rochester, U.S.A.
Lawrence, John Edward, London.
Longden, Major Alfred Appleby, D.S.O., London.
Mermoz, Francisco Alberto, Buenos Aires.
Mitchell, John, London.
Mitchell, John M., M.I.Mar.E., Sydney, N.S.W., Australia.
Morrell, Clayton Conyers, London.
Morris, Arthur Percy, B.Sc., Assoc.M.Inst.C.E., Burma.
New Jersey, The Right Rev. Bishop of, Princeton, New Jersey, U.S.A.
Palmer, Austin Norman, New York City, U.S.A.
Penicud, John William, Paris.
Pettigrew, J. Stewart, Glasgow.
Redgate, C., Heanor, Derbyshire.
Rhodes, John Edwin, M.D., Chicago, Illinois, U.S.A.
Sayner, George Smith, Richmond, Surrey.
Shay, Peter Yevent, B.Sc., Sheffield.
Silverman, Professor Alexander, Pittsburgh, Pa., U.S.A.
Spear, William, Edgware, Middlesex.
Stanfield, George John, Carlisle.
Sutherland, Charles H., Nova Scotia, Canada.
Taft, William Howard, LL.D., D.C.L. (Ex-President of the United States), New Haven, Conn., U.S.A.
Tattersall, John, Enschede, Holland.
Thomson, George Clark, Saskatchewan, Canada.
Vaus, Frank H., London.
Walsh, Lawrence J., Southbridge, Mass., U.S.A.
Willis, James Harold, B.Sc., Cardiff.
Woodhouse, William H., Crewe.
Wright, Lieut.-Colonel Clifton Vincent Reynolds, London.

A paper on "The English Language and International Trade" was read by Mr. Alfred E. Hayes, General Secretary English Language Union.

The paper and discussion will be published in a subsequent number of the *Journal*.

PROCEEDINGS OF THE SOCIETY.

SEVENTH ORDINARY MEETING.

Wednesday, January 28th, 1920; Monsieur Emile Cammaerts in the chair.

The Chairman, in introducing Sir Cecil Hertslet, the author of the paper, said he thought his first duty, as one of the representatives of the Anglo-Belgian Union, was to thank the Royal Society of Arts for having afforded their hospitality to the Union and for having organised the present meeting. He wished to take the opportunity to say a few words, not about the general work of the Anglo-Belgian Union, which was carried on with so much activity and devotion by its honorary secretary, Mr. Maudslay, but about a small part of that work, *i.e.* the work of the Educational Committee, which was organising lectures all over the country in order to promote interest in this country in Belgian affairs. He felt sure those present would agree with him that it would be a good thing that the interest in Belgium, which was shown so generously by this country during the war, should not completely die away, but that at least some part of the great flame of enthusiasm that was then kindled should be kept alive. It was for that purpose that the lectures were organised, and, considering the difficulties that had to be overcome, they had met up to the present with considerable success. In the previous winter seventy-five lectures had been delivered, and it was hoped that one hundred would be organised during the present winter. They covered a very wide range and dealt with every possible subject connected with Belgium, such as Belgian history, Belgian art, the position of Belgium during

the war, and social questions, and the audiences to which they were delivered varied from secondary schools to universities, and from workmen's clubs to scientific and literary societies. He was glad to say that the work of the Union was not one-sided. There was not only the work carried out by the British section of the Union in this country; there was also the work carried out in Belgium by the Belgian section. It was not only important that the interest taken by this country in Belgian affairs should not die away, but it was also very important that the interest in British affairs and the appreciation of the work England had done for Belgium should not die away in Belgium itself; that was why the work was really two-sided. In Belgium the work had been delayed, as could well be imagined, by the difficulties of reconstruction, but it had now been very well begun. Several lectures had already been given in Belgium by Belgians conversant with British affairs, and Captain Spicer Simpson, of the British Navy, had just been invited to go for a tour in Belgium to deliver lectures on the efforts of the British Navy during the war, a subject the importance of which was not yet perhaps quite realised in Belgium by every section of the population. Owing to the very limited means available, such work could not be carried out without the support of certain enthusiasts, and among those enthusiasts there was no one who had shown so much vigour, efficiency and activity as Sir Cecil Hertslet, who had already delivered sixty lectures for the Union, entailing extensive tours in France, in the occupied parts of Germany, to which he had been invited by G.H.Q., and in military camps in Ireland. The Union was very grateful to Sir Cecil for the work he had done; he had never been called upon without answering very readily to the appeal. It was all the more gratifying to the Belgians that Sir Cecil was not only a very good friend to them but a very old friend. His knowledge of Belgium dated from long before the war; he had lived in Antwerp as British Consul-General for fifteen years, so that he knew something of the Belgians —he knew their good qualities and he knew their faults. The attitude that Belgium took up in 1914 probably did not surprise Sir Cecil in the least, nor was he surprised probably that some of the Belgian refugees in this country were found divested of the shining armour of Sir Galahad! It was a case where the old friendship proved the true friendship, based upon knowledge, and it was a very precious one because it was not apt to be quickly discouraged. He felt very unfit to take the chair at the present meeting, but he did not wish to miss the opportunity of thanking Sir Cecil Hertslet for all he had done for Belgium. The idea of a Belgian introducing a British lecturer to a British audience struck him as rather original, and he thought it was a crowning proof of Anglo-Belgian friendship. He looked forward to the time when he or any other Belgian speaking in Brussels to a Belgian audience would be introduced by a British resident in Belgium.

The paper read was—

THE RUIN AND RESTORATION OF BELGIUM.

By Sir Cecil Hertslet,

Late H.B.M. Consul-General for Belgium.

It is a matter of very great difficulty for Britons, who live in a country almost untouched by the horrors of war, to realise, even imperfectly, the immensity of the tragedy that has overwhelmed little Belgium—a country placed under the solemn guarantee of the Great Powers, and which, relying on the binding force of that guarantee, honourably fulfilled all its obligations towards Europe, and welcomed within its borders, as honoured guests, the citizens of every country. No charge has been levied against Belgium that she ever deviated by a hair's breadth from her neutrality. Politically, Belgium has been faithfully neutral; socially, she has offered hospitality to all.

At the end of July, 1914, Belgium had attained to a prosperity never before known since the country received from the guaranteeing Powers the gift of national independence. In eighty-four years the population had nearly doubled, and Belgium had become the first country in Europe from no less than four separate points of view: (1) Density of its population—397 per square mile; (2) the yield per acre of its crops; (3) the relative development of its railway system compared with its superficial area; (4) the proportional value of its trade activities compared with its population.

In spite of its narrow territorial limits, Belgium had acquired the fifth rank among the most important trading nations of the world. No wonder that such a great result inspired the cupidity of Belgium's powerful neighbour.

The great city and port of Antwerp, the commercial and maritime metropolis of the country, was at the height of its prosperity, as the number of ships entering the port during the previous year was greater than it had ever been before. The vast river-quay space and dock accommodation was insufficient; many ships wishing to ascend the River Scheldt and enter the harbour were unable to do so, and had to remain at Flushing, at the mouth of the river, until other ships came down the river and made room for them at the quays and docks; and the municipal authorities were occupied in feverishly excavating new docks in order that they might be able to cope with the ever-increasing volume of traffic. This was the position in 1914 at Antwerp, one of the first ports in the world.

The industrial and commercial activities of the country were unceasing. At Liége firearms of all descriptions were being manufactured, iron and steel works were in full operation; miners were hard at work both in the district of Liége and in the neighbourhood of Charleroi. Metallurgical works, including blast furnaces, were busy at Charleroi, where the manufacture of plate and of all kinds of glass was also one of the principal industries. Indeed, almost the whole country was a beehive of industry, and factories innumerable were at work in the districts of Brussels, Antwerp, Charleroi, Mons, and Ghent. Ghent was the cotton capital—the Manchester of Belgium. Here there were more than forty mills, having in all nearly a million and a half spindles.

Although the dark cloud of war was ever overshadowing them, the Belgians were unwilling to believe—and, indeed, until the German ultimatum was sent to them, they were unable to grasp the fact—that to two of the guaranteeing Powers—Germany and Austria-Hungary—their solemn word of honour, given in the name of the Most Holy and Indivisible Trinity, was nothing more valuable than a "scrap of paper."

It is not my intention to dwell upon the massacres, pillages, and outrages of all kinds that disgraced the German army in Belgium during the reign of terror of August and September, 1914. Full details of the atrocities committed by the German troops are given, with irrefutable evidence, in the Report of the British Commission of Inquiry presided over by Viscount Bryce. I am speaking to-day on the ruin of Belgium and the restoration to come, but no picture of the ruin of Belgium would be complete without a brief reference to the appalling events which occurred in the early days of the war, when German Kultur held unrestrained domination over the unfortunate people whose independence and neutrality the King of Prussia had given his solemn word to protect.

The city of Antwerp fell on October 9th, 1914, and with its fall the reign of terror in Belgium came to an end, so far as burnings of churches, destruction of villages, and outrages and massacres were concerned. Telegraphic and postal communication with Antwerp was cut off on the day that I left the city, October 7th, 1914. A few days later the Germans occupied Ostend and the Belgian coast, with the exception of a little strip near Furnes, close to the French frontier. The King and Queen of the Belgians, and the Belgian army, withdrew to a small district behind the lines in the south-western corner of the country, with Ypres as its centre and the Germans—barbarous in their Kultur and merciless in their attitude towards the Belgians—took possession of the whole of the rest of the country, where they exercised so-called civil government.

In October, 1914, Belgium was completely cut off from the outside world, and the country was plunged into dense and impenetrable obscurity for more than four years. News occasionally filtered through by way of Holland, but until the liberation of Belgium no one in England could communicate with Belgium, nor could the Belgians correspond with us.

The method by which the ruin of Belgium was accomplished was not the violence of the savage, pillaging and murdering without control, in a wild orgy of death and destruction, as in the early days of the war, but a cold, calculated scheme of organised theft.

The Germans requisitioned, they sequestrated, or, on the slightest pretext, they simply stole anything and everything they wanted. A German official document, setting forth instructions for the pillage of Belgium, has recently come to light. I will read an extract from it:—

> The great length of the war makes it necessary to collect all available raw materials. The interests of the population of an occupied territory, and even those of neutrals, cannot be put in the balance with those of the German Empire. All hidden stores must be collected, and invaded districts must be exploited to the extreme limit, in the interests of German industry.

A list is then given of the articles which are particularly recommended for seizure: automobiles, oils, seeds, textiles, papers, motors, machines, tools of all sorts, chemical products. And then come directions as to how these are to be obtained.

> Confiscation is the most economical means of procuring what is wanted, as the owners will then receive neither indemnity nor receipt. As much as possible should be confiscated.

This is but another proof that the devastation of Belgium was officially organised. I will repeat the words of a Prussian member of Parliament:—

> All who know the present state of Belgian industry will agree with me that it will take several years before Belgium will be able to think of entering into competition with us Germans in the world market.

Or, again, the German officer superintending the carrying off of the machines from the

Providence Iron Works and Foundries, near Charleroi, remarked :—

It is regrettable, but I am acting under orders from Berlin. Belgium's economic position must be destroyed, and she must be reduced to such a position that she will be unable to produce anything.

Nothing remains of the Providence Works except the walls and the power station. At the foundry the cranes and machinery have been broken up. Even the iron flooring has been removed. The rolling-mills have been dismantled and carried off, the foundations have been blown up with dynamite, the large blast pipes connecting the new and the old works, and the sheds, where stocks of ore and coal were stored, have all disappeared.

This is the state of the Providence Works, one of the most important of its kind in Belgium.

I have been speaking about a single factory, but the same thing occurred in other parts of Belgium. I have a list of the most important factories which have been completely destroyed, and another of those which were partially wrecked. But the Germans did not confine themselves to robbing the country of material only. For example, at the great Cockerill Works, plans, drawings, archives, and the secrets of manufacture were all stolen.

The theft of the machinery from the factories all over Belgium necessarily paralysed all Belgian industries. The machinery had been taken to Germany for the express purpose of enriching that country at the expense of her little neighbour. Selfish persecution for the sake of ruining a rival has never been so disgraceful as this, and it is satisfactory to know that Germany has already been compelled to restore 40,000 tons of material valued at £2,000,000, and that out of 9,797 machines taken away 5,069 have been recovered. The work of the Belgian Commission of recuperation was greatly helped by a complete card index, showing the property stolen and its destination, which, in their hurried retirement in November, 1918, the Germans neglected to take away with them.

The central committee of the heads of the several Belgian industries estimates the loss incurred by those industries at nearly £400,000,000, those most affected being the metal industry and the textiles, which were not only the most important and best equipped but at the same time the ones that were in direct competition with Germany.

Belgium has received from the Allies a right of priority on the indemnity to be recovered from Germany of £100,000,000. It is interesting to compare this figure with Belgium's actual losses on her industries alone.

The Belgian Government has now completed its inquiry on the state of the various industries during the German occupation. With the exception of the coal mines, which were kept going by order of the Germans, and for their benefit since they took 85 per cent. of the production, the ruin of Belgian industry is sufficiently illustrated by the following facts: In 1913, 125 coal mines were active; in 1917, 116. In 1913 coke was made at forty-one works; in 1917, at fourteen. In 1913 the metal industry of Belgium possessed fifty-four blast furnaces; in 1917 only one of those was active. In 1913 there were twenty-nine steel works and twenty-four zinc works. These numbers were reduced in 1917 to four steel works and six zinc works respectively.

What really happened was this. The Germans at first endeavoured to keep the Belgian industries going for their own benefit, and it was only when these attempts failed that they commenced their scheme of systematic destruction.

In the last few months of 1914 and in 1915 the German Governor of Belgium seized every opportunity of reassuring the Belgians, and of endeavouring to convince them of the benevolent intentions of Germany. He pretended that the Empire had one desire only—the restoration of the commercial and industrial life and prosperity of the country, which had been troubled by the events of 1914. He appealed to the goodwill of all Belgians; he urged them to set to work at once at their particular trade or industry in the interest of the country. He faithfully promised them that he would ask of them nothing incompatible with their patriotism. The Belgians were not deceived by this appeal, and when it failed manufacturers were required to work for the German army. If they refused to serve the interests of Germany, their factories were sequestrated, and controlled either by German functionaries, or directly by the army.

In 1917 a decree was issued prohibiting the employment in any factory of more than twelve workmen or the use of a motive power greater than that of five horses. This measure placed at once all the industries in Belgium under German control. Many establishments closed their doors, and thousands of labourers were thrown into the streets.

This led to forced labour and the deportation of Belgians. It is obvious that if the whole

of the able-bodied population was compelled to work for the enemy, or suffered—as an alternative—deportation, the industrial life of the country must cease, and that by this means Germany, if unable to lay hands on the Belgian industries, would be able to exploit Belgian labour.

Two protests against the deportations were made in 1916, one by Cardinal Mercier, the other by Belgian workmen. Cardinal Mercier's protest was made in the name of the Belgian Episcopate, and, like the workmen's appeal, was a lengthy document. I will give a few of its salient features. It was called "The Cry of Alarm of the Belgian Bishops to Public Opinion," and stated that every day the German military authorities deported from Belgium to Germany thousands of inoffensive citizens who had to submit to forced labour. On October 16th, 1916, the Cardinal made a formal protest to the German Governor of Belgium, and sent a copy of his protest to the representatives at Brussels of the Pope, Spain, the United States, and Holland. When the protest was made it was no longer a question of forced labour in Belgium, but in Germany, for the profit of the Germans. The Germans made many excuses for the deportations, but the plain truth, declared the Cardinal, was that every deported workman was one soldier more for the German army. He took the place of a German workman who was at once enlisted.

Cardinal Mercier stated that the Germans enrolled the unemployed, assuredly, but they recruited also, in great numbers, amounting in the Mons district alone to more than a quarter of the whole, men who had never ceased to work and who belonged to the most diversified trades and professions—butchers, bakers, master-tailors, workmen in breweries, electricians, gardeners; they even went so far as to take all the young people, students at the colleges, at the universities, and at the more advanced schools. And yet two high authorities of the German Empire had formally guaranteed to him the liberty of his fellow-countrymen. Cardinal Mercier concluded his impassioned Cry of Alarm in these words: "May Divine Providence inspire whoever may possess an authority, a word, a pen, to rally round the humble Belgian flag for the abolition of European slavery!"

On November 19th, 1916, the workmen of Belgium, whose delegates met in secret, issued an appeal to the workmen of the world, which was issued in the name of them all, without distinction of party or religion. This document gave an account of the martyrdom of Belgium. It stated that the country had been made a prison, that its frontiers had been armed against the Belgians, as if those frontiers were a battle front, by entrenchments, by barbed and electrified wire, and guarded by sentinels, and that all their constitutional liberties had been abolished. It went on to say that Germany had mulcted its victims in an immense war contribution which had already exceeded £40,000,000, and which increased at the rate of £1,600,000 a month; that Germany had taken away, under the form of pillage, confiscation, requisitions, and forced sales, more than £200,000,000 worth of provisions and goods of all descriptions, as well as industrial and agricultural products. At the same time she had removed to Germany the greater part of the material of the factories, the machines and their accessories, and had thus caused a stoppage of all industries and had brought about a want of employment, which was almost universal among the working population.

The Belgian workmen brushed on one side the German argument that the want of employment was attributable to the Allied blockade. On the contrary, they distinctly stated that the Germans themselves created this want of employment in order that they might turn it to their own profit; and they laid stress on the fact that Great Britain had consented to permit the Belgians to import raw materials, but that the Germans refused to allow diplomatic control by a neutral Power, which was an indispensable condition to prevent those raw materials from being taken by Germany. Moreover, Belgian towns, industrial associations, and men of standing in the country, were forbidden under severe penalties, to give work to the unemployed, to allow their professional education to be carried on, or to employ them on works of public utility. By these devices in November, 1916, about 500,000 Belgian workmen had been reduced to idleness, and to these 500,000 involuntary idlers, created by Germany and kept in idleness by that country, the German taskmasters gave the dread alternative of either working for Germany or of being reduced to a state of slavery. The fate of these Belgian workmen was either exile and deportation, or forced labour, to the profit of the enemy and against their own country. No crueller fate had ever been reserved for criminals by tyrants in days gone by. And what, indeed, was the crime committed by these men? Involuntary idleness, which the tyrant himself had created and

maintained. For this, Belgian workmen were arrested by thousands every day; they were torn away from their wives and children; surrounded by bayonets they were dragged to cattle trucks and carried off either to Germany or to the German trenches in France. In Germany they were cast into the mines, stone quarries, or limekilns, whatever might be their age, their trade, or profession. Young people of seventeen years of age were deported, as well as men of sixty years and upwards.

The Belgian workmen concluded in these simple, dignified, and patriotic words: "Whatever tortures we have to suffer, we only wish for peace when our country is independent and justice has triumphed."

And yet, with the whole story of the deportations known to the civilised world, and with countless other indications against it, the German Government, in its reply to President Wilson of October 21st, 1918, had the effrontery to "protest against the reproach of illegal and inhumane actions made against the German land and sea forces and thereby against the German people."

I have spoken in some detail of the deportations, as the Germans brought about the ruin of Belgium quite as much by deporting the labourers as by the fines, requisitions, and the removal of machinery from the factories.

The most crying wrongs of the Belgian people may be summarised as follows (I have taken the figures from the report of the commission of inquiry instituted by the Belgian Government):—

More than 6,400 inoffensive civilians, among whom were priests, men more than 80 years old, nearly 600 women and 500 children, some of whom were only a few months old, were massacred by rifle fire, bayonet thrust, or even by machine guns, on the pretext that they had fired upon the Germans. 150,000 persons were deported to the enemy front or to Germany, of whom more than 5,200 died. 20,000 houses, many churches, and the University of Louvain, with its celebrated library, were destroyed by fire, which no necessity of war could possibly justify.

I have already mentioned that the loss to the Belgian industries is estimated at £400,000,000. In addition, every year Germany set apart £3,200,000 from the Belgian budget to be devoted to purely German purposes. Apart from the special contributions levied on the cities, Germany exacted a war tax of £1,600,000 every month from the whole country, which was raised progressively to £2,000,000 and £2,400,000.

With regard to requisitions, it will be sufficient to mention that the country was gradually emptied of all raw materials, and that even in private houses every article in copper and brass, and all the wool, were seized.

The distribution of all foodstuffs was controlled and centralised by the German administration in the interest of Germany. If the Belgians had had to live on the scanty supply which still remained over after German wants had been supplied, and had not been helped by the inter-allied Commission for relief in Belgium, a famine in the country could not have been avoided.

Belgium was robbed of 34 per cent. of its cattle, including 322,850 cows, but the Treaty of Peace only provided for the restitution to Belgium of 50,000 cows and 40,000 heifers. One would have thought that this small proportion of the stolen property would have been restored to Belgium by Germany without demur, but difficulties have been raised, and it has been suggested that Germany should be allowed to retain all the milch cows which are now in that country, in complete disregard of the fact that even if there is a scarcity of milk in Germany, the Belgians suffered unjustly in this respect all through the German occupation, and that at present there is a shortage of milk in Belgium, especially in Flanders.

Now that we have witnessed the ordeal that Belgium experienced, and the tremendous losses inflicted upon her, we may be able to understand the difficulties experienced since the Armistice and the amount of energy which has been put into the work of reconstruction. When I went back to Antwerp a few days after the Germans had left the town, I found a dead city and an empty harbour. Railways, bridges, and roads had been destroyed by the retreating enemy over more than half of the country. Canals were blocked with masonry and sunken barges. Almost every industry was at a standstill, and wherever the works had not been destroyed or machinery removed, lack of raw material and fuel prevented any activity. Workmen without employment wandered aimlessly about in small groups, and the children especially showed evident signs of underfeeding and misery. Three and a half million persons were still more or less dependent on relief, nearly a million were completely out of work. Even the fields, which I was accustomed to see so well cared for before the war, showed

evident signs of neglect. There were scarcely any draught animals, and a few lean cows grazing in the pastures were only a shadow of the numerous and well-nourished herds to which Flanders owed its reputation as a cattle-grazing country. To cope with such a desperate situation the Government lacked, for a long time, the necessary credits, since it was only in May last that Belgium was assured by the Allies of definite financial compensation, including the remission of her war debts due to them.

In spite of these unavoidable delays, the high cost of living and the almost insuperable difficulties of securing raw materials during the first months, the situation improved rapidly. It is not in the Belgian temperament to hanker after the impossible, or to spend its energy in vain regrets. I have had several opportunities of visiting Belgium since the spring of last year, and each visit marked a new stage of progress. Some discontent was shown in regard to the high cost of living, the low exchange of the franc, and the failure at the time to obtain satisfaction in the revision of the 1839 treaties with regard to the military security of the country, but everyone seemed eager to work and to make full use of the opportunities afforded by the financial settlement. The railway communications were practically restored, and the traffic in passengers and merchandise reached from 60 to 70 per cent. of pre-war standard. Owing to numerous public works undertaken in every part of the country, and to the re-starting of certain industries, the number of unemployed was reduced to 200,000, and the relief work had almost ceased to exist. I could no longer see any sign of the despondent idleness of the days immediately following the Armistice; streets were crowded with people, but their movements were no longer purposeless, the business activity of pre-war days was already restored. Production in the mining districts which were the least affected by the occupation had reached 85 per cent. of the pre-war output, part of this coal being exported. Round Ghent the spinning-mills were practically all working, and the town was again surrounded with its girdle of smoking factories. The number of spindles of cotton produced in November last was 1,200,000 against an average of 1,700,000 in pre-war days. Similar progress has been made all over the country by the sugar factories, which, depending mostly on the beetroot crops, were some of the first to be restarted, the production being already considerable enough to allow export. Though the production of glass-works is only a little over 30 per cent. of pre-war standard (1,500,000 square metres per month against 3,750,000 in pre-war days) glass is already one of the main articles of export. As soon as exports can be increased the value of the franc is bound to improve, and in the policy of increasing production as much as possible, in order that exports may be increased, the Government is greatly helped by employers and workmen alike.

There have been some labour troubles in Belgium lately, as in every other industrial country, but most of them have been arranged amicably. Within the last year 145 disputes have been settled by arbitration, notwithstanding the considerable progress made by the trade unions, as well as by the Socialist party, which is strongly represented in the present Government. This conciliatory spirit may be largely attributed to the patriotism of the masses stirred by common sufferings under German occupation, and to the fact that instead of being wearied by over-production and extra hours during the war, most of the Belgian workmen were only too eager to resume work after long years of forced idleness.

In regard to shipping at Antwerp the position has wonderfully improved since the Armistice. Owing to the closing of the Scheldt during the war, all navigation ceased. The system of railway lines serving the docks and river-quays had become overgrown with grass and weeds. The river was silent and deserted. Now all is changed. 2,404 ships, with a tonnage of 2,603,584 tons, entered the port during the first seven months of 1919. This represents nearly a third of the shipping that entered Antwerp during the first seven months of 1914, and the progress is still going on from month to month.

At the same time, it must be admitted that the adverse trade balance is still serious, the annual excess of imports over exports having risen from £40,000,000 in pre-war days to £112,000,000 in 1919. Many months must elapse before the metal industry in particular, which suffered the most severely of all, will attain to its former prosperity.

The housing problem is a difficulty in Belgium, as it is in this country. The country has lost 150,000 dwellings through the war and the paralysis of the building trade during the German occupation, while in the devastated area only 4,000 houses have up to the present time been erected. This question and the general one of the restoration of the Yser district is now engaging the earnest consideration of the

Belgian Government, and there is every hope that great progress will be made in the course of the present year.

I have alluded to the progress made by Belgium from 1830, the year of her independence, until 1914, when the country was crushed by the war. We are now witnessing a similar revival, but this should not make us forget the tragedy of the German invasion and occupation.

The years fly quickly by, and the early days of the war have already passed into history, but the world, and in particular the British Empire and France, should never forget what Belgium did in those fateful days more than five years ago. The immensity of Belgium's overwhelming sacrifices will, however, be fully realised by the generations to come. We ourselves are living in the midst of events that have shaken the world to its foundations, and it is almost impossible for us to view the great struggle between liberty and tyranny in its proper perspective. That is why it is so difficult for us to appreciate at its true value the greatness of Belgium's decision at the beginning of August, 1914. Still, it is well for us to remember what would most certainly have happened if Belgium had decided to submit to the German ultimatum, and to allow the German army a right of way over Belgian soil. If the King of the Belgians had allowed the German army an unopposed passage across Belgian territory, if neither Liége nor Antwerp had offered resistance to the invader, then Dunkirk, Calais and Boulogne would have fallen into the power of the Germans before it had been possible for us to throw a single division into France. There would have been no resistance of the British Army at Mons, no Battle of the Marne, and the fate of Paris would have been sealed.

Honour and gratitude compel us, therefore, as a nation, to do everything in our power to restore Belgium to her former prosperity. Our own interests, too, demand this, as you cannot fail to realise, if you reflect on what our position would be if, through a lack of sympathy on our part, Belgium should fall in the future under the commercial domination of Germany. I trust, therefore, that on grounds of gratitude, patriotism, and in the interests of the British Empire, the closest understanding may never cease to exist between our own country and restored and liberated Belgium.

DISCUSSION.

THE CHAIRMAN (M. Emile Cammaerts), in moving a vote of thanks to the author for his paper, said everyone present must have felt the eloquence of certain of the figures quoted in the paper. There was sometimes a prejudice in artistic and literary circles against figures, but when one heard of the fifty-four blast furnaces in Belgium in 1913 being reduced to one in 1917, and having already increased to eleven, he thought there were very few poems written about the resistance and struggle of the civilian population in Belgium during German occupation which were more eloquent or inspiring than those three figures.

H.E. THE BELGIAN AMBASSADOR (Baron Moncheur) said he felt sure he was voicing the sentiments of all Belgians present when he expressed to the author the feelings of deep gratitude evoked by his interesting paper. In fair days and in foul, Sir Cecil had shown himself the true and staunch friend of Belgium. For many years he occupied the important post of Consul-General at Antwerp, and during those years he witnessed the prodigious development of that great port. Personally he was convinced that the constant increase of the trade relations between Great Britain and Belgium was very largely due to Sir Cecil's untiring efforts. When Belgium was reduced to that pitiable state of ruin of which so heartrending a description had been given in the paper, the author never ceased to make full use of his great influence in the positions he occupied in London in order to help the Belgian Government in its difficult task of succouring the unhappy Belgians, who had been reduced to so pitiable a condition under the yoke of the tyrant enemy. It was the privilege of the Belgians to show their gratitude in a manner no less flattering than spontaneous by the hearty welcome they gave the author when, following close upon the victorious armies of the Allies, he returned to Antwerp, which had really become his second home. It was not to be wondered at that when the people of Belgium realised that the author was leaving their country for good they should have been really grieved, but, even now that he had retired to a well-earned rest after a long and strenuous career, he never ceased to show his kind solicitude and devotion to Belgium, especially in his capacity of honorary treasurer of the Anglo-Belgian Union. The author had indeed nobly and eloquently depicted the situation of Belgium, which had now risen again and set out full of hope and energy on the road to progress and prosperity, and the grateful hearts of her people would never forget the author's share in the great work of her national resurrection.

LORD ASKWITH, K.C.B., LL.D., said he desired to endorse, on behalf of those present who were of British nationality, the eloquent words which His Excellency had uttered with regard to the paper. The interesting collection of facts and lantern-slides presented showed in connected sequence the events that had taken place in Belgium

during the last five years. The author generally backed up his arguments by facts. He was a man to whom Londoners should be grateful for the way in which he brought before them the fact that it was necessary to darken their lights when the German aeroplanes came over, and it was largely due to his influence that London made, perhaps, the greatest mass effort of the war, when everyone watched his neighbour more carefully than he had ever done in his life before. There were two points in the paper on which he would like to say a few words. The slides that had been shown depicted some of the wonderful examples of destruction wrought by the Germans just before their leaving Belgium. Personally, he thought that was one of the most harsh things the Germans did—that, having made use of the country as far as they could during the war, they should, when they found they could not remain there any longer, have gone in for wanton destruction in order that the Belgian people might not be competitors with them after the war. When he visited Belgium last August, he went, on the advice of his namesake — who was now contesting Paisley, and who told him that the works were the most marvellous instance of scientific destruction he had ever seen—to the great factory founded years ago near Liége by an Englishman. He was taken by the head of the firm to a platform from which he was told he would see what had been one of the most up-to-date engineering shops in the world. He expected much, but not all that he saw—he did not expect to see such a mass of concrete foundations blown up by gelignite, of twisted iron and steel, of girders cut off in such a manner that no new engines or machines could be put upon those foundations or so twisted that they could not be dealt with in any way whatsoever. It was indeed a terrible sight, and the slides that had been shown that afternoon depicted destruction of the same nature that had been carried out in other places. The second point in the paper to which he wished to allude was the passage referring to the progressive movement in Belgium. He had the pleasure of visiting Belgium at the end of August and at the end of December, partly in connection with the work of the *lycée* in London for the education of Belgian children during the war, and partly in connection with the establishment of an Anglo-Belgian Y.M.C.A., which the Belgian people had taken up very actively, largely at the desire of their soldiers, for the benefit of the army. On his second visit he noticed that a very remarkable change of atmosphere had taken place since his visit in August. In August there was still some of the apathy engendered by the war, such apathy as might even now be seen in the devastated regions of France, and there was a feeling that the lack of raw materials would keep a large number of people unemployed for many months, particularly in the textile trade. Although the harvest was then being got in, with an extraordinary absence of reaping machines—which were seen in numbers, possibly taken from Belgium, immediately over the German border—there was not the same energy or movement as was apparent in December. In December it struck him that a great change had taken place. At Charleroi they were even indulging in a strike, which, however, the Prime Minister, M. de la Croix, successfully managed to settle. There was pleasure—mitigated, he feared, now—that the Belgian franc was even at a higher rate of exchange than the French, and there was a movement and a desire to go ahead and to determine that the Germans, in spite of their destruction, should not have the upper hand of the Belgians in trade and in commerce. Relying largely on the good offices and friendship of this country to help them where it was feasible, the Belgians were determined to advance on the road to prosperity and to the restoration of that stability which alone would enable them to make progress in the future.

Lord Emmott, P.C., G.C.M.G., G.B.E., said he had listened with the greatest possible interest to the extremely able and well-balanced description of Belgium which had been given in the paper, and wished to associate himself with the eloquent words of thanks which His Excellency had used in supporting the vote of thanks proposed by the Chairman. He had for long been connected with the Anglo-Belgian Union, and in the previous July he had the great pleasure of visiting Belgium with a number of those associated with the Anglo-Belgian Union, and saw the scientific destruction at the Providence Works, which had been so well described in the paper. He also saw many of the other places mentioned by the author, for the tour included a visit to Dinant, where the horrible massacres occurred. He was delighted to hear that a much more hopeful feeling existed in Belgium to-day than there was in July. He was hopeful then that the feeling would soon improve, and he was very glad to hear progress had been made since that time. On the one or two occasions when he had the honour of addressing Belgian audiences he took the liberty of saying: "We are doing all that we can to help in our little way and to see that you obtain raw material, and if you will only avoid labour troubles I do honestly believe that you may still have before you a very great industrial future, which will compare favourably even with your past industrial eminence." He also said one other thing, which he would repeat now: "I do wish that we could have brought with us in this deputation to Belgium a large number of British workers, who might see what war really means and what a devastated country is like, and who might appreciate how intensely anxious the great mass of the people of Belgium are simply to get to honest work again in order that they may be earning their living and feeling that the country is making some progress." He still wished that, because it was worth noting that, whilst our real obligation to Belgium was a moral obligation, yet entirely beyond that we had also a great immediate interest in seeing Belgium prosperous, as well as in seeing our Allies and the other countries of the world prosperous, in order that we might ourselves

do a mutually advantageous trade with them. A great many of the workers in this country did not understand how much one country was dependent upon another, how we prospered most when other countries prospered too. He thought the people of this country were rather too much inclined to look at their own affairs and to forget that we, with our world-wide trade, were dependent upon the rest of the world as well as upon what we could do for ourselves in our own country. He had the greatest possible pleasure in supporting the resolution of thanks to the author.

MRS. W. ROWLAND FISHER said it might be of some interest to those present to hear what the author had said corroborated by one who went over to Belgium in February last, only three months after the Germans had left the country. She and her husband were given passports before the general public, and went over on a refugee boat to Antwerp, taking with them twenty-three little Belgian girls who had been at a home in this country since the early days of the war. Belgium, at the time of her visit, was exactly as the author had described it. Antwerp was like a dead city—there was no traffic, everyone wore dark clothes, and the place seemed as though it had a blight on it. People who wanted to leave Antwerp by train had to arrive at the station three-quarters of an hour before the train started if they wanted to get into a carriage that had any glass in the windows, although there was snow on the ground at the time and the weather was very cold. After visiting Antwerp she went on to Louvain, Malines, Brussels and Dixmude. Dixmude, which had once been a prosperous city, was simply a heap of stones. The condition of that town, however, was the result of war, whereas the condition of Louvain was the result of wickedness. Every other house in Louvain, and in some cases whole streets, as well as the University, had been deliberately destroyed by the Germans. One of the Belgians said to her: "The difficulty in Belgium of getting straight is that everything is upside down, we have not got anything." In Northern France there might be more devastation, but the rest of the country was untouched; they had got some trains that were not smashed up, and some factories that were not destroyed; but in Belgium there was nothing. Of course that was some time ago now, and matters had been improving since then. One thing that struck her very much at the time was that the Belgians seemed to appeal so much to the English to help them to get straight again. She tried to tell them that England also had difficulties to deal with owing to the war, but of course the Belgians looked to England and the other Allies to help them. She still kept up a constant correspondence with the children and with their parents, who were all most grateful for the happy time the children had spent in England.

The resolution of thanks was carried unanimously, and a vote of thanks to the Chairman terminated the meeting.

THE BATTICK INDUSTRY IN JAVA.*

The Battick process is a dyeing process, with this restriction, however, that part of the cloth is made immune to the dyestuff beforehand, in order to form a design.

This method originates from the times when only vegetable native dyestuffs were available. This class of dyestuffs only gradually gives the right shade to the cloth, thus necessitating a long contact between cloth and dyestuff, which is quite out of the question when a printing method is applied. The battick process, however, allows the cloth to remain in the dye-tub as long as desirable.

Those parts of the cloth that should not come into contact with the dyestuff are simply covered with a wax mixture on both sides of the cloth.

On first class battícks, or on batticks made for private use, the wax figures are drawn on the cloth by means of a small instrument called "Tjanting." This consists of a reservoir which contains the liquid wax-mixture, and a small tube, which enables the operator to bring the wax on the cloth. The handling of the instrument therefore has some resemblance to painting.

The method above described, however, is not suitable for industrial purposes, because it takes too long to complete a battick. Generally, brass or copper stamps are used, which enable the workman to stamp in a very short time all wax figures, which are repeated regularly in the design.

Several nice old designs of historical value are known, but the demand for novelties, and the fact that a great number of Europeans and Chinese have become employers in this line of industry, have caused the production of innumerable new designs, which are, however, often very poor from an artistic point of view.

The principal materials for this industry are white cotton cambrics, imported from Europe in various qualities. In the last few years, however, grey supers are also more and more used instead of cambrics. This is to be put down to the high prices ranging nowadays for cambrics as a result of the prevailing circumstances due to the war. Formerly supers were exclusively imported from Europe, but as the Japanese industry is making more and more headway in this respect, now supers are also imported from Japan.

The white cotton cambrics are imported in various finishes, principally to be divided into soft, medium, and hard finish. Certain districts prefer a particular finish, depending upon the process followed by the workmen.

The principal purpose of the finish is to prevent the wax from coming into too close a contact with the cloth, as otherwise great difficulties are experienced in removing the wax afterwards.

In some districts the cloth is impregnated with a mixture of "djarak" or "katjang" oil, in consequence of which the cloth is said to absorb

* The information in this article has been supplied by Messrs. Geo. Wehry & Co., of Batavia, through H.B.M. Consul-General at Batavia, for the Director of the British Institute of Industrial Art.

the dyestuff more easily. When this process is followed, a pure finished cloth is preferred.

Imports of cambrics.—The following are the totals of bales imported into Sourabaya during 1914-18:—

1914 . . .	5,051 bales.	1,171 cases.
1915 . . .	6,167 ,,	1,773 ,,
1916 . . .	5,601 ,,	2,051 ,,
1917 . . .	4,575 ,,	971 ,,
1918 . . .	2,566 ,,	81 ,,

The figures mentioned above are taken from the Government statistics. These statistics, however, only mention the number of pieces. For this reason we have reduced the number of pieces of standard bales of—

300 15-yards pieces,
150 30-yards pieces, and
100 45-yards pieces.

The above figures only apply to the imports of Sourabaya. It should be borne in mind that in Sourabaya only two-fifths of the total imports of the whole archipelago are handled.

Wax used in the battick industry.—As a rule, no pure wax is used, but a mixture of mineral wax (one of the products of the paraffin oil refineries working in this country), animal fat, and rosin. The rosin is imported from America in large quantities, and so far imports have been sufficient to keep the industry going.

Dyestuffs used in the battick industry.—Two dyestuffs are of predominating importance, viz., *indigo* and *alizarine* red. The following table gives the imports in Sourabaya from 1914 up till May, 1918:—

	Indigo.	Alizarine.
1914 . .	161,670 kilos.	68,050 kilos.
1915 .	21,300 ,,	—
1916 . .	66,000 ,,	34,520 ,,
1917 . .	—	—
Jan.-May, 1918	—	—

This statement shows better than words can tell how abnormally small imports of dyestuffs have been during wartime. One might wonder how it has been possible, nevertheless, to keep the industry going so long. The high prices asked for all battick dyes have been of great importance in this respect, as they have forced the natives to work more economically.

At present, however, stocks of European dyestuffs are almost exhausted, and it is to be feared that within a few months the greater part of the employers will have to close their workshops. As a matter of fact, hundreds of the smaller employers have already stopped working at present.

The economical interests of the native population, as well as the selling possibilities for (principally British) white cotton cambrics make the problem of further supplies of dyestuffs a question of vital importance for everybody interested in this trade.

In some districts the native indigo has replaced to some extent the use of synthetic indigo. Great difficulties are, however, experienced, as dyeing with those vegetable dyestuffs takes much more time than is necessary when European indigo is used; consequently a quick production is impossible, which is an almost unsurmountable difficulty for the natives, working with a very limited capital. The native indigo will therefore prove to be unsuitable, at least on a big scale, as a remedy for the shortage of dyestuffs.

For alizarine the position is still much worse, as there are practically no other dyestuffs available which can replace the European alizarine to any important extent.

When going through the samples of batticks obtained from our Sourabaya office, for instance, it is noticed that not a single district in the Sourabaya territory can do without this dyestuff.

Without any doubt we shall see a heavy falling off in the turnover of white cotton cambrics within the next few months on account of the lack of stocks of alizarine.

There are still some other colours which are badly wanted, as *e.g.* yellow (aurimin and azoflavin), violet, and green. The quantities used of these dyestuffs are much smaller, but still the battick industry can hardly do without them. Especially the yellow dyestuffs (aurimin and azoflavin) are absolutely wanted.

We might mention here that several efforts have been made to obtain dyestuffs from England, United States of America, and Japan, but so far without any marked success.

The principal battick centres in the Sourabaya district are Toeloeng Agoeng (Residency Kediri); Kedong, Tjankring, and Bangil, near Sourabaya; Grissee, also near Sourabaya.

In all these places an extensive trade in batticks is carried on with the other parts of Java and the other islands of the Dutch East Indian Archipelago. Large quantities are also exported to Singapore, and hence distributed all through the Straits Settlements. As regards exports, the island of Madoera is of minor importance. This island only exports limited quantities to the Madurese parts of Java (Residencies of Pasoeroean and Besoeki). Still the Madurese batticks are of some interest, as both the process and designs are rather different from those in Java. Consequently Madurese batticks have a charm of their own, especially as they represent rather superior work.

With regard to West Java we might mention that the industry is of minor importance; only in the neighbourhood of Batavia are a few employers, but their output is comparatively small. They all imitate the designs of Solo and East Java, original designs being hardly manufactured in these parts.

We yet have to mention the imitation batticks, a product of the Dutch industry, which are imported here on a large scale. The European batticks are obtained by a simple printing process on one side only of the cloth. These printed imitations can easily be detected, as the colours are much livelier on the front than on the back. Generally European printers use the Pekalongan designs, as they are much beloved by the Javanese.

In the last few months Japanese imitations have appeared also in the Java market, but as these imitations are of a very inferior quality, so far they have not met with any success. It may be possible that the Japanese industry will produce a better article in times to come, but so far their imitations have been very poor.

COTTON-GLOVE INDUSTRY IN ST. GALL.

One of the most important and significant features of the introduction into Switzerland during the war of industries of which the Germans had a pre-war monoply, or a predominance at least, is that of woven, knitted or imitation suede cotton gloves. To the district in and around Chemnitz, in Germany, is due the credit of the inception of this industry and its gradual development to the extent that just before the war it had become almost a world monopoly. Ninety per cent. of the pre-war imports into Switzerland of these goods came from Germany, almost all from the Chemnitz district, the industry being at that time non-existent in Switzerland.

The materials for the manufacture of these cotton gloves in the Chemnitz district before the war were either imported in the form of yarns from the United Kingdom or were spun in Germany from Egyptian cotton. As the war progressed, the lack of raw materials no doubt reached a stage where the Chemnitz factories were obliged to suspend, almost entirely, operations in this line. Consequently, Switzerland's imports gradually diminished during the war.

In order to meet the local demand for these articles, writes the United States Consul at St. Gall, certain Swiss manufacturers investigated local conditions to see if it might be worth while to introduce the industry into Switzerland. The St. Gall district, which is almost entirely given over to the manufacture of cotton embroideries and kindred articles, was found especially adaptable; and in the spring of 1917 a Swiss firm of handkerchief manufacturers at St. Gall started a small factory at Rorschach on Lake Constance. As the industry was entirely new to Switzerland, it was necessary to secure machines and operators from the Chemnitz district. Accordingly the firm imported about ten knitting looms (known in Germany as Kettenwirkstuhl), which were especially adapted to the manufacture of these gloves. The firm secured also the services of an expert German foreman who had been employed for years in one of the largest of the Chemnitz factories. This man went to Switzerland in the spring of 1917, taking with him about forty German girls whom he had selected from various factories to train the inexperienced Swiss girls.

When the progress of the factory reached a certain stage the firm dispensed with the services of their German foreman, permitting him to be engaged by another St. Gall firm, which in October, 1917, had also organised a branch for the manufacture of knitted cotton gloves. As the first venture became more and more successful and its output gradually increased, the services of the German girl employees were dispensed with, their place being taken by Swiss girls.

The cotton used in the manufacture of these gloves is either Louisiana or Egyptian which is spun in England and runs in numbers from 60 to 90. The silk is purchased from Swiss firms.

The first-mentioned factory has two warping machines, which lay out warps having lengths of some 250 yards. The knotting looms produce a cloth having a width of 68 inches; and since each machine has a daily output of 37 square yards of cloth, and each square yard makes ten pairs of gloves, the daily production of the ten machines must be 370 square yards of cloth, from which are made approximately 300 pairs of gloves. At this rate the annual production is about 90,000 dozen. As the average weight of a dozen is about 300 grammes the factory must use approximately 200 lb. of cotton a day.

The cloths after production are dyed or bleached by local firms at Romanshorn, near Rorschach, the dye commonly used being black or beige. Each of the various machines used in the manufacture has its especial work, such as cutting according to size or shape of gloves, sewing on braid and buttons, making buttons, etc. The finished glove is subjected to a steaming process in a special apparatus.

The other St. Gall firm likewise have about ten machines and maintain forty employees. The output of this firm is about 100,000 dozen pairs a year, most of which are sold for domestic consumption.

During the year 1917 about 1,000,000 dozen pairs of suede cotton gloves were made in the United States, or about five times Switzerland's output in 1918. The industry has also been established in France during the last three or four years, several factories having been started at Grenoble. The textile expert of the French Vice-consulate at St. Gall, who has made a study of this industry, states that France will soon be able not only to produce sufficient for its domestic consumption, but will also be in a position to manufacture for the export trade.

From the fact that this industry has, within the last three or four years, been successfully introduced for various reasons in the United States, France and Switzerland, it would appear that the Chemnitz district which invented and cultivated this industry, has, for the time being at least, lost its monopoly and world control.

NOTES ON BOOKS.

Working Life of Women in the Seventeenth Century. By Alice Clark. London: George Routledge & Sons, Ltd.; New York: E. P. Dutton & Co. 10*s*. 6*d*. net.

With the object of ascertaining what were the circumstances of women's lives in seventeenth-

century England, Miss Alice Clark has, as "Shaw Research Student" of the London School of Economics, made a fairly exhaustive examination of the mass of historical material available for her purpose in the shape of domestic and public records of the period and contemporary literature in which the customs and manners of the day are unconsciously revealed. A list of authorities, occupying some dozen pages, sufficiently indicates the scope of her inquiry.

Her idea, we take it, is to trace the evolution of woman's industrial position under the blight of capitalism, and for this purpose she has chosen a transition period when the woman of affairs is still frequently to be seen side by side with the "lady of leisure," that new product made possible by rapidly increasing wealth, and so amusingly, if unedifyingly, depicted in the pages of the Restoration dramatists. Miss Clark's contribution to social history appears at a time when there is a reaction against the prejudice which excludes woman from public life, and when she is seeking to return, although under different conditions, to the honourable position of economic independence which she appears to have held in considerable measure in the early part of the period under review, and which she was only beginning to lose in the later part of the century. Industry at that time was becoming less and less an affair of the family and the home-work shop (where women could play their part without altogether abandoning household duties) and more and more the concern of wage-paying capital. Chapters are devoted to the aristocratic and *nouveau-riche* classes, to agriculture, to the textile trades, and to the crafts and trades, and in every class of society we find women still leading lives which, for fulness and productivity, compare very favourably with the lives of the majority of women in the first decade of the twentieth century. Idleness, however, was increasing in the wealthier classes, while at the same time in the sweated industries were to be found a large army of poorly-paid unskilled women workers. A chapter on the professions might perhaps have been omitted, as it only goes to show that although women might be particularly suited to be doctors, parsons and lawyers, they were rigidly excluded from these callings as soon as they became properly organised. The lesson which we think emerges clearly from these pages, though insufficient stress is laid on it by Miss Clark, is that woman lost her honourable position in the economic world when changed conditions demanded a specialised training which could not be had in the home. Women either could not or would not be trained. Quite possibly few could be spared altogether from the home, and it therefore seemed natural that facilities should be closed to them for training both in the trades and in the professions. The problem of the surplus woman was not then so urgent.

GENERAL NOTES.

EXPERIMENTS WITH PEANUTS IN MESOPOTAMIA.—An interesting account of a successful experiment which has been carried out at Fellujah, on the River Euphrates, about thirty-eight miles west of Baghdad, with peanuts (or groundnuts) has been furnished by the United States Consul at Baghdad. One of the most remarkable facts about Mesopotamian agriculture is the scarcity of oil seeds among the crops grown in the country. Practically no oil seeds are grown, with the exception of a little sesamum and linseed. In other Oriental countries oil seeds are quite commercial crops. India, for instance, has its linseed, cotton-seed, coconut, gingelly, rapeseed, sesamum and peanuts, while Egypt has its cotton and sesamum, and China its soy beans. Considerable interest, therefore, is attached to an experiment with peanuts carried out at the Fellujah Gardens. The plot was only a small one, about one-tenth of an acre being sown. The crop was sown in June and lifted in November. The person in charge of the garden had no experience of this crop, and sowed somewhat too thickly and overwatered, yet the crop when first lifted gave 2,550 lb. of nuts, which, when dried, gave 1,800 lb. per acre. Peanuts are already in considerable demand in the country, large quantities being imported from India. At present the nut is consumed in a parched state or is used for making sweetmeats. Later on, when the production exceeds this local demand, the surplus will find a ready export as an oil seed. The variety grown at Fellujah is a tight-husked variety, with a very attractive bright-red skin, known as the small Japanese. It was not known in Mesopotamia before, and local merchants who have seen samples have been much interested. It has the advantage of being quick growing, requiring comparatively little water, and being easy to dig. Demonstration plots at various centres were to be arranged for this year by the Agricultural Department, and it should be possible to establish this crop on a commercial scale in a short time.

CELLULOSE FROM ANHINGA FIBRE.—Attention is drawn in the *Bulletin of the Federation of British Industries* to the United States Official Commerce Report of November 15th, dealing with the potentialities of anhinga fibre. Anhinga is a Brazilian plant which is chiefly found along the banks of those rivers of Para whose slow current allows a soft mud bed for its roots. The plant constitutes the raw material from which cellulose, for the manufacture of linen paper, is obtained, and may also, under chemical treatment, be transformed into artificial cotton fibre. Experiments on a large scale were started last year with excellent results, and it is stated that a new process for dissolving the fibres has been discovered, which transforms them into very fine white fibres. These resemble cotton fibre of high quality, but are considered to

be superior to it, inasmuch as the lines of the anhinga fibre are straight and parallel. It is declared that the State of Para is capable of producing 100.000 tons of fibre for export annually, and a mill already in operation has a daily output of 600 kilos. The price of the fibre at Para is between 300 and 350 reis—roughly equivalent to 5*d.* in English currency—per kilo.

A PRODUCTIVE AUSTRALIAN GRASS-TREE.—A recent number of the *Weekly Bulletin* of the Canadian Department of Trade and Commerce contains a description of a species of Australian grass tree known as the "blackboy" tree, which flourishes in most parts of the continent, and especially in Western Australia. The peculiar interest of this tree, which grows to a normal height of from 7 to 10 ft., is the variety of commercial purposes to which it can be put. The tree contains gum in large quantities, and amongst other by-products extracted under treatment are tars (free from harmful acids), tarpaulin dressings, rope and sanitary tars, lacquers (such as Japan black), steam and refrigerating pipe lagging, paint for ironwork that requires stoving at high temperatures, stains, and paints; phenol, benzol and alcohols, coke, potash, and pyrogeneous acid. Although until recently no attempt has been made to utilise the tree commercially, a company has now been formed to extract and market its by-products. Not only have all the articles already enumerated been obtained, but the company also intend to produce dyes, perfumes and formalin, and various kinds of varnishes.

"CONSUTA" PLYWOOD.—Messrs. S. E. Saunders, Ltd., of East Cowes, the well-known builders of air and marine craft, have forwarded to the Society some specimens of their "consuta" plywood. The component layers, after being cemented together, are sewn through with rows of parallel stitching. It is claimed that this process gives to "consuta" a super-added strength and stability which make it the strongest and lightest material yet evolved. It has been used for the last twenty years in the construction of racing motor-boats, gondolas for airships, hulls for flying boats, etc. Hitherto the material has been handsewn, but it has now been found possible to produce the material by machinery and in commercial quantities.

SUGAR-CANE INDUSTRY.—The Kingston (Jamaica) correspondent of the "*Times*" *Trade Supplement* reports that this industry is booming in the largest of our West Indian colonies. "The transformation in some centres is remarkable. Large properties have been brought under cultivation, especially in the central section of the island. Bananas have given way to cane plants; large sugar factories have been erected, two of them being in operation, while a third—the largest central in the island—will be at work early this year." A scheme for the establishment of a Government central factory is under consideration.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday afternoons, at 4.30 p.m.:—

FEBRUARY 11.—LIEUT.-COMMANDER NORMAN WILKINSON, R.N.V.R., O.B.E., R.O.I., R.I., "Naval Camouflage." REAR-ADMIRAL SIR DOUGLAS EGREMONT R. BROWNRIGG, Bt., C.B., will preside.

FEBRUARY 18.—SIDNEY PRESTON, C.I.E., "English Canals and Inland Waterways." NEVILLE CHAMBERLAIN, M.P., will preside.

FEBRUARY 25.—JAMES CURRIE, C.M.G., Ministry of Labour (Training Department), late Principal, Gordon Memorial College, Khartoum, "Industrial Training."

MARCH 3.—WILLIAM JAMES GARNETT, First Secretary, H.B.M. Diplomatic Service, "Mongolia from the Commercial Point of View."

MARCH 10.—H. M. THORNTON, "Gas in relation to Industry and Housing." SIR ROBERT A. HADFIELD, Bt., D.Sc., F.R.S., will preside.

MARCH 17.—WILLIAM WORBY BEAUMONT, M.Inst.C.E., "Street Passenger Transport of London."

MARCH 24.—AIR-COMMODORE EDWARD MAITLAND, C.M.G., D.S.O., A.F.C., "The Commercial Future of Airships."

APRIL 14.—JOSEPH THORP, "The Fundamental Basis of Good Printing."

COLONIAL SECTION.

Tuesday afternoons, at 4.30 p.m.:—

MARCH 2.—G. F. SCOTT ELLIOT, M.A., B.Sc., F.R.G.S., "Trade Routes for the Empire in Africa." COLONEL SIR THOMAS H. HOLDICH, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., will preside.

MAY 4.—PROFESSOR WILLIAM A. BONE, D.Sc., Ph.D., F.R.S., "Lignite."

Dates to be hereafter announced:—

CHARLES H. SHERRILL, "Stained Glass."

GRAILY HEWITT, "Rolls of Honour."

CHARLES CROWTHER, "The Arts and Crafts of Japan" (with examples from the author's private collection).

WILLIAM CRAMP, D.Sc., M.I.E.E., "Pneumatic Convoying Plants, with special reference to the Transport of Grain."

L. GASTER, "Industrial Lighting in its relation to Efficiency."

SIR VALENTINE CHIROL, "The Enduring Power of Hinduism." (Sir George Birdwood Memorial Lecture.)

BRIGADIER-GENERAL LORD MONTAGU OF BEAULIEU, C.S.I., "Roads and Transport in India."

SIR GEORGE CUNNINGHAM BUCHANAN, K.C.I.E., M.Inst.C.E., "The Ports of India: their Administration and Development."

CANTOR LECTURES.

Monday evenings, at 8 p.m.:—

CHARLES FREDERICK CROSS, B.Sc., F.R.S., F.C.S., "Recent Research in Cellulose Industry." Three Lectures.

Syllabus.

LECTURE I.—FEBRUARY 16.—*Compound Celluloses.* (*a*) Lignocelluloses: (1) Jute: Heart damage of baled jute—Bearings on problems of constitution and formation, and on industries—Special treatment of jute and jute fabrics for decorative and "useful" applications; (2) Esparto: As a special type of lignification—New researches; (3) Woods: Lignification and de-lignification—Relations of lignone to their "aromatic" by-products. (*b*) Cutocelluloses, a special chemistry of raffia—The question of natural cellulose esters, and a technical ideal.

WALTER ROSENHAIN, B.A., D.Sc., F.R.S., Superintendent, Department of Metallurgy and Metallurgical Chemistry, National Physical Laboratory, "Aluminium and its Alloys." Three Lectures.

April 12, 19, 26.

ARTHUR THOMAS BOLTON, F.R.I.B.A., F.S.A., Curator, Soane Museum, "The Decoration and Architecture of Robert Adam and Sir John Soane, 1758–1837." Three Lectures.

May 3, 10, 17.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, FEBRUARY 9...British Academy, King's College, Strand, W.C., 5.30 p.m. Ven. Archdeacon Charles, "The Apocalypse." (Lecture II.)

East India Association, 7A, Tothill-street, S.W., 3.45 p.m. Sir Harvey Adamson, "Burma."

Engineers, Society of, at the Geological Society, Burlington House, W., 5.30 p.m. Mr. B. Geen, "Presidential Address."

Geographical Society, Kensington-gore, W., 5 p.m. Captain H. A. Lloyd, "Characteristics of the Ground as Seen from the Air."

Brewing, Institute of, Imperial Hotel, Russell-square, W.C., 8 p.m. Mr. D. Brownlie, "Coal Saving by Scientific Control in the Boiler House."

TUESDAY, FEBRUARY 10... Royal Institution, Albemarle-street, W., 5 p.m. Professor G. Elliot Smith, "The Evolution of Man and the Early History of Civilisation." (Lecture III.)

Civil Engineers, Institution of, Great George-street, S.W., 5.30 p.m. 1. Mr. P. M. Crosthwaite, "Experiments on the Horizontal Pressure of Sand." 2. Dr. A. R. Fulton, "Overturning Moment on Retaining-Walls."

Oriental Studies, School of, Finsbury-circus, E.C., 5 p.m. Mr. A. D. Innes, "The Mogul Period of the History of India." (Lecture I.)

British Decorators, Institute of, Painters' Hall, Little Trinity-lane, E.C., 7.30 p.m. Mr. P. Waterhouse, "Happy Bondage."

Photographic Society, 35, Russell-square, W.C., 7 p.m. Annual General Meeting.

Zoological Society, Regent's Park, N.W., 5.30 p.m. 1. The Secretary, "Report on the Additions made to the Society's Menagerie during the months of November and December, 1919." 2. Mr. R. I. Pocock, "Exhibition of Photographs of a Chinese Serow." 3. Mr. H. R. Hogg, "Some Australian Opiliones." 4. Dr. C. F. Sonntag, "Description of the Larynx and Œsophagus of a Common Macaque, exhibiting several unusual Features." 5. Messrs. R. E. Turner and J. Waterston, "A Revision of the Ichneumonid Genera *Labium* and *Poecilocryptus*."

Colonial Institute, Central Hall, Westminster, S.W., 8 p.m.

WEDNESDAY, FEBRUARY 11...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Mr. N. Wilkinson, "Naval Camouflage."

United Service Institution, Whitehall, S.W., 3 p.m. Colonel F. C. Fuller, "The Tank Corps."

Literature, Royal Society of, 2, Bloomsbury-square, W.C., 5.15 p.m. Professor Sir Henry Newbolt, "English Narrative Poems."

Industrial League and Council, Carpenters' Hall, Throgmorton-avenue, E.C., 5.15 p.m. Right Hon. W. Adamson, "The Industrial Situation."

THURSDAY, FEBRUARY 12...Trained Masseuses, Society of, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 6 p.m.

Royal Society, Burlington House, W., 4.30 p.m.

Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Dyers and Colourists, Society of (Bradford Junior Branch). 1. Mr. H. Robinson, "The Fastness of Gambines." 2. Mr. J. Wraith, "The Finishing of Dress and Coating Fabrics."

Royal Institution, Albemarle-street, W., 3 p.m. Professor A. E. Conrady, "Recent Progress in Applied Optics." (Lecture II.)

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Dr. R. W. Seton-Watson, "The Czecho-Slovak Republic."

Electrical Engineers, Institution of, at the Institution of Civil Engineers, Great George-street, S.W., 6 p.m. Major K. Edgcumbe, "The Protection of Alternating Current Distribution Systems without the use of Special Conductors."

Historical Society, 22, Russell-square, W.C., 5 p.m. Anniversary Meeting.

FRIDAY, FEBRUARY 13...London Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Rev. E. G. O'Donoghue, "The Story of Bethlehem Hospital."

Royal Institution, Albemarle-street, W., 9 p.m. Professor W. M. Bayliss, "The Volume of the Blood and its Significance."

Malacological Society, Burlington House, W., 8 p.m.

University of London, University College, Gower-street, W.C., 5 p.m. Dr. T. Borenius, "Mediæval Art." (Lecture V.)

Astronomical Society, Burlington House, 5 p.m.

Automobile Engineers, Institution of (Graduates' Section), 28, Victoria-street, S.W., 8 p.m. Mr. F. R. Cowell, "Steering Gears."

Physical Society, Imperial College of Science, South Kensington, S.W., 5 p.m. 1. Professor C. H. Lees, Presidential Address. 2. Sir Arthur Schuster, "Atmospheric Refraction during Total Solar Eclipses."

Auctioneers and Estate Agents' Institute, 34, Russell-square, W.C., 7.45 p.m. Mr. J. S. Motion, "Licensed Property."

SATURDAY, FEBRUARY 14...Royal Institution, Albemarle-street, W., 3 p.m. Sir Frank W. Dyson, "The Astronomical Evidence Bearing on Einstein's Theory of Gravitation." (Lecture III.)

Journal of the Royal Society of Arts.

No. 3,508. VOL. LXVIII.

FRIDAY, FEBRUARY 13, 1920.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

MONDAY, FEBRUARY 16th, at 8 p.m. (Cantor Lecture.) Mr. CHARLES FREDERICK CROSS, B.Sc., F.R.S, "Recent Research in Cellulose Industry." (Lecture I.)

WEDNESDAY, FEBRUARY 18th, at 4.30 p.m. (Ordinary Meeting.) SIDNEY PRESTON, C.I.E., "English Canals and Inland Waterways." NEVILLE CHAMBERLAIN, M.P., will preside.

THURSDAY, FEBRUARY 19th, at 3 p.m. Conference on House Furnishings at the Ideal Home Exhibition, Olympia. The RIGHT HON. SIR AUCKLAND GEDDES, K.C.B., M.P., President of the Board of Trade, will preside. (See Notice below.)

Further particulars of the Society's meetings will be found at the end of this number.

CONFERENCE ON HOUSE FURNISHINGS.

The Council have arranged to hold a Conference of Manufacturers and Distributors of House Furnishings and of others specially interested in the subject, in connection with the Ideal Home Exhibition at Olympia on Thursday, February 19th, at 3 p.m.

The chair will be taken by the Right Hon. Sir Auckland Geddes, K.C.B., M.P., President of the Board of Trade; Sir Henry Trueman Wood, Chairman of the Council of the Royal Society of Arts, and Sir Frank Baines, C.B.E., M.V.O., Principal Architect of H.M. Office of Works, will also speak, and thereafter the meeting will be invited to take part in a general discussion.

The main object of the conference is to initiate a scheme whereby the manufacturers and distributors in the different industries concerned may have an opportunity for interchanging views with regard to the development of their trades as to both quality and quantity of production. The Society has already convened conferences of manufacturers and distributors in other industries, as an outcome of which standing committees have been formed which will meet from time to time to discuss questions affecting the interests of the trades concerned. It is believed that these will serve a very useful purpose, and in a similar way it is hoped, after the general conference at Olympia, to hold special conferences of manufacturers and distributors of the various articles used in house furnishing.

Fellows of the Society desiring to attend the conference are requested to communicate with the Secretary, who will be glad to forward to them cards of admission to the Exhibition.

NINTH ORDINARY MEETING.

WEDNESDAY, FEBRUARY 11th, 1920; REAR-ADMIRAL SIR DOUGLAS EGREMONT R. BROWNRIGG, Bt., C.B., Chief Censor, Admiralty, 1914–18, in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Barker, Sir Francis H., London.
Binns, A. S., Winnipeg, Canada.
Bowring, Edward John, Winchfield, Hants.
Cadbury, L. J., Northfield, Birmingham.
Ferguson, Louis, Port Glasgow, N.B.
James, Albert Alfred, J.P., Edgbaston, Birmingham.
Kelman, George Arthur Duff, London.
Mann, G. L. C., West Guildford, West Australia.
Mason, Rev. W. A. Parker, M.A., F.R.Hist.S., Manchester.
Mather, Right Hon. Sir William, LL.D., M.Inst.C.E., Bramshaw, New Forest.
Morris, Wing-Commander Alfred Drummond Warrington, R.A.F., C.M.G., O.B.E., London.
Naylor, Heaton, Rawdon, near Leeds.
Notley, Fenton George, Maclean, New South Wales, Australia.
Phillips, Grevile Herbert, Hereford.
Robinson, Commander Samuel M., U.S. Navy, San Francisco, California, U.S.A.

Rogers, John H., London.
Taylor, Alfred, York.
Thomas, Frank, London.
White, Tyndale, Brentwood, Essex.
Wright, Francis, Vancouver, B.C., Canada.

The following candidates were balloted for and duly elected Fellows of the Society:—

Cameron, Alexander, Sunderland.
Campbell, Archibald Jack, Dalmuir, Scotland.
Subedar, Ardeshir Rustumji, Bombay, India.

A paper on "The Dazzle Painting of Ships" was read by LIEUT.-COMMANDER NORMAN WILKINSON, R.N.V.R., O.B.E., R.O.I., R.I.

The paper and discussion will be published in a subsequent number of the *Journal.*

PROCEEDINGS OF THE SOCIETY.

EIGHTH ORDINARY MEETING.

WEDNESDAY, FEBRUARY 4th, 1920; SIR EDWARD W. BRABROOK, C.B., F.S.A., in the chair.

The paper read was:—

THE ENGLISH LANGUAGE AND INTERNATIONAL TRADE.

By ALFRED E. HAYES,

General Secretary, English Language Union.

If there is at this moment one human aspiration more universal than any other it is the eager hope that humanity may escape as quickly and as safely as possible from an age of chaotic conflict and waste into a new era of co-operative economy and social and international goodwill. If there is one conviction which the great world-war has driven deep into the hearts and minds of men it is that an essential unity of interest governs the relations of humanity.

In his Raleigh Lecture on "World History," delivered before the British Academy last October, Lord Bryce thus justified his topic: "The subject seems not unfitted to that strange phase, critical beyond all precedent, through which we, with the other civilised nations, have been passing. For the first time in the annals of our planet its inhabitants have become one whole, a community each and every part of which is affected by the fortunes of every other part . . . many forces, non-political even more than political . . . had been drawing the nations together. But it was the outbreak of war that first made us realise how mankind had virtually become one community, all the members whereof were to be thereafter linked together. Except as respects the loss of their citizens in war and the devastation of their territories, some of the neutral nations suffered, and some are indeed still suffering, almost as much as the belligerents. There followed a phenomenon rarely noted before, a formidable rise in prices, with a corresponding rise in wages, in every civilised country. The contagion of excitement and of strange doctrines accepted under excitement has spread far and wide. Thus have all men been forced to feel that the parts of the world have grown into one, for weal or for woe; thus comes it that now for the first time the history of the world in the full sense of the word can begin to be written."

Lord Bryce went on to specify and to examine, with characteristic catholicity and clarity, the "processes and the forces whereby races, tribes, nations and states have been, or are being, drawn together into one common life commensurate with the earth which they inhabit." Of these forces and influences he named three as supremely active—Conquest, Commerce and Religion—and touched tentatively upon "a new force which might, if brought into effective play, profoundly modify the relations of peoples to one another . . . the uniting into one body all over the world . . . of the hand-workers, or so-called 'proletariate.'" Of the unifying influence of philosophy, literature, physical science, and other related forces, Lord Bryce deemed it needless to speak to such an audience as the British Academy, and hazarded the prediction that some centuries hence ten languages may be spoken by more than nineteen-twentieths of mankind.

It would be an interesting task to attempt to estimate in what relative degrees the forces referred to by Lord Bryce have been responsible for the present geographical distribution of languages. Discovery, conquest, commerce and religion have all played their parts, concurrently or sequentially, in fixing the speech-areas of the world. In the two Americas, in the greater part of Africa, in Northern Asia, in Australasia and the Pacific Isles, discovery led the way for missionary zeal, for settlement and for conquest, while commerce followed in their train. In India trade opened the gates to conquest and the unifying influences of the British domination. In China and Japan commerce, calling in the aid of arms, broke through the barred and bolted doors that had for centuries shut in their teeming millions from contact with the Western world.

If discovery and conquest have coloured the

language-map over vast but thinly-peopled regions of the earth it is the more permeative influence of the personal contact of the trader, and of the missionary of religion, philosophy, science or education—served in these later days by almost miraculous and constantly advancing means of transport, transit and communication —that has broken down, and is daily breaking down, with cumulative energy, the barriers of racial, national and linguistic isolation, alike in the old world and the new.

And if the Briton has, in the past, played a master-part in these processes, it is due to those national characteristics of which Emerson wrote with such luminous sympathy in Victorian days—to that happy combination of physical vigour and mental complexity which have made him so pregnant a paradox in the history of the race. His constitutional vitality, bred and braced by a boisterous climate, has driven him to and through the waste spaces of the earth. His Celtic, Teutonic and Latin ancestry has woven for him a cerebral texture which, while displaying apparent contradictions and seeming insincerities very confusing to the foreigner of more homogeneous heredity, has not infrequently given him that combination of robust intellectual independence and catholic sympathy, that union of imagination and capacity, that practical idealism, which have, at so many stages in our history, championed the cause of human freedom, and inspired and guided those political and social adaptations to which the progress of ordered liberty owes so much.

It is to this peculiar quality of universal appeal and application that so many voluntary world-wide organisations, striking easy root in widely-differing nations, owe their birth in these islands.

I refer to this phenomenon not in any spirit of national egotism but to emphasise the fact that the world-wide influence of our people is not entirely due to Machiavellian diplomacy, and to discount in advance the criticism that any efforts we may put forth in the future to extend the use of the English tongue are due, not to a spirit of world-service, but to deep-laid plans for political preponderance and commercial advantage. The supremacy of the French language in diplomacy and of the English tongue in trade is due to no direct action on their behalf, but is merely the accidental accompaniment of the operations of the national character and genius in their special fields.

Indeed, it is precisely these two nations which have given the most hospitable reception and the most enthusiastic advocacy to those artificial languages which, since the era of maritime discovery and the intellectual renascence, have sought in swift succession to meet the world's need for a common speech. It was an English bishop and phonetician, John Wilkins, who in 1668 constructed the first of the so-called "philosophic" languages; and the most comprehensive history of all these efforts, combined with the most brilliant and powerful plea for this "artificial" solution of the problem, is the work of two Frenchmen, MM. Couturat and Leau. It is in England and France that Esperanto finds its most numerous adherents.

I cannot here enter into a full discussion of the rival claims of "artificial" and "living" tongues. I agree with M. Paul Passy, who, in reply to a correspondent, Mons. Clédat, wrote some years ago in *Le Maitre Phonétique*, the organ of the International Phonetic Association: "As for us, we shall show that the international language ought to be a 'living' language; the problem becomes more and more circumscribed and its solution approaches." Over seventy artificial languages have been thrust upon the notice of the world since John Wilkins' day. It has been a mournful waste of energy. Every such language yet constructed has been rapidly followed by others claiming superior merit. Zahmenoff's Esperanto was born in 1887. It has at least ten later rivals, and, although it has been "boomed" with a lavish expenditure of energy and money its users all the world over would not displace the population of a London borough. The solution certainly approaches, but it will be a solution in accord with hard facts. Quite apart from the populations of the English-speaking lands, with their opportunities for vast expansion, for every foreigner who can be converted to the use of Esperanto many thousands are born who, under the pressure of commercial necessity or the spur of cultural ambition, will learn the English tongue. Yet, while the neglect of the study of English in our universities and schools is a by-word and a reproach, British educational authorities are spending public money at the bidding of a handful of misguided fanatics on this doomed futility of an artificial speech. As for fostering the study of English abroad, as Mr. H. G. Wells has said in his "Anticipations," "There is no sign that either the English or the Americans have a sufficient sense of the importance of linguistic predominance in the future of their race to interfere with natural

processes in this matter for many years to come." It is among foreigners that one finds the greatest interest in English as a world-speech. Quite recently the Board of the Peace Congress of the North reported that in reply to its inquiry twelve out of nineteen university professors were opposed to any artificial language, and voted for English as the International tongue. Of the remainder, two were for French, one for German, one for Esperanto, and three for Ido.

A far more important plebiscite was conducted in 1903 by Mr. Gudmund Schütte, the Danish editor of the *Godlansk Budstikke*, and I was present at the meeting of the Teutonic Philology Society in Copenhagen at which the results of the inquiry were declared and discussed. I have before me the full list of the votes cast, and they show an overwhelming majority in favour of English, and include not only the names of distinguished authors, editors, publicists and traders, but professors and teachers of German, French and other languages. In the case of the greater nations the major pressure in favour of English is commercial, but with the smaller nations some such choice is in addition an intellectual necessity. Mr. Wells has well described their dilemma in his chapter on "The Conflict of Languages" in that volume of predictions to which I have already referred. He says: "The native of a small country who knows no other language than the tongue of his country becomes increasingly at a disadvantage in comparison with the user of any of the great languages of the Europeanised world. For his literature he depends on the scanty writers who are in his own case and write, or have written, in his own tongue. Necessarily they are few because necessarily with a small public there can be only small subsistence for a few. For his science he is in a worse case. His country can produce neither teachers nor discoverers to compare with the numbers of such workers in the larger areas, and it will neither pay them to write original matter for his instruction nor to translate what has been written in other tongues . . . In the matter of current intelligence the case of the speaker of the small language is still worse. His newspaper will need to be cheaply served, his home intelligence will be cut and restricted, his foreign news belated and second-hand. Moreover, to travel even a little distance, or to conduct anything but the smallest business enterprise, will be exceptionally inconvenient to him. The Englishman who knows no language but his own may travel well-nigh all over the world and everywhere meet someone who can speak his tongue. But what of the Welsh-speaking Welshman? What of the Basque and the Lithuanian who can speak only his mother tongue? Everywhere such a man is a foreigner, and with all the foreigner's disadvantages. In most places he is for all practical purposes deaf and dumb. The inducements to an Englishman, Frenchman or German to become bilingual are great enough nowadays, but the inducements to a speaker of the smaller languages are rapidly approaching compulsion. He must do it in self-defence. To be an educated man in his own vernacular has become an impossibility. He must either become a mental subject of one of the greater languages or sink to the intellectual status of a peasant."

The bogey of international jealousy which is so often stuck up by the advocates of an artificial *lingua-franca* to deter the English-speaking peoples from their plain duty derives no support from the nations whose susceptibilities they so tenderly consider. If one desires to find evidences of language-jealousy one must seek the bitterest examples among the rival supporters of artificial tongues. All serious testimony goes to show that personal advantage or intellectual interests decide the choice of language-study without regard to patriotic sentiment. "The action of the force of attraction of the great tongues is cumulative. It goes on, as bodies fall, with a steady acceleration." In the case of English it is becoming day by day more irresistible. National sentiment did not deter Bismarck from opening in English the Berlin Congress of 1878, nor the British and American representatives from speaking French at the recent Peace Conference in Paris. Practical utility alone will guide the choice of an international speech, and every day brings fresh proof that the choice is virtually no longer in doubt. Mr. Barnes, the representative of the British Government at the International Labour Conference at Washington, the most important industrial gathering ever held in the world's history, tells us in the *Observer* that "a remarkable feature of the Conference was the extent to which English was spoken by the delegates. In the case of India, Japan, China, Siam and Persia, all their delegates spoke English, many of them fluently. This simplified proceedings immensely. There was no language difficulty, so to speak. French and English were the two official languages, and only one delegate, an Italian Workers' representative, used his native tongue. This widespread know-

ledge and use of English is a hopeful sign that our language is becoming the diplomatic as well as the commercial language of the world."

There is no need here to emphasise the place which the study and use of English occupies in India and the Far East. Mr. Hartog's brilliant survey of Indian education in his recent paper read before this Society adequately presents the facts and points the moral. In Japan there has been for some years a large and influential English Language Association, composed mainly of teachers and presided over by Professor Okakura. In China, where English has been for so long the language of international trade, there has lately been a large extension of compulsory English in the schools. Of Scandinavia I shall speak in greater detail later on. Coming nearer home, in Holland a group of teachers has formed a "Peace by English League," whose objects are declared to be "to make the English language the world language, read by every civilised man and used for all correspondence." In Belgium Dr. Charles Didier has founded, under the highest auspices, an "English-speaking Association," which advocates the adoption of English as "the auxiliary language for all Belgians."

Even from Germany comes the same decision and demand. In the November-December issue of *Die Frau im Staat*, a monthly journal published in Munich, Hellmuth von Gerlach writes:—

"In my youth the first world language, 'Volapük,' was produced by the Swiss Schreyer. The idea interested me keenly; I ordered his text-book and commenced with pleasure, since one could master the rudiments of this language in a few days. However, I did not arrive at any practical use of it since it held little interest as a world language.

"Volapük is long since forgotten. I began to get theoretically interested in Esperanto and I soon decided to commence its study. Then Püus (Reichstagsabgeordneter) assured me that 'Esperanto has been superseded by Ido! Ido is the only world language. Learn Ido!'

"Most people do not realise the importance of a world language, whether it be Esperanto or Ido or Esperantido. To have a number of world languages is absolute madness.

"The world-language movement has gained new meaning through the Völkerbund (League of Nations). For the first time in the history of the world a real centralisation of the peoples has been conceived; although only in embryo something may come of it. One of the tasks of this centralising of the peoples will be a medium of understanding for all nations. Whoever thinks anything about the International Congress knows the importance of a commercial language. Where there are only educated people it is immaterial which of three or four languages be used, but this is a rare exception. Almost invariably translations follow; these hinder the progress of commerce and often bring failure in their wake.

"We need an international language! The question only is, which shall it be?

"I maintain that it is superfluous to create a world language. Under the ægis of a League of Nations it would be better to choose one of the existing languages. This language should be obligatory in all the higher and middle schools in the world.

"The language which seems to me most worthy of consideration on practical grounds is English. It has developed of itself, so to speak, into a world language, in the form of 'pidgin' English. It means much to the traveller to be able to make himself understood by the natives in 'pidgin' English as well in Eastern Asia as in Africa.

"When going to West Africa in 1912 I learnt out of hand the elements of 'pidgin' English in two hours. For those who know English it is mere child's play—200 words, partly good English, partly corrupted, without either conjugation or declension; but quite a raw, clear, comprehensible language. Among all the countless negro tribes, each of which has its own language, one can always find a couple of natives who were once on the Coast and there learnt 'pidgin.' I could use it equally well in the English or German Colonies.

"A supplemented 'pidgin,' or, what is the same, a simplified English, would be the ideal world language. No language with literary ambitions. For Heaven's sake no seeking after an 'artistic' world language! No, exclusively a practical medium of understanding. Pure utility must decide, the 'æsthetic' to be put aside.

"Our England haters, there is a sufficient number of them, will cry 'Zeter' and 'Mordio' at my project. If we want to emerge from the wreckage we must bar all sentiment and work out our policy with cool heads.

"Perhaps internationally-thinking Germans will oppose the 'sacrifice.'

"But the sacrifice is not greater for us than for the Italians, Spaniards, Danes, Russians and French. Especially the French! Even up to to-day it is the diplomatic language and the world speech of statesmen. It would mean a sort of dethronement for the French if the League chose English as the medium of understanding. I know how hard it would be for the French to resolve upon the sacrifice. They love, and rightly so, their language, which was chosen above all others as the politically æsthetic one.

"Yet, I demand the sacrifice even of the French! Practical points of view alone will have to decide.

"Not because English stands higher than other languages has it the birthright as a common language. No, but because through the needs of life itself has it become the medium of understanding in the greater part of the world.

"No one can contest the right to the mother language more keenly than I. It is our sacred kingdom of pure gold. But all peoples need an international medium of understanding, and this should be the English language."

Of the eagerness of our other late enemies, the Bulgarians, to displace German educational leadership by British, Captain Harold Goad gave us an excitingly eloquent account in the *Fortnightly Review* of November last. From this I cannot forbear to quote, if only for the lesson it conveys of the immense importance of a definite abandonment of our national attitude of indifference to the fortunes of our language. He says, in support of his plea for the establishment of British institutes in the Balkan countries :—

"The next question, then, is to consider what channels for the diffusion of English ideals and English teaching could be most effectively adopted. As an example, let us consider the case of Sofia, where I was stationed with the Allied troops of occupation from November until July, with every opportunity of studying the educational and social conditions of the Bulgarian people.

"When we arrived the town was full of German books, and almost every educated person spoke and read German. German culture and German ideals were for most Bulgarians their only conceptions of European civilisation. History, art, literature, drama, were widely studied with characteristic earnestness for self-improvement; but German text-books almost exclusively were used. Nevertheless, it was obvious to all that closer acquaintance with German militarism during the previous two or three years had caused the great majority of Bulgarians to loathe the arrogance of the German soldiery, while the prestige of the German system has collapsed with its defeat.

"The French staff immediately set about importing into the country French literature and French ideals. A Hachette library was established and the Bulgarian branch of the "Alliance Française" was revived, under whose auspices an excellent review was founded, and lectures in French upon the French language and literature were given periodically.

"Judging by the few I attended, these lectures were extremely popular; they were held in the great concert hall of the Bulgarian Officers' Club, which was crowded with all the best-known people of Sofia.

"In the month of May the 'English Speaking League' of Sofia was resuscitated by Bulgarian initiative. At its first meeting, I am told, there were only some four or five Bulgarian ladies present; but undaunted by the smallness of their numbers, these apostles of English culture resolved to hire a fair-sized house as the meeting-place of the league, and to announce in the newspapers the next meeting for a fortnight later.

"At this meeting there were, I suppose, a hundred people present, all conversing together in English, the great majority being old pupils of Robert College at Constantinople. They were all immensely keen on making the league a success. They agreed that the first requisite was a library of English books—literature, history, and the best fiction. They agreed that there ought to be courses of lessons in English, and lectures on the British Empire, and on English life and literature. They thought that the institute should be modelled on the 'Alliance Française,' and were sure that the similar German societies would be re-opened as soon as circumstances would permit.

"Surely, if such is the desire of Sofia, the capital of a defeated enemy, to know more of England, that of our Allies of Belgrade, Athens, Bukarest, and Salonika, could be no less great."

Captain Goad quotes in the same article the appeal of Professor Guido Ferrando and his Italian and English associates for further support for the British Institute in Florence, which has done so much during the war to promote understanding and friendship between the two nations. Captain Goad's vigorous and quite moving advocacy of the establishment of British institutes in Southern and Eastern Europe raises the whole question of how we may, with the greatest economy and efficiency, promote the study of English abroad.

The desirability of establishing British institutes in foreign countries was first suggested to me fourteen years ago by Mr. Sophus Madsen-Mygdal, headmaster of the large boarding-school in West Jutland at which was held the first Danish State's Holiday Course in English, to which I shall presently refer. Mr. Madsen-Mygdal, impressed by the result of our experiment, proposed the foundation of a permanent institute at some attractive centre, staffed and equipped for the continuous and developed application of the methods we had found so successful. I did not then think the time ripe for so adventurous an enterprise, and the matter dropped. I have since regretted it. As a result of the awakening effects of the war similar suggestions have emanated from highly authoritative quarters. Last January Dr. Gardner, in the absence of Professor Sir Bernard Pares at Vladivostock, read a paper by the latter at the Educational Conference which took place last January under the auspices of the Russo-British Bratsvo (1917), over which Sir Paul Vinogradoff presided. In his memorandum Professor Pares propounded a somewhat elaborate and rather costly scheme for the establishment of a British institute at Moscow. Sir Bernard estimated the foundation cost at £20,000, and proposed that the British Government should find most

of the money. In support of his scheme Sir Bernard said: "I am deeply convinced that the answer to German propaganda by intrigue is British propaganda by education. This is a fact which has impressed itself far more strongly on Russian public men than is realised in England. As Germany has broken down Russia, it will be our task, more than that of any other country, to build her up. This is not only a primary interest to us as desiring no territory and no domination in Russia, and not wishing that of any other Power; it is a task which is devolved upon us by Russian instincts which turn to us for models in the creation of a people's Russia, to our political past, to the broad line of our literature and education, and to our principles of commercial exchange; and, unlike other foreign influences, the success of British activity in Russia will be as great in the country districts as in the town. For these reasons there will sooner or later be a fine and self-rewarding career open to Englishmen familiar with the detail of social and educational questions, in the service of a free Russia; and such work will be the more effective service to British influence there. In particular, in the history of peoples, the English possess a record of free self-development such as Germany does not possess, and will certainly be called upon to supply models to Russia; and I therefore, as from the outset, desire to associate closely with the work of the Workers' Educational Association."

The institutes suggested by Captain Goad are of a much less ambitious character than that proposed for Moscow by Professor Pares, and would cost, according to his estimate, only about £2,000 to establish. We have to remember, however, that the utility and influence of an institute fixed in one centre must necessarily be largely limited to the locality, and valuable as such centres might become my own experience inclines me to the view that the money would be more fruitfully employed in more fluid arrangements: that an institute is more in the nature of a superstructure than a foundation. It seems to me to be more necessary at this juncture to stimulate and assist the study of English over wide areas through the ordinary educational machinery of the country than to establish centres of specialised or academic scholarship. There exist in every country varying numbers of persons already engaged privately or officially in teaching English. If these teachers could be brought together in voluntary association they would be able to determine and demand exactly that form of assistance of most immediate service. They would also exercise a formidable collective influence on public interest in their work and its significance, and pave the way for official administrative advance. Institutes, elementary and academic, would then spontaneously arise from natural necessity, and would be of indigenous origin and character.

For such spade-work as I suggest a "Travelling Scholar" appears to me to be the most economical and effective. And he would not only be a propagandist for English abroad but he would return to his own country with a knowledge of and sympathy for the people among whom he had been living—an interpreter of them to his fellow countrymen, of incalculable value to the cause of international understanding and co-operative goodwill. Will you forgive me if, moved, not by egotism but by a simple desire to convince, I indulge in a personal narrative? I regret that I must draw my illustration from my own experience, but I shall hope for your charitable interpretation.

It is now nearly fifteen years ago since I made the first definite attempt to create an English Language Union, which should render to our own world-wide tongue similar service to that enjoyed by the French language through "L'Alliance Française," and "German" from the German Language Association.

That attempt arose from an apparently accidental incident. In 1903 I was sent out as a "Travelling Scholar," by the London School Authority, to make a year's study of Danish education. Soon after my arrival I interested myself in the teaching of English in the schools, going into the class-rooms, giving lessons, talking and reading with the scholars, and giving the teachers what information and advice I could to assist them in their work. I found that this practice immensely stimulated the interest of the pupils in their study of the language. I also inquired into the methods adopted by the Danish Government to assist their teachers of the language to keep themselves fresh and up-to-date. I found that the Danish Rigsdag made quite generous provision to enable a certain number of teachers to visit England for about a month. But there was at that time practically no organised help on this side, and too frequently these visits were of very limited value. I wrote to Dr. (now Sir Frank) Heath, then at the head of the Board of Education's Office of Inquiries and Reports, making certain suggestions for the better reception and assistance of these in-coming foreign

students; and, although my plans were not followed in their entirety, Dr. Heath's action led to the establishment by the London University of its present Summer Courses in English for foreigners.

My interest in the teaching of English in Denmark reached the ears of Professor Rönning, Chief Inspector of the Danish Middle and "Real" Schools. He asked for a conference, and we met at Tarm "Real" School in the west of Jutland. There he made the suggestion which, more than anything else, lies at the root of the admitted success of the Danish State's Summer Holiday Courses in English. Professor Rönning's idea was that it would be a cheap and effective plan to assemble in a large boarding-school in Denmark about twenty-five Danish teachers of English, and to bring over to them a small English staff. Staff and students could live a communal life, rigidly excluding the use of the Danish language, studying, eating, and playing together, and enjoying the close intimacy and mutual helpfulness of a large family. He asked me to draw up a scheme for such a course, and to direct it if a grant could be obtained for the purpose. The interest of the Minister of Education (His Excellency J. C. Christensen, afterwards Prime Minister) was secured, a temporary and experimental grant was voted by the Rigsdag, and I was commissioned to appoint an English staff and to lead the course.

The experiment was carried out in the summer holidays of 1904. Twenty-five teachers of both sexes were selected by Professor Rönning to be the first students, and there were distinguished educationists as guests. Before the course closed the students sent an enthusiastic telegram of thanks to the Minister of Education for the privilege he had given them. The Rigsdag unhesitatingly voted the money every Budget until the outbreak of the Great War. In the third year, at the instance of Professor Jespersen, the grant was doubled to enable the teachers of English in the Gymnasier (Higher, Secondary and Public Schools) to have a course on the same model. The next year the teachers of German demanded a course on similar lines. The Rigsdag voted a grant for a German Course every alternate year —ours remaining annual. The State's Course has, during the ten years of its existence, completely justified itself in the opinion of the Danish authorities and people. It has been visited by experts from Russia, Norway, Sweden and Finland.

Very early during the first course I realised its immense value as a means of influencing Danish opinion respecting Britain. English is compulsory in all the secondary schools, and is taught in some of the primary and continuation schools of the capital and important seaports. Every scholar spends several hours a week with his "English" teacher. These boys and girls are, in a few years, the men and women of the best educated, most articulate and most influential sections of the community. The dynamic enthusiasms born at our course are conveyed day by day, year after year, to succeeding generations of the upper and middle-class youth throughout the whole country. And youth takes its magic home!

From the moment that I recognised the efficiency of this instrument for the promotion of international goodwill, I gave solicitous attention to the factor of personality in the selection of my colleagues, and I here register my deep gratitude for their splendidly capable, sympathetic and devoted service—service which has built up for this course a unique tradition, full of mutual international affection and esteem. Every list of lectures, every item of our daily programme, was considered and reconsidered, so that the very utmost might be done to render to the Danish and the British peoples the utmost mutual service—to remove misconceptions and misunderstandings, to modify opinions and to stimulate goodwill.

The State students have themselves created —and themselves manage—an Old Students' Association, which keeps up the old spirit of affectionate comradeship. It holds an annual meeting and festival in Copenhagen.

It is practically an English Language Association in Denmark. It forms English Study Circles, and links them up for mutual help. The result is that there are now, in over one hundred towns and hamlets scattered throughout Denmark, centres of English culture and influence.

The Old Students have also formed a Circulating Library of English Publications, available for every member for the mere postage.

The cost of the course falls entirely upon Denmark, and was before the war a trifle of about £200 a year. Not a penny of money nor an ounce of influence has been contributed by this country.

This work is not temporary and fugitive. It is permanent and cumulative. It is native in its origin, growth and control. It is purely

educational, and is absolutely free from any other aims than those herein expressed.

Is it to be wondered at that, perceiving its potency, I should return from this course filled with a vision of a great English Language Union, establishing such organisations in every foreign State, and using the world-wide knowledge of our tongue as a means of bringing the nations together in a spirit of friendly, fruitful mutuality?

But no efforts that I could make through ten long years availed to break down the indifference of either the public official or the private citizen to the splendid possibilities that seemed to me so clear and so inspiring.

Then came the Great War, and that unparalleled catastrophe shook the minds of men out of the deadly apathy of years.

The insidious and unscrupulous propaganda of Germany, the revelations of her "peaceful penetration" for aggressive ends shocked the nerves of every nation. Now I felt the time had at last arrived when something might be done. I submitted my plans to the British Government, to Foreign Embassies and Legations, to Anglo-Foreign Societies, to University professors, etc., and in each and every instance the methods and principles of the work carried on for so long in Denmark were cordially approved. Thus have been laid the foundations of the English Language Union, a union which, if adequately supported, may repeat the story I have just related in every country in the world to the immense advantage both of international understanding and international trade.

Mr. H. G. Wells, in his book "The World Set Free," predicts, you will remember, the outbreak of a great world-war a generation later than it has actually occurred, and gives us his equivalent of the League of Nations in the Council of Brissago. It is interesting to read now his prophecy of the adoption of the English language as the world-speech and the subsidiary changes which accompanied it. He says:—

"It is characteristic of the manner in which large enterprises forced themselves upon the Brissago Council that it was not until the end of the first year of their administration, and then only with extreme reluctance, that they would take up the manifest need for a *lingua-franca* for the world. They seem to have given little attention to the various theoretical universal languages which were proposed to them. They wished to give as little trouble to hasty and simple people as possible, and the world-wide distribution of English gave them a bias for it from the beginning. The extreme simplicity of its grammar was also in its favour.

"It was not without some sacrifices that the English-speaking peoples were permitted the satisfaction of hearing their speech used universally. The language was shorn of a number of grammatical peculiarities. The distinctive forms for the subjunctive mood, for example, and most of its irregular plurals were abolished; its spelling was systematised and adapted to the vowel sounds in use upon the Continent of Europe, and a process of incorporating foreign nouns and verbs commenced that speedily reached enormous proportions. Within ten years from the establishment of the World Republic, the New English Dictionary had swelled to include a vocabulary of 250,000 words, and a man of 1900 would have found considerable difficulty in reading an ordinary newspaper. On the other hand, the men of the time could still appreciate the older English literature . . . Certain minor acts of uniformity accompanied this larger one. The idea of a common understanding and a general simplification of intercourse, once it was accepted, led very naturally to the universal establishment of the metric system of weights and measures, and to the disappearance of the various makeshift calendars that had hitherto confused chronology. The year was divided into thirteen months of four weeks each, and New Year's Day and Leap Year's Day were made holidays, and did not count at all in the ordinary week. So the weeks and the months were brought into correspondence. And moreover, as the king put it to Firmin, it was decided to 'nail down Easter.' . . . In these matters, as in so many matters, the new civilisation came as a simplification of ancient complications; the history of the calendar throughout the world is a history of inadequate adjustments, of attempts to fix seed-time and harvest that go back into the very beginning of human society; and this final rectification had a symbolic value quite beyond its practical convenience. But the Council would have no rash nor harsh innovations; no strange names for the months, and no alteration in the numbering of the years.

"The world had already been put upon one universal money basis. For some months after the accession of the Council the world's affairs had been carried on without any sound currency at all. Over great regions money was still in use, but with the most extravagant variations in price and the most disconcerting fluctuations of public confidence. The ancient rarity of gold upon which the entire system rested was gone. Gold was now a waste product in the release of atomic energy, and it was plain that no metal could be the basis of the monetary system again. Henceforth all coins must be token coins. Yet the whole world was accustomed to metallic money, and a vast proportion of existing human relationships had grown up upon a cash basis, and were almost inconceivable without that convenient liquidating factor. It seemed absolutely necessary to the life of the social organisation to have some sort of currency, and the Council therefore had to discover

some real value upon which to rest it. Various such apparently stable values as land and work were considered. Ultimately the Government, which was now in possession of most of the supplies of energy-releasing material, fixed a certain number of units of energy as the value of a gold sovereign, declared a sovereign to be the exact equivalent of twenty marks, twenty-five francs, five dollars, and so forth with the other current units of the world, and undertook, under various qualifications and conditions, to deliver energy upon demand as payment for every sovereign presented. On the whole this worked satisfactorily. They saved the face of the pound sterling. Coin was rehabilitated, and, after the phase of price fluctuations, began to settle down to definite equivalents with the names and everyday values familiar to the common run of people."

Whether we agree or not with all Mr. Wells's predictions, we can make quite sure that the world-use of the English tongue will bring results of vast importance to industry and commerce. It will mean the pooling of the brains of the world, the cheap and universal distribution of the best thought, the most expert processes. It will eliminate the time, energy, accommodation and material now used up in the waste work of translation. It will speed up business transactions, and minimise the risks of misunderstandings. It will seriously affect all the labour involved in the direct and accessory arts and crafts of book production. It will revolutionise the art and scope of advertising. It will make easy the employment of alien direction or alien craftsmanship where special needs call for it. It will modify business manners and customs, and change the whole character of commercial education.

Many of these changes are still "the music of the future," and we may safely desert their contemplation for the moment for the more immediate study of the intimate relationship which exists between international intellectual sympathy and international industry and commerce. I was much struck during my mission to Norway last spring by the fact that while the vast majority of the people sympathised with the Allies, the greater number of the academicians and "intellectuals" did not share this partiality. The Germans have never made the mistake of turning the cold shoulder to foreign scholars and students who have desired to share their educational advantages. On the contrary, they have welcomed them with open arms, confident that they would return to their own countries convinced that Germany was the repository of all that was best in scholarship, art, science, and industry. The folly of our over-modesty in this direction is plainly put in the Memorandum on Educational Propaganda in Russia to which I have before referred. I quote the following:—

"At the present time the only Readers for Russians who desire to learn English are the German publications of the firm of Mannstein in Riga. Apart from the fact that it is not to the advantage of British interests that the English language should be taught through the medium of German text-books, these editions are now unobtainable. There is, therefore, a demand for a carefully and attractively edited series of graduated Readers with English-Russian vocabulary and Russian notes.

"The demand for information on British universities opens up another series of very important publications. A book on the provision made for technical education in England is badly needed; and in order to convince the more sceptical, who have been taught to look on German methods as the *ne plus ultra* of the student's aspirations, it is highly advisable that such a work should be more detailed and elaborate than the scope of the series might seem to render necessary; for it must be remembered that Russian technical students know nothing whatever about technical study in England, which their ignorance inclines them to regard with contempt, while they are none the less attracted by detailed descriptions supplemented by suitable illustrations and diagrams.

"The libraries of the Russian technical institutes are not provided with representative English sections. It is therefore important, as a valuable form of propaganda, that a complete and representative section of British technical books should be presented to the leading Russian institutes as soon as conditions make this possible, and that these institutes should be supplied with the latest British publications which are regarded by British experts in the various subjects as being representative contributions of British scholarship to the knowledge of the particular branch of technical science.

"In considering the technical training of Russians, it is very important that a supply of machinery should follow as early as possible after British propaganda as to our technical resources. The British Consul at Baku stated in a letter to me that wherever a new technical school was to be opened in any town of Russia, German commercial travellers invariably appeared and took orders for the supply of technical equipment within six months. The Consul further remarked that technical workers who have become accustomed to given machinery in their student days later retained a fixed preference for this kind of machinery. The supply of British machinery to Russian technical institutes therefore becomes of capital importance."

May I here venture to say that so long as foreign book-shops display only the comparatively worthless products of our press, so long as English publishers pursue their short-sighted

policy of producing only books that are "popular," so long as Mr. Wells's bitter strictures on the production of books in English hold good—and they still do—so long will the best products of British brains remain little known abroad, to the immense disadvantage of all concerned. In this connection let me draw attention to an article by Professor Biagi in the "Vita Britannica," in which he tells us that in the year 1918 the total importation of English books and newspapers into Italy amounted to less than 70 tons, valued at about £14,000, while the importation of German books and publications was over 360 tons, valued at about £70,000, "and this latter," he says, "was not mere merchandise to be weighed in tons and hundredweights. It was rather so much poison-gas, that, little by little, saturated with Germanism places where it was received as an illuminant; it intoxicated men's minds and poisoned their consciences. Of all imports it was the most dangerous and deleterious, and we have found everywhere in Italy its evil effects."

Another reform which must be carried through if we are to make easy the world-use of English is a simplification of our wretched orthography. It is a most serious hindrance to the foreigner, and is, indeed, the one valid criticism that can be brought against the choice of English as the international speech. Into this highly controversial field I may not now enter. I can only emphasise the urgent necessity for some swift and practical solution of the problem.

I conclude this very inadequate treatment of a great subject with a sincere appeal to the enlightened patriotism of the English-speaking world.

We have hitherto strangely neglected our duty to our tongue. We have looked on indifferently when other nations, with a keener perception of national advantage, have energetically encouraged and supported the foreign study of their mother tongues. "L'Alliance Française" has been long at work, and a Portuguese journal, *A Lucta*, examining, in 1917, the influence of Germany's policy of endowing German schools abroad, saw in it one of the main causes of German success. Italian authorities and business corporations are making every effort to extend the study of their tongue here and elsewhere, and many of the newly-formed Anglo-Foreign Societies are energetically pursuing similar aims.

Provided it is done in no spirit of national aggression, this is all to the general good. No nation can be thoroughly understood except through the medium of its own speech. You cannot translate the soul of a people. Every student of a foreign language is adding a stone to the temple of international understanding. It is the imperative duty of every nation to contribute its share to the great synthesis of a unified humanity.

The great English-speaking democracies must not shirk their obligations to the world. The English language is more widely spoken than any other. More than half the newspapers, magazines and books of the world are printed in the English tongue. Long ago, the great German philologist, Grimm, declared that "the English language, as used by Shakespeare, can rightfully be called a world-language, and seems, like the English people itself, destined in the future in yet greater measure than heretofore to rule in all the ends of the earth. When we consider its richness, intellectuality and condensed adaptability, no one of all the other living languages may be placed at its side; yea, not even our own German language, which is torn even as we are torn."

It is not our business to thrust our language upon other nations. Aggressiveness always defeats its own ends. But we ought not to stand indifferently aloof when foreign students need our friendly help in their endeavours to win the key to the life and thought of the English-speaking world.

In the far-distant future, when empires have lost their meaning and the names of nations have become mere geographical expressions, the world-wide use of the English tongue will remain the noblest and the most enduring monument to the energy and genius of our race.

DISCUSSION.

Miss A. Deane Butcher, in opening the discussion, said the Hon. J. Cody, Minister of Education in Canada, had given her his card in order that she might speak in his name. Mr. Cody had written: "Why did not England trade with the French Canadians?" French Canadians could not speak or understand a single word of the English language. In order to overcome that difficulty, why did not English people send out their trade circulars properly printed? At the present time English circulars that were sent out were printed with thirteen vowel sounds and in 104 different illogical and silly ways. The Canadian Minister of Education had therefore adopted what was called the Orthotype notation, which was merely a proper print which everybody could

understand and which took only five minutes to learn. There were forty different nationalities in Toronto, and the Orthotype notation was used for the teaching of the Chinese in that city, for the purpose of carrying out the experiment in a small way. At a recent meeting of the Society, Professor Armstrong suggested that a very drastic remedy should be applied to English headmasters, namely that they should be crucified. As a matter of fact the headmaster was not the culprit; he was simply the victim of a very bad system of education under which three years were spent in the elementary education stage in teaching printers' errors. After being taught, the children could not understand their own language; they could not pronounce a single word, and they could not explain to a foreigner the meaning of English print. The real criminal was not the headmaster but the printer. The printer had made no progress in a hundred years, and printed exactly as he did a hundred years ago. In a progressive world every book that was printed ought to be better printed than its predecessor. She had spent eleven years on the Continent studying the question from the commercial point of view, and she was able to echo Mr. Gladstone's statement that the English printer made this nation a laughing-stock on the Continent. Providence had arranged that English ideals should go all over the world in English speech and in English writing. The English language was not an art, but the English print was; it was a graphic art of expression; but nevertheless there was a whole army of printers who had forced upon the nation an iniquitous and pernicious print for over a hundred years. The printer said it was not his fault, but that it was due to the type-founder, who made him buy founts of type which he was obliged to use. It was a disgrace that the nation should be absolutely under the thumb of the type-founders, some of whom could not even read. If an absolutely false notation was used, illogical children must as a consequence be brought up, and it was absolutely impossible that English trade should go all over the world. Every business man knew perfectly well that what he sold abroad depended on the character of the circular he sent out. During the eleven years that she was in France, Italy and Germany studying the question she did not find a single man, from the Chamberlain of the Pope down to a Paris coachman, who did not want to learn the English language, because they thought they were going to make money thereby. They all wanted to learn the English language, and why should the English printer prevent them? Dr. Cody also said that the Germans from Chicago held the whole of the trade with the French Canadians simply because English printers would not send a sensible circular to them. She suggested that every patent medicine, every piece of soap, every piece of machinery, should be wrapped up in intelligible English print, and that the trader should thereby circulate the English language.

Mr. J. Munford said that as a wicked headmaster he desired to make a few remarks on the interesting paper which had been read. It was probably of greater importance than any other speech delivered in London that day, or which had been delivered in London for many a long day. The spread of the English language meant the development of English manufactures and industries, and the safety and security of the Empire. For the past fifty years he had advocated the use of phonetic spelling, and he was at the present time a member of the Committee of the Simplified Spelling Society. The great difficulty in teaching the English language was its diabolical spelling. The late Archbishop of Canterbury, Dr. Temple, who had been headmaster of Rugby, one of the greatest authorities on education who had ever lived, told him that if he had his way he would spell judge "juj," and that if phonetic spelling was adopted in this country as, for instance, in Italy, one whole year would be saved in the educational life of every child. If a school-child who was preparing his work for the following day was asked what he was doing he always gave the same answer: "Spelling and Tables." Personally, if he had his way he would throw the spelling-book into the fire and put the table-book on the top of it.

Mr. Montagu C. Butler said he was certain that most of those present felt inclined to say "Hear, hear" to almost everything the reader of the paper had said, but personally he differed very strongly from him in the remarks he had made in regard to Esperanto. He was one of the misguided fanatics who very strongly believed in Esperanto as perhaps the greatest means of bringing the nations together. He was convinced that in perhaps five hundred or a thousand years—possibly very much earlier—there would be a universal language, and although it was difficult to prophesy he believed that it would be either English or Esperanto. At any rate, he asked that Esperanto should not be dismissed as a mere fad without every consideration being given to what could be said in favour of it. He urged that the study of Esperanto should be looked into, not in opposition to the English language, but as an aid to the English language and to world friendship in many ways.

Captain Harold Goad said that recently, after his return to Constantinople, he had looked a little more deeply than he had hitherto done into the subject under discussion, and found that the prospects for the foundation of an institute either in Constantinople or in Salonica were far greater than he had previously imagined. Everybody assured him that in two years such an institute would be practically self-supporting; all that was required was that a capable organiser should be sent out and guaranteed for two or three years a certain amount of money which would enable him to start and go forward. In Constantinople there

was a need for a central school or an institute, not only for the education of young Turks or young Armenians, who would subsequently go and teach in the Armenian and Greek schools which had been established throughout the Turkish Empire through the charity of the Armenians and Greeks, but also for British subjects in Turkey. The Government had appointed a strong committee to look into the whole question and advise what should be done, and he thought the time had arrived when those concerned should push for all they were worth in order to obtain something that would be permanent and definite. If some conception could be formed on the part of those interested as to what was really the best method of procedure in order to spread the education in English that was so fervently desired, he thought it would be obtained much more easily at the present time than had been the case in the past or would be the case in the future. The Government had now come up to the sticking-point, and every endeavour must be made not to allow them to turn back. The necessity of something being done had been urged by many of the Balkan peoples. Quite recently the Serbian Government had asked for not less than three hundred English elementary school teachers to be sent to Serbia to teach in the schools. He believed that offer was declined, for the reason that to send out such a large number of teachers without some sort of direction would probably defeat its own object, because many of the teachers might go out without much knowledge of the condition of affairs they were likely to encounter, and might as a result return after a very short time to this country, thus bringing discredit upon themselves and throwing a wet blanket over the enthusiasm displayed by the Serbian Government in the project. It was thought it would be better to adopt a system similar to that initiated in Florence, namely, to establish a school at which teachers of the country could learn the language sufficiently well to take diplomas for teaching in the public schools, and that he hoped would be done. He was not at one with the author in his suggestion that travelling teachers would accomplish the object in view more economically and with greater effect than an institute of an expensive nature. On the other hand, if the Government decided to take action in the matter and to spend a certain amount of money, it might be possible to carry through a more ambitious project, *i.e.* they might be induced to start in the principal capitals of Europe an English school for teachers who would go out to teach in the elementary or secondary schools of the country, and in that way the effect would be spread more rapidly than would otherwise be the case. In Constantinople alone the French had six hundred schools in which the teaching of French was compulsory; these were controlled by the French Government through the "Alliance Française," the schools being paid so much annually on condition that French was a compulsory subject. This country could not hope to go as far as that, but it could at least make it possible for the Serbian, the Bulgarian, and the Greek Governments to find material at hand for teaching English in all their schools, and in a very short while the scheme would probably become self-supporting. That, he thought, would be the best solution of the whole matter, because such a possibility would probably induce the Foreign Office to take a bold and strong line.

THE CHAIRMAN (Sir Edward W. Brabrook, C.B.), in moving a hearty vote of thanks to the author for his paper, said he did not know whether it could be truthfully said that the prevailing characteristic of the English was modesty, shyness and want of self-assertion, but it seemed to be something of that kind after hearing what the author had said as to the manner in which other countries were preparing to promote the knowledge of their own languages and the little which had been done by this country. He was very glad to think that, of that little, a very large proportion had been done by the personal exertions of the author. Mr. Hayes was still actively engaged in the promotion of that work, and he was quite certain the paper he had read would have a great weight in rousing public interest in the movement of which he was the prominent head.

The resolution of thanks was then put and carried unanimously.

MR. ALFRED E. HAYES, after thanking those present for the hearty manner in which the vote of thanks had been passed, said he naturally felt very strongly on a subject to which he had given the greater part of his so-called leisure for over sixteen years, and he was very glad indeed to hear from Captain Goad that there was now some prospect of the British Government lending a helping hand. He was delighted to hear what Captain Goad had said in regard to the prospect of the Institute in the Balkan States becoming self-supporting, although, personally, he was not in favour of a great deal of money being spent by English people in teaching their language abroad, whatever the French might do. He was convinced that there were means and methods by which it would be possible to develop the active demands in foreign countries for the teaching of English in a native and indigenous manner and at once to build up self-supporting institutions, perhaps of a simpler, but of a very effective nature, which would naturally grow year by year.

The meeting then terminated.

WILD SILK INDUSTRY IN SOUTH-EASTERN MANCHURIA.

The most interesting and important industries in the city of Antung, and perhaps throughout the whole of the district, are those connected with the various processes employed in the production of the so-called "wild silk." This silk, which in

its reeled form is known commercially as "tussah," and when woven, as "pongee," has steadily grown in popularity both in the Far East and in America and Europe, and, thanks to successful experiments in dyeing, is destined in the future to be in even greater demand. Its tensile strength and beautiful natural golden brown colour are chiefly responsible for its popularity.

The silkworm is known to the Chinese as the shan tsan or mountain silkworm, and scientifically has been variously classified by different authorities. Among the classifications given are Antherea pernyi, Bombyx pernyi, and Bombyx fertoni. Both in size and general appearance it is quite different from the silkworm which produces the better known white silk. On maturity it varies in length from three to five inches, and is of a soft green colour, with tufts of reddish-brown hairs at different parts of its body.

While the white silkworm must have the leaves of cultivated mulberry trees for its food, its less particular and more hardy northern cousin subsists on the leaves of several species of dwarf mountain oak which are native to eastern Manchuria, and grow uncultivated in great abundance on the sides of the otherwise rather unproductive hills that traverse this entire district. These trees serve the purposes of sericulture best when at a height of from five to six feet, and are accordingly kept from growing too tall by prunings made at intervals of several years. Where the natural groves are insufficient, recourse is had to artificial planting from seed. This, however, is a slow process, since from four to seven years' growth is required to produce a tree useful for feeding, and the trees are not at their best until they are from twelve to sixteen years old.

The cocoons used for propagation purposes are naturally selected from crops which have shown special quality. When it is about time for the butterflies to emerge the cocoons are strung on cords and suspended in a quiet room. The opening through which egress is made is created by means of a secretion that dissolves the fibres at one end of the cocoon. After their emergence the males and females are allowed to remain together for but one day, after which the former are released to fly where they will. The females are then taken to the place where it is desired that they should lay their eggs. In the spring this is in a basket filled with straw or twigs, and in the autumn, when the crop of leaves is ready for eating, direct to the oak trees. Each female lays an average of 150 eggs and is then released to spend the short remainder of her life where she sees fit. A period of from one to two weeks is required for the eggs to hatch. When there are indications that the spring crop of leaves will be late, hatching is retarded by means of exposing the eggs to the cold.

From the time of hatching to the commencement of the spinning of the cocoons a period of from forty to forty-five days elapses, during which the larva passes through five feeding and four sleeping phases, each transition being marked by the changing of the skin and an increase in size. The average time required for the spinning of the cocoon is from three to eight days.

According to a report by the United States Consul at Antung, the great fluctuations in the annual crops are occasioned principally by the many dangers to which the silkworm is exposed during the larva stage. The depredations of birds, stinging insects, and even of the ant, work great havoc at this time and require the most constant attendance if they are to be prevented. Fortunately, this is work that women and children can accomplish, thus releasing the men for the more arduous farm labour.

Two crops of cocoons, one in the spring and another in the autumn, are produced annually. The spring crop, which is put on the market early in July, is the smaller of the two and is used principally to produce eggs for the autumn crop, which is usually marketed after the middle of October. Cocoons are packed by the farmer in large woven willow baskets containing about 30,000. A basket freshly packed weighs approximately 400 lb. The weight, however, is reduced to about 270 lb. by the following spring owing to the shrivelling up of the chrysalides during the dry winter season.

The cocoons are transported to Antung, where they are stored in large walled or fenced enclosures and in warehouses until sold. Cocoons and spun silk are sold through large firms in Antung, who, through their familiarity with both the yearly production and with the market demands, are enabled to act as brokers, and to collect a commission for their services from both the seller and the producer. The purchasers, apart from the local filature owners, are chiefly representatives of filatures in Chefoo, Shanghai and Japan, who go to Antung as soon as the season opens to secure their stocks.

While the production of wild cocoons is a common industry throughout the entire district, the main centres are situated in the south, with Kaiping (in Mukden district) in the west and Antung in the east as the most important. In both of these cities many filatures (factories in which the thread is reeled off from the cocoons) are situated.

Cocoons which are intended for reeling during the winter months may be stored in baskets with sufficient covering to keep out rain and snow. Those, however, which it is intended to carry over to the following summer before using must have the chrysalides killed before spring, as otherwise when the weather becomes sufficiently warm the butterflies will develop and pierce the cocoons, thus partially spoiling them. The usual method of killing the chrysalides is by storing the cocoons in large warehouses capable of being heated, and in the midst of the extreme cold season raising the temperature to that of a spring day for a period of several days, after which it is lowered to that obtaining out of doors. When this process has been repeated several times all the chrysalides may

safely be assumed to be dead and the cocoons carried over to summer with no danger of being pierced.

Cocoons are prepared for reeling by a process of steaming which serves to dissolve the secretion with which the component fibres have been fastened together. This process also kills the chrysalides in the case of the cocoons which have not been treated by the process just described. Steaming is done in large iron cauldrons sunk into brick stoves, which are usually placed in a room immediately adjoining that in which the reeling is to take place. The cauldron is first filled with a solution made by dissolving in water approximately six to eight ounces of soda for each thousand cocoons to be steamed, and after this mixture has been heated to the boiling point the cocoons are thrown in and rapidly stirred for several minutes. They are then dipped out and put into a round container not unlike a deep sieve in appearance, but with parallel strips of bamboo for a bottom, which is placed immediately over the cauldron so that the bamboo slats are only an inch or more above the surface of the boiling solution, and in this position are steamed for several hours.

When the process of steaming has been completed the inextricable mass of tangled fibres which form the outer covering of the cocoons, and which is known as ta-wan-shu, or "big waste," is removed; the innermost fibres which actually enwrap the chrysalides are hopelessly tangled, and are known as the erh-wan-shu, or "second waste." From its nature waste cannot be reeled, as is the thread, but must be chopped up, combed, carded and spun. Hitherto the waste has always been shipped to Europe for manufacture.

After the outer waste has been removed the cocoons are taken into the reeling room and distributed to the reel operators, who are usually arranged on high platforms running the length of a long narrow room, one operator to a reel. Each operator then gathers the ends of the fibres of from six to eight cocoons, twists them into a thread which he fastens to his reel, and by means of a treadle starts the reel revolving. As the thread passes through several rings before reaching the reel it is twisted, and is wound on to the reel in the form of the finished thread. The reels are of two sizes, one with a diameter of 1½ ft. and the other 2½ ft., and in Antung are all operated by foot power.

The average capacity of an operator is from 700 to 900 cocoons a day, while the experts attain occasionally to 1200. The skeins, which are usually some 4 ft. in circumference, are folded once and twisted spirally. The thread, when it has been manufactured into skeins in this manner, is known as "tussah."

The silk-producing qualities of the spring and autumn cocoons are different. One thousand spring cocoons will furnish from 5½ oz. to 8 oz. of tussah, whereas the autumn cocoons yield from 8 oz. to 12 oz. The silk produced from the spring cocoons is of a softer and more pleasing texture than that from the later ones.

Tussah is classified by the Chinese trade into five grades, known as "extra," "No. 1," "No. 2." "No. 3," and "No. 4," according to quality. It is also divided into two general classes, "not filature" and "filature." The term "not filature" is applied to that reeled on a small scale in many different localities, and which as a result lacks uniformity, while "filature" is used to describe the product of the larger factories, which maintain standards of approximate uniformity.

Waste is commercially divided into two classes—No. 1 and No. 2—which correspond generally to the "big waste" and "second waste" already described. It is usually put up into bales of from two to three piculs (266⅔ lb. to 400 lb.)

The silk filature industry in Antung city is only twelve years old. In the year 1907 two small filatures were started, one under the auspices of the local Chinese officials, and employing 120 hands, and the other a small Japanese enterprise employing Chinese labour. The number of reels in one of the larger filatures ranges from 300 to 1200, and in the smaller ones from 25 to 100. In addition to these regular filatures a considerable amount of reeling is also done in private houses and as a sideline in other places of business.

Hitherto Chefoo has been the centre of both the reeling and weaving of wild silk, but in recent years the owners of filatures have steadily been moving their establishments to Antung. The change is a natural one, as it is cheaper to reel off the silk at the source of supply, and thus remove from the cost of production the items of transportation of cocoons and of duties levied by the Chinese customs. To this has now been added the further plan of moving the pongee weaving industry from Chefoo to Antung. In order to ensure success and to eliminate wasteful competition it is proposed that a single large weaving mill be established, the capital of which is to be contributed by the owners of the filatures.

A Japanese company, known as the Anto Yoko Manshu Kemmo Boseki Koba, has constructed a large factory in which it is proposed to spin silk "waste" into thread, and with this to weave various fabrics for the American and Japanese markets. The machines are to be of a variety especially suited for the purpose and are to be worked by electricity.

When the proposed large pongee weaving mill and the factory for the manufacture of the "waste" are put into operation, Antung will not only be the centre of cocoon production and "tussah" reeling, but of the final process of manufacture as well. As, comparatively speaking, only a small portion of the land in the Antung district suitable for growing scrub-oak is now so used, and since with the ever-increasing Chinese population there will be no possibility of a shortage of the necessary labour, the dimensions to which the industry can attain are limited solely by the world demand for tussah and pongee.

HORSE-BREEDING IN BRAZIL.

The following is a translation, by the United States Vice-Consul at Rio de Janeiro, of an interesting account of horse-breeding in Brazil prepared by the Brazilian Foreign Office :—

In Brazil vast areas are available for horse-breeding. The horses of this country are derived from different races, which, by crossing with pure-bred English, Norman, and French stock, have developed a distinct national type. Small, light, and intelligent, the Brazilian horse is useful for military purposes and is excellent for the saddle, answering readily to the demands of the rider, and enduring long journeys without food.

Federal and State Governments alike have taken the initiative in the selection and crossing with pure British breeds, and haras or official studs have been started in several States.

The Brazilian stud counted 6,065,730 head in 1916, distributed as follows :—

Alagoas	96,590	Parana	217,090
Amazonas	8,740	Pernambuco	211,980
Bahia	809,940	Piauhy	164,690
Ceará	218,300	Rio do Janeiro	142,890
Federal District	5,600	Rio Grande do Norte	95,680
Espirito Santo	78,590	Rio Grande do Sul	1,056,110
Goyaz	265,830	Santa Catherina	140,070
Maranhão	148,590	São Paulo	497,970
Matto Grosso	140,490	Sergipe	96,040
Minas Geraes	1,505,600	Acre Territory	530
Pará	57,650		
Parahyba	106,760		

The war has played havoc with horses in many countries, and, according to the following estimates, Brazil should be in a position now to make good part of these losses. World's figures are as follows: Russia in Europe, 23,860,178; United States, 21,123,000; Argentina, 9,427,000; Russia in Asia, 6,577,693; Brazil, 6,065,730; Austria-Hungary, 4,370,884; Germany, 3,341,627; Canada, 2,990,635; Australia, 2,521,983; France, 2,317,205; India, 1,818,873; United Kingdom, 1,699,640; Japan, 1,533,829; Italy, 955,878; Union of South Africa, 714,414; Sweden, 599,136; Cuba, 560,580; Uruguay, 556,307; Chile, 553,869; Spain, 525,853; Denmark, 515,415; Bulgaria, 477,233; New Zealand, 404,284; Holland, 384,445; Belgium, 317,080; Algeria, 221,178; Switzerland, 186,513; Serbia, 152,136; Tunis, 88,000; Portugal, 87,765; Costa Rica, 52,095; Egypt, 47,911.

So far, exports of horses from Brazil are practically nil. In 1917 only one horse, valued at 900 milreis, was exported, but 353 were imported for breeding purposes in 1916, and 382 in 1917.

GENERAL NOTES.

Miss Eleanor Rowe.—Miss Eleanor Rowe, who died on January 3rd, was for some twenty years manager of the School of Art Wood-carving, South Kensington. The school was founded by the Royal Society of Arts in 1878. Its first quarters were in Somerset Street, Oxford Street, and after various changes it moved in 1908 to its own premises in Thurloe Place. Miss Rowe was a skilful craftswoman and a good organiser, and she also wrote several excellent text-books, including "Hints on Wood-carving," which ran through many editions; "Practical Wood-carving," which has now been republished in two volumes; and a series of reproductions, "Studies from the Museums" and "French Carvings from the Museums," with a preface giving a history of the periods covered by the French Renaissance. It was Miss Rowe's enterprise that opened the Schools of Architecture to women. As head of a large and growing craft school, she felt it necessary to obtain a thorough knowledge of fine art architecture, and finding that the National Art Training School at South Kensington (now the Royal College of Art) would not admit women to its architectural courses, she joined the course of Fine Art Architecture under the late Professor Roger Smith, at University College. He soon became aware of the excellence of his pupil, but he found that the rules of the College barred women from the architectural courses. He could see no reason for such a rule, and he therefore put the ease to her fellow-students, who were all men, and took their vote on the subject. The vote was unanimously in favour of granting her and all future women students the same privileges they themselves enjoyed, and opening all the examinations and awards to them. This led to an official decree endorsing their vote. Miss Rowe passed the final examination with high honours, and was followed the next year by two other women students from the School of Wood-carving, who also took the highest awards after the gold medal.

Oil-driven Ships.—Mr. J. H. Williams, at a meeting of the Institute of Marine Engineers at the Minories on January 27th, said that the Americans were a long way ahead of us in the use of oil fuel for ships. There was hardly an American ship coming over to-day that was not burning oil. As a rule, for shipping oil was a cheaper fuel than coal, and in many ports it was half the price of coal. In South America oil was displacing coal very rapidly.—"*Times*" *Trade Supplement.*

Cotton Shortage.—Presiding at the annual general meeting of the shareholders of the London, County, Westminster and Parr's Bank, Mr. Walter Leaf referred to the sudden and very serious increase in the cost of cotton, which was likely to hamper, in the very near future, the growth of our greatest textile industry. This increase was quite independent of any question of exchange; it was due to an alarming shortage of the raw material. The American crop had been materially curtailed by the ravages of an insect pest, which was, unfortunately, spreading till it threatened the complete destruction of the Sea

Island cotton. At the same time the United States were competing with us for the limited crop of Egyptian cotton, which was of the utmost importance to Lancashire, with the result that the price had been forced up from about 29*d.* at the beginning of October to no less than over 74*d.* to-day. The prospect was undoubtedly serious, and it was to be hoped that speedy effect would be given to the efforts which were being made to extend the growth of cotton within the Empire.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday afternoons, at 4.30 p.m. :—

February 18. — Sidney Preston, C.I.E., "English Canals and Inland Waterways." Neville Chamberlain, M.P., will preside.

February 25. — James Currie, C.M.G., Ministry of Labour (Training Department), late Principal, Gordon Memorial College, Khartoum, "Industrial Training."

March 3.—William James Garnett, First Secretary, H.B.M. Diplomatic Service, "Mongolia from the Commercial Point of View."

March 10.—H. M. Thornton, "Gas in relation to Industry and Housing." Sir Robert A. Hadfield, Bt., D.Sc., F.R.S., will preside.

March 17. — William Worby Beaumont, M.Inst.C.E., "Street Passenger Transport of London."

March 24.—Air-Commodore Edward Maitland, C.M.G., D.S.O., A.F.C., "The Commercial Future of Airships."

April 14.—Joseph Thorp, "The Fundamental Basis of Good Printing."

Indian Section.

Friday afternoon, at 4.30 p.m. :—

March 19.—Sir William S. Meyer, G.C.I.E., K.C.S.I., Financial Member of Council of the Governor-General of India, 1913-18, "The Indian Currency System and its Developments."

Thursday afternoons, at 4.30 p.m. :—

April 15.—Brigadier-General Lord Montagu of Beaulieu, C.S.I., "Roads and Transport in India."

May 20.—Sir George Cunningham Buchanan, K.C.I.E., M.Inst.C.E., "The Ports of India: their Administration and Development."

Date to be hereafter announced :—

Sir Valentine Chirol, "The Enduring Power of Hinduism." (Sir George Birdwood Memorial Lecture.)

Colonial Section.

Tuesday afternoons, at 4.30 p.m. :—

March 2.—G. F. Scott Elliot, M.A., B.Sc., F.R.G.S., "Trade Routes for the Empire in Africa." Colonel Sir Thomas H. Holdich, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., will preside.

May 4.—Professor William A. Bone, D.Sc., Ph.D., F.R.S., "Lignite."

Indian and Colonial Sections (Joint Meeting).

Date to be hereafter announced :—

Professor Sir John Cadman, K.C.M.G., D.Sc., F.G.S., M.Inst.C.E., "The Oil Resources of the British Empire."

Dates to be hereafter announced :—

Charles H. Sherrill, "Stained Glass."

Graily Hewitt, "Rolls of Honour."

Charles Crowther, "The Arts and Crafts of Japan" (with examples from the author's private collection).

William Cramp, D.Sc., M.I.E.E., "Pneumatic Convoying Plants, with special reference to the Transport of Grain."

L. Gaster, "Industrial Lighting in its relation to Efficiency."

Cantor Lectures.

Monday evenings, at 8 p.m. :—

Charles Frederick Cross, B.Sc., F.R.S., F.C.S., "Recent Research in Cellulose Industry." Three Lectures.

Syllabus.

Lecture I.—February 16.—*Compound Celluloses.* (*a*) Lignocelluloses: (1) Jute: Heart damage of baled jute—Bearings on problems of constitution and formation, and on industries—Special treatment of jute and jute fabrics for decorative and "useful" applications; (2) Esparto: As a special type of lignification—New researches; (3) Woods: Lignification and de-lignification—Relations of lignone to their "aromatic" by-products. (*b*) Cutocelluloses, a special chemistry of raffia—The question of natural cellulose esters, and a technical ideal.

Lecture II. — February 23. — *The Cellulose Industries.* Cotton-spinning — Investigations of factors of process and qualities of products —Raw cotton and (normal) bleached cotton—Artificial silk, controlled hydration of celluloses by chemical process and a critical re-investigation of paper-making processes—Twisted paper yarns.

Lecture III.—March 1.—*Cellulose and Derivatives.* Nitrates—Acetates—Progress of research and industry—Specific volumes of cellulose and hydrates—Data of fundamental importance, scientific and industrial—The problems of constitution.

Walter Rosenhain, B.A., D.Sc., F.R.S., Superintendent, Department of Metallurgy and Metallurgical Chemistry, National Physical Laboratory, "Aluminium and its Alloys." Three Lectures.

April 12, 19, 26.

Arthur Thomas Bolton, F.R.I.B.A., F.S.A., Curator, Soane Museum, "The Decoration and Architecture of Robert Adam and Sir John Soane, 1758-1837." Three Lectures.

May 3, 10, 17.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, FEBRUARY 16...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. C. F. Cross, "Recent Researches in the Cellulose Industry." (Lecture I.)

Victoria Institute, Central Hall, Westminster, S.W., 4.30 p.m. Rev. A. H. Finn, "The Silences of Scripture."

British Academy, King's College, Strand, W.C., 5.30 p.m. Ven. Archdeacon Charles, "The Apocalypse." (Lecture III.)

Surveyors' Institution, 12, Great George-street, S.W., 8 p.m. Captain W. H. Tapp, "Survey on the Western Front."

Geographical Society, 135, New Bond-street, W., 8.30 p.m. H.E. the Spanish Ambassador, "The Spanish Zones in Morocco."

TUESDAY, FEBRUARY 17...Petroleum Technologists, Institution of, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5.30 p.m. Dr. W. R. Ormondy, "Recent Patents on Mixed Fuels."

Statistical Society, 9, Adelphi-terrace, W.C., 5.15 p.m. Professor E. H. Starling, "Food Conditions in Germany during the War."

University of London, London Institution, Finsbury-circus, E.C., 5 p.m. Mr. A. D. Innes, "The Mogul Period of the History of India." (Lecture II.)

Royal Institution, Albemarle-street, W., 3 p.m. Professor E. Wilson, "Magnetic Susceptibility." (Lecture I.)

Roman Studies, Society for the Promotion of, at the Society of Antiquaries, Burlington House, W., 4.30 p.m. Mr. N. H. Baynes, "The History of Rome in Teaching and Research."

Photographic Society, 35, Russell-square, W.C., 7 p.m. Mr. N. E. Luboshez, "Fancy Lighting in Portraiture."

Anthropological Institute, 50, Great Russell-street, W.C., 8.15 p.m. Mr. J. R. Moir, "On the Occurrence of Flint Implements of Man in the Glacial Chalky Boulder Clay of Suffolk."

WEDNESDAY, FEBRUARY 18...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Mr. S. Preston, "English Canals and Inland Waterways."

Aeronautical Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Squadron-Leader P. Bishop, "Aircraft Design in relation to Standardisation."

Meteorological Society, 70, Victoria-street, S.W., 5 p.m. 1. Captain C. J. P. Cave, "The Status of a Meteorological Office and its Relation to the State and to the Public." 2. Mr. W. H. Dines, "Atmospheric and Terrestrial Radiation." 3. Mr. D. Brunt, "Internal Friction in the Atmosphere."

Microscopical Society, 20, Hanover-square, W., 8 p.m. 1. Mrs. A. Arber, "Studies on the Binucleate Phase in the Plant-cell." 2. Mr. R. Beer and Mrs. A. Arber, "Multinucleate Cells: an Historical Study (1879-1919)." 3. Mr. S. C. Akehurst, "Exhibition of Professor Silverman's Illuminator for Opaque Objects."

United Service Institution, Whitehall, S.W., 3 p.m. Colonel A. H. W. Haywood, "The Campaign in the Cameroons."

Industrial League and Council, Central Hall, Westminster, S.W., 7.30 p.m. Mr. W. J. Grosart, "Evolution of Modern Method in Industry."

THURSDAY, FEBRUARY 19...ROYAL SOCIETY OF ARTS, 3 p.m. Conference on House Furnishings at the Ideal Home Exhibition, Olympia, W.

Royal Society, Burlington House, W., 4.30 p.m.

Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Linnean Society, Burlington House, W, 5 p.m. 1. Messrs. J. S. Huxley and D. F. Leney, "Specimens of Sexually Mature Axolotls metamorphosed into the Amblystoma Form by feeding with thyroid gland, and of Urodele Larvæ precociously metamorphosed by treatment with Iodine Solution." 2. Major H. C. Gunton, "Entomologico-Meteorological Records of Ecological Facts in Life of British Lepidoptera."

Chemical Society, Burlington House, W., 8 p.m. 1. Messsrs. S. B. Schryver and C. C. Wood, "A new method for the estimation of methyl alcohol." 2. Messrs. C. S. Gibson and W. J. Pope, "$\beta\beta'$-dichlorethyl sulphide." 3. Messrs. W. K. Slater and H. Stephen, "Some derivatives of fisetol." 4. Mr. M. F. Barker, "Calorific value and constitution." (Part I.) 5. Mr. J. B. Firth, "Surface tension of alcohol-water mixtures."

Royal Institution, Albemarle-street, W., 3 p.m. Mr. A. H. Smith, "Illustrations of Ancient Greek and Roman Life in the British Museum." (Lecture I.)

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m.

Electrical Engineers, Institution of, at the Institution of Civil Engineers, Great George-street, S.W. (Wireless Section), 6 p.m. Major C. E. Prince, "Wireless Telephony on Aeroplanes."

Auctioneers and Estate Agents' Institute, 34, Russell-square, W.C., 7 p.m. (Junior Members.) Mr. E. Woolf, "Some Probable Problems at the Coming Quinquennial Valuation."

Mining and Metallurgy, Institution of, at the Geological Society, Burlington House, W., 5.30 p.m.

FRIDAY, FEBRUARY 20...University of London, University College, Gower-street, W.C., 5 p.m. Dr. T. Borenius, "Mediæval Art." (Lecture VI.)

Royal Institution, Albemarle-street, W., 9 p.m. Dr. E. J. Russell, "British Crop Production."

Dyers and Colourists, Society of, Huddersfield. Mr. H. H. Hodgson, "Research—its place and function in an Educational System."

Manchester. Professor F. L. Pyman, "The Properties of the Glyoxaline Ring."

Concrete Institute, 296, Vauxhall-bridge-road, S.W., 6 p.m. Mr. H. K. Dyson, "Some Points in Reinforced Concrete Design."

Mechanical Engineers, Institution of, Storey's-gate, Westminster, S.W., 6 p.m. 1. Annual General Meeting. 2. Discussion on Mr. Bergstrom's paper, "Recent Advances in the Utilisation of Water Power."

SATURDAY, FEBRUARY 21...Royal Institution, Albemarle-street, W., 3 p.m. Professor Sir J. J. Thomson, "Positive Rays." (Lecture I.)

Journal of the Royal Society of Arts.

No. 3,509. VOL. LXVIII.

FRIDAY, FEBRUARY 20, 1920.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

MONDAY, FEBRUARY 23rd, at 8 p.m. (Cantor Lecture.) Mr. CHARLES FREDERICK CROSS, B.Sc., F.R.S., "Recent Research in Cellulose Industry." (Lecture II.)

WEDNESDAY, FEBRUARY 25th, at 4.30 p.m. (Ordinary Meeting.) JAMES CURRIE, C.M.G., Ministry of Labour (Training Department), late Principal, Gordon Memorial College, Khartoum, "Industrial Training." THE RIGHT HON. SIR ROBERT S. HORNE, K.B.E., K.C., M.P., Minister of Labour, will preside.

Further particulars of the Society's meetings will be found at the end of this number.

CANTOR LECTURE.

On Monday evening, February 16th, DR. M. O. FORSTER, F.R.S., in the chair, Mr. CHARLES FREDERICK CROSS, B.Sc., F.R.S., delivered the first lecture of his course on "Recent Research in Cellulose Industry."

The lectures will be published in the *Journal* during the summer recess.

TENTH ORDINARY MEETING.

WEDNESDAY, FEBRUARY 18th, 1920; Mr. NEVILLE CHAMBERLAIN, M.P., in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Brunyate, Sir James Bennett, K.C.S.I., C.I.E., London.
Dongarsingh, Ramsingh, London.
Hunt, J. H., Dayton, Ohio, U.S.A.
Hutchinson, Lieut.-Colonel Thomas Massie, D.S.O., O.B.E., British Troops in France.
Layton, Gordon Shakespeare, Bury St. Edmunds.
Mackley, Edward N., Gateshead-on-Tyne.
Needler, F., Hull.
Nelson, Amos, J.P., Thornton-in-Craven, near Skipton.
Parsons, Lieut. Percival A., A.I.F., London.
Peto, William, M.I.E.E., London.

The following candidates were balloted for and duly elected Fellows of the Society:—

Brougham, William Henry Charles, Wallington, Surrey.
Darby-Legge, Captain A. W., R.A.S.C., London.
Doyle, Trevor Mervyn, Sydney, New South Wales.
Early, James Vanner, Witney, Oxon.
Garforth, Sir William E., LL.D., M.Inst.C.E., Pontefract.
Gibson, Alfred Herbert, F.S.S., Harrogate.
Guthrie, Thomas Maule, J.P., Brechin.
Holmes, William, London.
Hoxie, William D., New York City, U.S.A.
Hughman, Ernest Montague, Calcutta, India.
Lovekin, Luther D., Philadelphia, Pa., U.S.A.
Macara, Sir Charles Wright, Bt., Manchester.
Nasmith, Frank, Manchester.
Nicoll, Allardyce, M.A., Horton-cum-Studley, Oxon.
Powell, A. Cecil, Weston-super-Mare.
Shafik Pasha, H. E. Mohamed, Minister of Agriculture, Cairo, Egypt.
Stanners, Robert Whitfield, B.Sc., M.A., Cambridge.
Unwin, Mrs. Jane Cobden, London.
West, Edgar Louis, B.A., Rocester, Staffordshire.
Willson, P. G., London.
Wright, Commander Nathaniel H., U.S. Navy, Washington, D.C., U.S.A.

A paper on "English Canals and Inland Waterways" was read by Mr. SIDNEY PRESTON, M.Inst.C.E., C.I.E., Vice-Chairman of the Canal Control Committee (Board of Trade).

The paper and discussion will be published in a subsequent number of the *Journal*.

CONFERENCE ON HOUSE FURNISHINGS.

THURSDAY, FEBRUARY 19th, 1920; The Right Hon. SIR AUCKLAND GEDDES, K.C.B., M.P., President of the Board of Trade, in the chair.

A conference on House Furnishings was held in connection with the Ideal Home Exhibition at Olympia.

A full report of the Conference will be published in a subsequent number of the *Journal*.

PROCEEDINGS OF THE SOCIETY.

COLONIAL SECTION.

A meeting of the Colonial Section was held on Tuesday, February 3rd, 1920; LIEUT.-COLONEL SIR DAVID PRAIN, C.M.G., C.I.E., LL.D., F.R.S., Director of the Royal Botanic Gardens, Kew, in the chair.

THE CHAIRMAN said that the author of the paper, Sir Francis Watts, was unfortunately not present to read his paper. When in England last he was induced to prepare it at the invitation of the Society, but it was not possible for him to complete it before he returned to Barbados.

The paper read was—

TROPICAL DEPARTMENTS OF AGRICULTURE, WITH SPECIAL REFERENCE TO THE WEST INDIES.

By SIR FRANCIS WATTS, K.C.M.G., D.Sc.,
Imperial Commissioner of Agriculture for the West Indies.

Tropical departments of agriculture have arisen by an interesting process of evolution, in which the West Indies have been concerned to no small extent.

The geographical discoveries of the fifteenth and sixteenth centuries led to great interest being taken in the various plants and products found in newly-discovered countries, while the desire to colonise these countries was accompanied by the natural tendency to cultivate many of the plants then found for the first time, or then first made familiar as the source of commodities which had for some time reached European countries through devious channels, such as the caravan routes of the East or trade routes through the Red Sea.

In addition to cultivating the plants found in different countries, much effort was expended on attempts to introduce desirable plants into some of the new-found countries, and in this way there arose such epoch-making introductions as that of the sugar-cane from the Eastern to the Western world, tobacco, maize, potatoes, and other products from the West to the East, together with such carefully-planned efforts as were involved in the introduction of the bread-fruit from the Pacific to the West Indies, and the mango from the East also to these islands. Mere enumeration of the work done in this way would occupy the whole time of an evening's discourse.

When making introductions of new plants into new countries it soon became obvious that success could only be attained if proper provision were made for their care, at least until such time as they were propagated in such numbers as to become well established and well diffused locally. In this way there arose botanic gardens in tropical countries, whose first care was to receive such plant introductions as had been already decided upon, but which in turn soon reacted on the outlook, for those in charge of these gardens occupied themselves with the constant inquiry as to what plants could be collected and introduced into their gardens, largely with a view to ascertaining what new plants were capable of being grown in the new surroundings, and also to ascertain whether some, or many, of these would be capable of being grown commercially for profit.

At the same time, posterity owes much to the mission gardens which the early missionaries established around their stations; these served both as active centres for the introduction, acclimatisation and distribution of new plants, and also as centres whence the knowledge of the best manner of treating these introductions was disseminated amongst those into whose hands the new plants fell.

Considerable activity was displayed in these matters in the West Indies. A botanic garden was established in St. Vincent as early as 1764 and maintained until about 1830, when a number of such plants as could be moved were transferred to the botanic gardens at Trinidad. It is interesting to note that in 1772 the Royal Society of Arts awarded a gold medal to Dr. Young, who was then in charge, in recognition of the flourishing state of the garden. This garden played an important part in connection with plant introduction into the West Indies, for Captain Bligh placed here some 300 bread-fruit plants which he had brought from Tahiti: nutmeg, cinnamon and clove trees were also introduced into this garden; and to this place, also, Lord Rodney sent some of the mango and cinnamon plants which he took from a French man-of-war in 1792.

A botanic garden was also established at Bath, in Jamaica, in 1774. Various plants were brought there from Tahiti by Captain Bligh, amongst which were four varieties of sugar-cane, as well as the bread-fruit and other plants. After many changes and vicissitudes in the history of these early gardens, botanic gardens, conducted on similar lines to those with which we are now familiar, were established in the West Indies, in Jamaica and Trinidad.

The closing years of the nineteenth century

were critical ones as regards the agriculture and commerce of the British West Indies; up to that time most of the islands had been dependent upon sugar as the mainstay of their agriculture and commerce; sugar was the dominant factor in most of them; it was so in the larger colonies, such as British Guiana, Trinidad and Jamaica, as well as in Barbados, Antigua and St. Kitts; while even those islands like Grenada, St. Vincent, St. Lucia, Montserrat and Nevis, where sugar cultivation is now relatively unimportant, then depended mainly upon that industry. The period about 1883 was critical for the West Indian sugar industry, as the price of sugar fell to a point at which its production was no longer remunerative. In some of the islands where the disadvantages were most marked, the sugar industry so declined that in a few years but little sugar was being produced in such islands as Grenada, St. Vincent, Montserrat and Nevis, in most of which other industries had been substituted, as cacao in Grenada, arrowroot in St. Vincent, and limes in Montserrat and Dominica. The sugar industry was, however, maintained in a struggling condition in the more favourably situated islands of Barbados and St. Kitts, while it appeared to be moribund in Antigua.

It is not necessary to enter at length on the causes of the decline of the British West Indian sugar industry; suffice it to say that the main reason was the competition of the beet-sugar industry of the continent of Europe, aided by the very unfair system of state bounties there in vogue, whereby the sugar producers of Germany and Austria, and, to a less extent, of France, received sums ranging from £1 or £2 per ton up to, at one time, as high as over £5 per ton, for the mere act of dumping sugar into Great Britain, and this at a time when the market price of West Indian raw muscovado sugar, the type then principally made, ranged from about £7 10s. to £9 per ton. Under the fiscal system then in vogue in the United Kingdom there was no measure of protection against this condition of affairs, and the sugar industry of the West Indies would have been extinguished but for the fact that the tariff conditions in the United States permitted the importation of British West Indian sugar at moderate rates of duty, while imposing upon sugars receiving foreign bounties additional rates of duty equivalent to the bounties.

This great decline in the value of sugar led to serious consideration of the economic prospects of the West Indian colonies; this took the form of an inquiry into the possibility of so improving the method of growing the canes and manufacturing the sugar as to enable the West Indian sugar industry to compete with the beet sugar produced in Europe. Adverse fiscal conditions, however, retarded the progress in this direction for many years, and led to investigations which will be referred to later.

In addition to attention being directed to the condition of the sugar industry, much thought was given to the possibility of introducing other industries which might tend to support some, at least, of the colonies, even were they not able entirely to take the place of sugar.

In 1885, Sir Joseph Hooker, commenting on the Report of the Royal (West Indian Finance) Commission, appointed in 1883, expressed the opinion that there could be no doubt that the future prosperity of the West Indies would be largely affected by the extension to other islands, unprovided with any kind of botanical establishment, of the operations so successfully pursued in Jamaica ("Kew Bulletin," 1887, Pt. 6, p. 6). This may be taken as the starting-point in a line of policy which has considerably affected the West Indies.

In 1884 Mr. (now Sir) Daniel Morris had submitted to the Colonial Secretary of Jamaica proposals for the formation in each of the smaller British West Indian colonies of small botanical establishments, which should be placed under the direction of some local officer, the provision of skilled scientific officers hardly being contemplated, and that they should serve as centres from which there could be distributed such plants as might be successfully introduced and have consideration as the basis of new industries.

The idea underlying the proposals was that the Botanical Department at Jamaica should serve as a central institution; that it should supply to the subsidiary stations such seeds and plants as were available which it was thought it might be desirable to introduce. It was contemplated that the central establishment would only communicate with the recognised officer in each colony thus associated, who would forward requisitions and transact all business as between the local and the central establishment. It was suggested that "the control of each station would be entirely in the hands of the local government; the connection with the central establishment would be confined to dealing with applications for seed, plants, or other purposes of a purely consultative character."

At the same time it was suggested by the then Assistant Director of Kew, Mr. (now Sir) W. T. Thiselton Dyer, that, in addition to distributing plants the central institution should organise a regular system of botanical bulletins containing practical hints as to the treatment of economic plants, and the conditions under which they might best be utilised in developing remunerative industries.

With a view to giving effect to these and cognate suggestions general proposals were addressed in February, 1885, to the Governors of the several West Indian colonies, including the Bahamas and British Honduras, strongly recommending the adoption of the scheme. In consequence of the transfer of Mr. Morris from the post of Director of the Botanical Department of Jamaica to that of Assistant Director of Kew, together with various other changes and obstacles to progress, some delay was experienced in putting the whole scheme into operation. A botanic garden was, however, established in Grenada in 1886, and about the same time a small appropriation was made by the Legislature of Barbados for the purpose of forming a botanic station in connection with the boys' reformatory at Dodds, where experiments with sugar-canes had already been started on a fairly extensive scale under the direction of Professor Harrison, with whom was associated Mr. J. R. Bovell. This was the first experiment station as such in the West Indies, and from it have originated many of the varieties of sugar-cane now most widely under cultivation. In the same year the botanic garden at St. Lucia was established, and in 1890 that of St. Vincent was revived.

In order to stimulate and aid the work thus initiated, Mr. Morris, the Assistant Director of Kew, was, at the request of the Secretary of State for the Colonies, entrusted with a mission to visit the several West Indian islands. An interesting account of this mission is recorded in the "Kew Bulletin" for 1891, pp. 103-168.

As the outcome of these efforts botanic stations, or gardens, were established in Antigua (1890), St. Kitts (1891), Dominica (1890), and Montserrat (1890), while a chemical laboratory, largely devoted to the consideration of agricultural problems, was established in Antigua in 1889.

This period marks a definite advance towards the development of scientific agriculture in the West Indies. The botanical establishments thus created were closely associated with Kew, which was largely responsible for the movement which led to their formation and for the ideas and principles on which their work was based. They were maintained by the several local governments with varying degrees of interest and financial support. These establishments marked the transition period from botanical establishments to experiment stations; they were useful in that they paved the way for later developments.

The general economic conditions of the West Indies became steadily worse in the years immediately following these efforts. The price of sugar declined steadily, and there seemed to be no prospect of its improvement. The production of sugar dominated West Indian affairs and as the prices of other commodities such as cacao, arrowroot, and lime juice also showed declining tendencies, there was great apprehension as to the future, the public finances of practically all the colonies being in a straitened condition. As a result of these conditions much difficulty was experienced in obtaining adequate appropriations for the botanical establishments.

This alarming state of affairs throughout the British West Indies led to the appointment, at the close of 1896, of the West Indian Royal Commission to inquire into the conditions and prospects of the sugar-growing West Indian Colonies. The Commission visited practically all these colonies in 1897 and reported in the same year.

The report distinctly marks a period in West Indian history, and should be freely consulted by all who desire to form a sound opinion on the state of West Indian affairs at that time.

The Commission clearly recognised that the colonies in question were dependent upon agriculture and must remain so dependent; the sugar industry they saw was dominant, though they feared it would be moribund unless drastic steps could be taken to save it. This industry seemed to be almost the only one suited to the conditions of many of the islands, but it was felt that something definite should be done to ascertain whether other agricultural industries might not be encouraged and developed to such an extent that they might become the mainstay of those colonies in which sugar cultivation gave least promise of being successfully revived. In this the colonies were confronted by lack of information and by lack of means to secure and apply such information as might be available.

As the outcome of this investigation and report definite recommendations were made for

the creation of an Imperial Department of Agriculture, to be supported entirely from Imperial funds. These proposals received the whole-hearted support of Mr. Joseph Chamberlain, then Secretary of State for the Colonies.

Time does not permit of anything but the briefest statement concerning the constitution and work of this Department, but an appreciation of the manner in which it originated, how it was supported, and what it has done, is essential to an understanding of the present position of agricultural departments in the West Indies, and possibly those of several other tropical possessions of the Empire.

The Imperial Department was inaugurated in October, 1898, Mr. (now Sir) Daniel Morris being appointed Imperial Commissioner of Agriculture for the West Indies. In planning his work Sir Daniel Morris wisely built upon existing organisations; he found a good foundation ready to hand in the botanic gardens and kindred institutions which had been evolved, as already stated, largely as the result of efforts and recommendations with which he had been intimately concerned. These institutions had, however, been lamentably stunted and starved from lack of funds and from the limited outlook of the local legislatures and other authorities upon whom they depended for support.

An appropriation amounting to some £17,500 a year was made available from the Imperial Treasury, and the Imperial Commissioner established his headquarters in Barbados; he speedily got to work in inquiring into the capabilities of the agricultural organisations in all the colonies, cognisance being taken of the botanic gardens, the chemical laboratories, and all the existing institutions likely to have a bearing on agricultural development, not forgetting the schools of various grades. The work which all these agencies had been carrying on in the past was studied and plans made for continuing what was promising and useful, and for extensions in new directions. It is important to recognise this continuity of effort, for it justifies the line of activity taken by Kew and by the several Colonial Governments in the time prior to the creation of the Imperial Department, and demonstrates the value of continuity of policy when once the policy agreed upon is soundly chosen. The absence of continuity of policy in colonial government may be held to be responsible for slow development in many directions, and in this, as in many other respects, the Imperial Department may well claim to have demonstrated much that is useful in administration.

The work of the Imperial Department in the earlier years consisted in assisting the local governments to put their agricultural institutions into better order; for this purpose grants-in-aid were made to every West Indian government. In the larger colonies, including British Guiana, Jamaica, and Trinidad, the grants were supplementary to the expenditure of the local legislatures, and they served in no inconsiderable degree to stimulate the work of the agricultural organisations and to keep their work in line with that carried on in the smaller colonies where the imperial grant-in-aid entirely supported the various activities of the local departments of agriculture which were created or consolidated, as the outcome of the fostering care of the Imperial Department. It is important to recognise that this action had the effect of definite local departments of agriculture being formed out of the poorly equipped and somewhat indeterminate institutions which existed at that time in most of the islands, particularly in the smaller ones.

The money appropriated for this purpose was, in every case, treated as a grant-in-aid to the colony receiving it; it was expended on recommendations made by the Commissioner in consultation with the local executive, and duly voted by the several legislatures concerned as part of the approved expenditure of colonies.

This condition obtained until 1909—that is to say, for ten years—during which time the cost of maintaining the local departments of agriculture in the smaller colonies was borne entirely by the Imperial Government, while material assistance was given to those in the larger colonies.

At the expiration of this time, in view of the improved condition of the colonial finances, largely as the outcome of the agricultural development fostered by the work of the Imperial Department, progressive diminution of the Imperial grants to the colonies was decided upon, and it was agreed that these grants should be diminished year by year, until they ceased in 1912–13.

All this time financial provision was made from Imperial funds for the Imperial Commissioner of Agriculture, together with his staff at headquarters, and also for the cost of the maintenance of the office and laboratories at headquarters and for travelling expenses and for the issuing of various publications. This condition is maintained up to the present time.

I may, perhaps, here add that, as the result of my experience, I feel that this is a condition essential to success, and that any attempt to depart from it will be detrimental to the interests of the work as a whole.

In this manner the following amounts have been granted to the several colonies in the years between and including 1898–9 and 1912–13, when the grants-in-aid ceased :—

	£	s.	d.
British Guiana	3,852	14	0
Trinidad	3,563	9	4
Jamaica	2,265	1	0
Barbados	20,044	9	0
Grenada	6,359	19	11
St. Vincent	16,072	16	8
St. Lucia	12,731	17	8
Dominica	15,120	14	5
Montserrat	6,911	16	11
Antigua	10,329	19	1
St. Kitts-Nevis	12,341	8	5
Virgin Islands	6,692	6	4
Leeward Islands Federal	15,089	13	5
Total grants	131,376	6	2

These amounts are exclusive of the expenditure upon the central establishment.

The creation of the Imperial Department of Agriculture and its assistance in directing the affairs of the botanical establishments which had been evolved in the several colonies, had the important effect of causing these institutions to be regarded definitely as agricultural departments, and not merely as botanical institutions. The change of outlook is important, for it implies that the departments are now expected to have regard to all that pertains to agriculture in the respective colonies; the work is expected to extend much beyond the introduction of new plants and the making of suggestions for their application in possible new industries; it is expected to take into consideration all this, together with the ability to advise concerning the cultivation of staple crops and the manufacture and manipulation of agricultural products, to have regard to general agricultural economics, and to give consideration to matters of education in so far as these have a bearing on the welfare of agricultural communities. This changed outlook affected the relationship between the agriculturists and the officers of the departments; there has resulted greater intimacy in their relations and more effective and continuous interchange of ideas and opinions, so that the work of the departments has influenced in a marked degree the agriculture of most of the colonies.

But beyond that there has been the important effect on the several governments, which now recognise more thoroughly than before that agricultural matters form an important, integral part of colonial administration, and that the maintenance of agricultural departments is as necessary as the maintenance of other departments, such, for example, as those concerned with public works or public health.

The work of the Imperial Department of Agriculture has thus two principal phases: it is concerned with the affairs of the larger colonies, British Guiana, Trinidad, and Jamaica, in so far as its availability for advice in a general capacity is concerned. The connection with the smaller colonies is more intimate, and the Department exercises a more detailed and general supervision in agricultural matters in these colonies. It is understood that each of the larger colonies is able to maintain a scientific staff, including such technical officers as chemists, entomologists, mycologists, botanists, and others, and is able to deal with its own scientific problems in detail. The case is different in the smaller colonies, for the cost of providing such fully-equipped staffs in each of these islands would create a disproportionate charge which the revenue would be unable to bear.

To meet these conditions, scientific officers are maintained on the staff of the Imperial Department of Agriculture. These officers are ordinarily resident in Barbados, but they travel as occasion demands. To them is entrusted the investigation of such matters as transcend the scope of the activities of the officers of the local departments. To a considerable extent these officers have been concerned in investigating the several plant pests and diseases which are of fundamental importance to agriculture in the tropics, and which cause serious losses and retard progress in the islands concerned, even to the extent, in some instances, of making it impossible to carry on the cultivation of certain crops unless the pests and diseases can be adequately and economically controlled. Reference will be made later to some of the main features of the lines of activity here outlined.

Agricultural activity was thus stimulated in all the West Indian colonies; the greater extent of the scientific work, the increased number of investigators, the interchange of ideas and opinions, produced their natural effect, so that increased scientific activity in relation to agriculture was soon observed in all the colonies, both large and small. The activities of the Imperial Depart-

ment thus reacted on the colonies of British Guiana, Trinidad and Jamaica, as well as on the smaller colonies.

As the Imperial Department is more intimately concerned with the details of development in the smaller colonies, it will be convenient now to centre attention more particularly upon some of the work done in these smaller islands, as exemplifying the results attained through the application of scientific principles to agricultural administration, using this expression in the broadest sense so as to include the functions of general government as well as the activities of the agricultural officers and the planters.

It is necessary to understand what are the salient industries of the different islands. To quote the Report of the West India Royal Commission of 1897, p. 3, "the prosperity of the West Indies in former times was mainly due to sugar and rum; the production of these commodities attained such dimensions as to dwarf, and at one time, almost to extinguish, every competing industry." Sugar production remains the principal industry of Barbados, Antigua, and St. Kitts, and constitutes an important item in St. Lucia. Up to quite recent times it was the main industry of Grenada, St. Vincent, Montserrat and Nevis, and was carried on in Dominica and the Virgin Islands. Of late the cultivation of cacao has succeeded that of sugar in Grenada, and to a smaller extent in St. Lucia and Dominica. The cultivation of limes is now the principal industry of Dominica, and one of considerable importance in Montserrat and St. Lucia. In St. Vincent the cultivation of arrowroot holds an important place, while quite recently, and largely as the outcome of the work of the Imperial Department of Agriculture, cotton has become the principal industry of St. Vincent, Montserrat and Nevis. Cotton is also important in St. Kitts, and to a lesser extent in Antigua and Barbados, while it has become of value to the peasant cultivators of the Virgin Islands.

With the establishment of the Imperial Department of Agriculture, and its financial assistance to maintain the local departments, a good deal of interest centred in sugar production. Experiment stations for the study of field problems had already been established in several of the islands; increased financial assistance was forthcoming for these, and their work was extended. Problems relating to the manuring and the cultivation of sugar-cane were investigated and some useful points elucidated; the work of producing new seedling sugar canes, which had been successfully carried on in Barbados for some years, was extended, new seedlings of promise were distributed to other islands, and on a smaller scale the work of producing new seedlings was undertaken in Antigua and St. Kitts. Here it should be stated that there was much activity on the part of the Agricultural Department of British Guiana in the production of new seedling canes and in the study of their characters, and also in investigating the manurial requirements of the sugar-cane and in studying certain soil problems, some of them of peculiar difficulty.

Much activity was centred in investigations concerning the pests and diseases of the sugar-cane; this aspect of the work was highly appreciated, for in the period about 1895–7 an outbreak of a virulent fungus disease, now known to be due to *Colletotrichum falcatum*, caused the almost complete extinction of the Bourbon cane, the variety then most extensively cultivated, and gave the gravest alarm to sugar-growers, who feared the total loss of their industry. Relief from the trouble was found in the fact that some of the varieties cultivated in the experiment stations—some of which had already passed into general cultivation—were found to be resistant to this disease, so that the danger was arrested by the general adoption of these resistant varieties. It will be readily understood that some time and effort were expended in ascertaining and demonstrating these facts, and that while this work was in progress grave anxiety prevailed amongst the growers of sugar. This position caused additional attention to be centred upon the production of new seedling sugar-canes, with a view to securing resistant canes with a maximum yield of sugar.

It may be claimed that the various pests and diseases of the sugar-cane, together with the means of controlling or mitigating them, are now fairly well understood. Some work still remains to be done in this direction, and this continues to engage the attention of the scientific officers.

As the outcome of all these efforts, the sugar-growers in the several islands are informed concerning the main principles involved in the cultivation and manuring of their canes and in controlling the pests and diseases to which they are exposed. They thus carry on their operations with a greater sense of security, a security which is felt to be all the safer from the knowledge that in their midst there is a body of men whose function it is to watch carefully for approaching danger and

devise means for fighting it. It is only right that attention should be drawn to the fact that in this and similar work many of the planters themselves have co-operated, and by their co-operation have hastened the progress of knowledge.

In addition to giving consideration to field work connected with sugar, the creation of the Imperial Department, with its financial assistance to the associated departments, made it possible to extend attention to factory problems. Up to the time of the creation of the department, the manufacture of sugar in all the smaller islands, including Barbados, was carried on in small factories making muscovado sugar; that is to say, the sugar was made by means of open pans heated directly over open fires, whereby a soft, brown sugar having relatively small crystals was made. An important and intrinsic defect of these small factories was that the mills used for crushing the canes were, as judged by modern standards, small and inefficient; they had but three rollers, and were capable of expressing only about 50 to 60 per cent. of juice from the canes, or even less in the case of very bad mills, such as existed in some of the islands; this would be equivalent to about 62 to 75 per cent. of the juice contained in canes of average quality. The quantity of cane required to make a ton of muscovado sugar was not accurately known, for the canes were seldom, if ever, weighed. Such estimates as have been made place the amount at some 13·5 to 14 tons of cane per ton of sugar under moderately favourable conditions, but in badly-equipped works the amount must have been greater. The actual amount would, of course, depend on the quality of the cane, which varies. In this connection it must not be forgotten that a certain amount of molasses was produced in conjunction with the muscovado sugar; the value of this varied, the product at times selling at good prices, at others being disposed of with difficulty. Still, on the whole, it was an important factor in the muscovado sugar industry.

For many years there had been much discussion with regard to adopting improved methods of sugar-making, for muscovado sugar was being disposed of with increasing difficulty; the refiners, who purchased by far the larger part of it were showing marked preference for the types of sugar produced in vacuum pans. Some attempts had been made to adopt modern methods in British Guiana and Trinidad, but in Barbados, Antigua, and St. Kitts this effort had gone little beyond the introduction of vacuum pans in a few cases; the mills still remained of the inefficient three-roller type. In spite of much discussion little progress was made.

The inadequacies of the muscovado system, and the necessity for the adoption of the methods of modern factories, were the subject of much consideration on the part of the agricultural departments in the Leeward Islands, particularly in Antigua, and at last the Antigua Sugar Factory Co. took advantage of a favourable opportunity that occurred and created a sugar factory on modern lines at Gunthorpes in that island. In order to secure the erection of this pioneer factory and to ensure that its results should be available for the guidance of others similarly situated, financial assistance was given by the Government to the extent of £15,000. The factory as originally put down was a very modest affair, but its work was conducted on strictly scientific lines, and the results, including the figures obtained in the factory and its laboratory, were regularly submitted to the Agricultural Department, which in turn rendered considerable assistance in the way of scrutiny and advice.

It was soon found that the general ideas with which the factory was planned were sound, but that much more had to be done in order to make it really efficient when judged from modern standpoints. Seeing that those who had embarked on the enterprise soon felt confidence in their venture, for it was under scientific supervision and its capabilities were becoming apparent, progress was steady and rapid. Time will not permit of anything like a detailed survey of the development of this factory; suffice it to say, that from the first crop of 1,634 tons manufactured in 1905, and 2,349 tons in 1906, the output of the factory had grown to 12,371 tons in 1916, the output for the succeeding years being somewhat smaller on account of drought and adverse growing seasons, which restricted the production of canes.

The progress of the factory can be measured from one or two salient figures; in the early days of the factory's working only some 65 per cent. of the sugar in the cane found its way to market in the form of commercial sugar, whereas in the later years this has reached 88 per cent.; refiners' crystals of 96° polarisation being made. This constitutes a gain in production of twenty-three on the hundred parts of sugar in the cane, but it is over 35 per cent. on the 65 per cent. recovery of the earlier years. At the same time

the quantity of cane taken to make a ton of sugar was reduced from about 9¾ tons to about 8¾ tons, a comparison which is, however, less accurate and of less importance on account of the varying nature of the quality of the canes. It should be added that a fourteen-roller mill was installed in the factory in 1911, and to this much of the improvement in recovery is due.

The Gunthorpes factory has thus served to demonstrate the possibilities of modern sugar-making in small places, and it has shown that a high degree of efficiency can be secured in what must, according to modern ideas, be regarded as quite a small factory. It may be well to state at this point that a factory of this size probably represents the limit of smallness for efficient working. The tendency is towards much larger factories, even to ten times the capacity of Gunthorpes.

It is worth noting in passing that this factory is based on co-operative principles under which the assistance of outside capitalists was invoked, and they entered into contracts with the owners of sugar plantations to supply canes on a profit-sharing basis for a period of fifteen years; at the expiration of this time, during which the debentures representing the principal portion of the capital of the venture were being repaid, the original contracting plantation owners received shares from the factory equal in number and value to the original capitalists' shares. It should be added that in the process of the expansion of the factory it was joined by other contractors who do not enjoy the same privilege.

The period of the fifteen years of the original contract has now expired, and the distribution of the shares to the original contracting proprietors will have been made by the time this paper has been read.

It is satisfactory to note that this contract, which included some features unfamiliar to previous West Indian experience, has worked without a single hitch, and that the factory was paying its way and demonstrating its economic soundness with the low prices of sugar that were realised prior to the war. The high prices obtained for sugar, as the result of the sugar shortage caused by the war, have added considerably to the profits, but the soundness of the principles on which the factory was founded and the relief which these were capable of affording to the sugar industry of the West Indies were demonstrated under pre-war conditions.

The influence of the Antigua sugar factory was not confined to that island, the information gained in its operation being widely disseminated and thoroughly discussed, as was the intention of the Government in giving it financial aid; in consequence of this the development of similar factories was considered in other islands. As the outcome, a well-equipped factory was established in St. Kitts, reaping its first crop in 1912. This factory is financed by the same group of capitalists as the Antigua one and is operated on very similar principles with slight modification. The St. Kitts factory has manufactured as much as 11,843 tons in a single season.

Encouraged by the success of the factories in Antigua and St. Kitts the same group of capitalists purchased in 1913 the large sugar factory in Trinidad, known as the Usine Ste. Madeleine, with the plantations connected with it. This concern was in financial difficulty and its future was very obscure. The knowledge gained at Antigua and St. Kitts proved of the greatest service and the working of the factory was soon put on a sound footing. This, coupled with some good fortune and the improvement of the sugar position, has resulted in considerable financial success, which has been greatly to the benefit of the colony.

The progress of events connected with the Antigua sugar factory, aided by the publication and discussion of the results obtained, was followed closely by the plantation owners of Barbados. In a short time substantial improvements were made in the small sugar factories of this colony and several small factories were established, embodying modern methods of sugar production, including the adoption of multiple crushing of the canes in the mills. Notwithstanding the fact that these factories are for the most part quite small, when judged by modern standards, they are reasonably efficient, since, as a rule, they have been evolved out of factories already in existence, and it has been possible in the majority of cases to effect the developments economically and with local capital. These small factories are in a very strong position, though it is probable that as developments ensue there will be amalgamations whereby larger factories will result, which will admit of greater efficiency and diminished cost in production. The present effect, however, is that a very large proportion of the sugar of Barbados is to-day manufactured in factories turning out refiners' crystals in place of the old and wasteful muscovado sugar, by which the prosperity of the colony has been greatly

enhanced and the situation much improved as regards the supplying of sugar during the stress of war.

It will generally be admitted that the central sugar factory established at Gunthorpes has amply fulfilled the expectations of its promoters. The effect of its successful working, coupled with full dissemination of the results of its operation, including statements of the methods employed and their cost, has reacted notably on the sugar industry of the British West Indies. Few Government investments have been more productive of good than the £15,000 contributed to that factory scheme by the wise prevision of the then Governor of the Colony, Sir Gerald Strickland.

Other matters besides sugar have had attention on the part of the Imperial and associated Departments of Agriculture.

In connection with cacao there has been much study of the pests and diseases to which this crop is liable, and material progress has been made in unravelling the complex stories which these troubles present. These matters cannot be dealt with in detail here; they are referred to at length in various departmental publications.

Attention, too, has been given in the experiment stations and on the estates of private owners to questions related to the planting, cultivating, and manuring of cacao trees, together with some consideration of the varieties grown. In this way information of a useful character has been gathered and disseminated concerning the manurial requirements of the cacao tree, the budding and grafting of cacao and the handling of cacao plantations generally. While much has been done, this field of work still presents many problems of interest, particularly in regard to the preparation of the cacao bean for market and the meeting of the requirements of the manufacturers of chocolate and cocoa.

Similarly, much work has been done in connection with the lime industry. The pests and diseases affecting lime trees have been carefully studied; the methods of cultivation and manuring of lime trees have been investigated, and also the preparation of lime products for market. In this last connection much has been done to improve the preparation of concentrated lime juice, the principal product of the lime, which finds its way into a number of manufacturing industries, notably for the preparation of citric acid and in dyeing and calico printing. Assistance was given in demonstrating the method of making citrate of lime which is used in the manufacture of citric acid. A comprehensive handbook has been published giving information concerning the cultivation and treatment of lime trees and the manipulation of their products.

In recent years an experiment station devoted to the cultivation of limes and the investigation of the problems incident thereto has been established in Dominica, and already many valuable lessons have been learned from it.

In connection with the work of the St. Lucia Department of Agriculture, a factory has been established for the purchase of limes on a profit-sharing basis and the preparation from them of essential oil and concentrated lime juice. The object of this venture was to encourage the planting of limes in that island and to afford a means of disposing of the fruit to those whose cultivation is too small to warrant the erection of the machinery required for its manipulation; at the same time the facilities thus offered are of material service to the larger cultivators in the earlier stages of their enterprise, for they can dispose of the small quantities of fruit which mature in the first few years of the growth of their trees, and thereby defer the expense of erecting machinery until they are in possession of sufficiently large crops to warrant the required outlay. This factory is equipped with steam-boiling plant, the use of which had been advocated departmentally for years, but which had been adopted by large growers in only a few instances. In the operation of this factory much valuable information has been acquired, for careful account is kept of the various operations; it has been demonstrated that by concentrating lime juice by steam heat the loss of citric acid by burning can be reduced to quite low limits, whereas, when the concentration is carried on over open fires, as was formerly the method commonly in vogue, the loss is frequently very large, and, in cases where the work is conducted carelessly, it may be disastrously so. As the outcome of this demonstration and the publication of the information thus made available, the introduction of steam-heated plants has become fairly general. By the use of such apparatus the quality of the product is considerably improved, so that it is capable of direct use in calico printing.

The operation of the St. Lucia Government lime-juice factory proved a great stimulus to the development of the lime industry in that colony and, incidentally, led to much greater attention being given to agricultural matters

there, so that important results followed from a simple expansion of departmental activity.

Something might be said concerning the work done in connection with crops which can hardly be regarded as staple industries, but which have local significance. For example, attention has been given to the production of maize, a matter of importance, for such maize is consumed as corn meal in all the islands. It really constitutes one of the principal foods of the people. The necessity for producing food during war conditions and even now, with production and shipping difficulties has stimulated this work. Corn driers and mills for the production of meal were erected in Antigua and in St. Vincent, the granaries thus created being operated by the agricultural departments, corn (maize) being purchased on profit-sharing lines and meal or grain sold for local consumption. This work stimulated production, not only on the part of those who sold their corn to the granaries, but also on the part of those who grew it for use on their own plantations, for the fear of loss of the grain from its becoming mouldy, due to insufficient drying in a damp climate, deterred many from growing maize. Now, with the assistance of central drying appliances by which grain can be dried at a small charge, a sense of security results and production is increased.

The Government granary at St. Vincent has been particularly successful and instructive. Through its operations a large proportion of the corn and corn meal consumed in the colony is now produced locally. A further interesting step was taken at this granary during the war; a small storehouse was built in which perishable commodities such as corn, rice, and peas, were stored under conditions whereby they were kept free from insect attack, after treatment, if necessary in the grain drier. This is of considerable convenience to dealers, for great difficulties are often experienced in storing commodities of this nature. The granary at Antigua has been less successful than that at St. Vincent.

Amongst other efforts to encourage minor industries, reference may be made to what has been done with onion-growing. Work was taken in hand, chiefly in Antigua, to ascertain whether onion-growing would be possible in these islands. The difficulties were investigated, and correct methods of practice were developed, so that, after some years of work and many interruptions and discouragements, an onion industry of moderate proportions has now been secured, mainly in Antigua, but with extension to some of the other islands. One interesting feature of this work is that the greater part of the onion crop is handled through the Onion Growers' Association, on a co-operative and profit-sharing basis. In developing matters to this point, much patient work was done by departmental officers in studying conditions of cultivation, the provision of the best type of seed, the control of pests and diseases, and the handling and marketing of the crop.

[*The second part of the paper and the Discussion will be printed in the next number of the "Journal."*]

THE PAPER INDUSTRY IN JAPAN.

The manufacture of paper has been carried on in Japan for many centuries. The product now generally known as Japanese paper was described by the early Dutch traders nearly 250 years ago. This product has served all the uses to which we put paper—book printing, covering for doors and partitions, writing and wrapping—and, in addition, has been utilised by the Japanese as a substitute for string, cloth, oilcloth, leather, and even wood, iron and glass. Its excellent lasting qualities and its superiority over machine-made papers have led to its utilisation for a number of purposes for which foreign paper would be unsuitable. These advantages are due to the fact that in making this paper the Japanese use the tough and pliant inner bark from three or four species of deciduous trees, possessing long, tough, fibre cells, and this bark is not cut or hacked in transforming it into pulp, but is separated by pounding and beating, so that the long cells remain unbroken.

In the manufacture of this paper the form is held so that the parallel splinters or threads run from left to right. The form is then lifted and lowered at right angles to this direction, causing the fibres of the material to lie in one direction. Japanese paper is consequently torn easily one way, but with difficulty the other. There is no special sizing or glazing, but each sheet has a rough and smooth side, resulting from the process of drying. The shaped sheets are pasted with a large brush on a smooth planed board to dry, and the side against the board remains much smoother than the outside surface. The smooth side is used for book printing and the two rough sides are folded against each other in binding the book, so that Japanese books consist of double sheets of thin paper.

From an interesting monograph on the paper industry in Japan, prepared by the Far Eastern Division of the U.S. Bureau of Foreign and Domestic Commerce, and from which the foregoing particulars have been taken, it would appear that all Japanese paper is very porous, and consequently cannot be written on with pen and ink, although

it is well adapted to the Japanese mode of writing with brush and india ink. Smooth, firm, machine-made paper would not absorb this ink so well, and is therefore not in demand. There is no bleaching, and all Japanese paper is of a yellow tint, although sometimes whitened by the ingredients used to soften it in manufacture.

Paper produced in Japan may be divided into two general kinds—Japanese paper as described above, and foreign or machine-made paper. Aside from the nature of the product, the two industries are further distinguished by the fact that the former is largely a household industry, and the latter a factory industry. The production of the Japanese paper in 1916 is officially valued at over £2,500,000; no figures as to quantity are available.

The principal raw materials entering into the manufacture of Japanese paper are the inner barks of the paper mulberry trees (*Broussonetia papyrifera*, *Edgeworthia papyrifera*, *Wickstroemia canescens*—a small bush related to the spurge laurel, *Morus alba*—white mulberry tree) and the *Aphananthe aspera*. The classes of paper produced from these materials are broussonetia papers, made from kodzu fibre; edgeworthia papers, made from mitsu-mata and from a mixture of mitsu-mata and kodzu; wickstroemia papers, made from the bast of morus alba; and suki-gaeshi papers, made from old or used papers.

The names of the various kinds of paper of each class, the province where made, the size of the sheets, and the number of sheets and the weight per quire, are given on p. 227.

Japanese papers derive their names almost exclusively from the towns or districts where they were originally made, and this geographical distinction perhaps accounts to some extent for the difference in grades. A short description of each of those figuring in the export trade is given below:—

Yoshino, manufactured in the town of Yoshino, in Yamato Prefecture, is a fine paper, used extensively in the lacquer industry. The mould is a net made of finely wrought bamboo sticks bound together with silk thread, and the texture of the product is indicated by the figures in the following table, one quire (50 sheets), or about 6·12 square metres, weighing only 35 grammes. The paper is so firm, however, that two or three layers used to filter thick lacquer are not only uninjured by the wringing and pressing through of the lacquer, but are afterwards smoothed out, dried, and used several times over for the same purpose.

Tengujo, literally "prize-crowned-labour," excels in fineness and pliancy the thinnest silk papers, and is also much stronger. It is manufactured in Mino Province, and is extremely well adapted for pasting on common window panes to make them opaque.

Mino is pure broussonetia paper made in the Province of Mino, and is noted for its firmness. It is used for covering woodenwares in the process of lacquering, for cord, and as a covering for the lattice of sliding doors, as it is very transparent. The 1916 production was 275,293 reams.

Hanshi, literally "half-paper," is so-called because of its common use in book manufacture, where only half the sheet is used, the rough surface being turned in. Its widest uses are for writing, printing, and paper handkerchiefs. Production in 1916 amounted to 3,266,195 reams of 100 quires (6·12 square metres) each.

Usuyo, or gampi, is at present used largely abroad as a copying paper in business houses, although its pliancy, smoothness, strength, and lightness will probably find other uses for it, as it becomes better known.

Torinoko is a semi-foreign paper which resembles parchment, and has enjoyed an increased sale abroad, especially in China, as a substitute for foreign parchments.

Renshi, literally "ream paper," is an imitation of the Chinese-sized papers put up in the same quantity, and is sold almost entirely in China.

Toyoshi, "Far East paper," is also sold almost exclusively to China, where it is used for a variety of local purposes.

Other varieties of Japanese paper, which do not figure in the export trade, but which are used largely in Japan, include the following:—Hankiri, resembling hanshi, used for account keeping and letter writing; nishi-no-uchi and shi-fu-gami, made from broussonetia bark in very large sheets, are exceedingly strong, and are used as a fabric; atsu-gami and senka are very thick strong papers used in making imitation leather and oil papers; another heavy, starched paper, ko-sugi, is cheaper, and is used for cleansing purposes; iyo-masa is a soft paper, and is well adapted for wrapping dried plants; hosho, one of the most valuable and expensive Japanese papers, is thick, very strong, of even texture and gloss, rich in starch, and often contains alum. It is used as the Government paper for all important legal acts, as a wrapping paper for expensive presents, and was formerly used for making paper-money. It is made in the celebrated five villages of Hoshi district in Echizen Prefecture.

Ju-mon-ji and jidzuki, otaki-gami, are large sheets of very thick, stout paper, used principally in the preparation of leather paper.

Suruga-ban-shi is a thin writing paper, and is also used for cleansing purposes and printing.

Shoji-gami contains about 20 per cent. of Edgeworthia pulp, and serves principally as the covering for lattices or shoji (sliding doors) and as a substitute for window-panes.

Ita-me-gami, or board paper, is made by fastening together, with wheat-starch paste, a number of sheets of common paper. This pasteboard is frequently made from waste-paper, old business documents, and other used paper, covered with a coating of fresh paper of good grade.

Papier-Mâché.—Hari-nuki, or Japanese papier-mâché, is also prepared from waste paper, but the process differs in that the hari-nuki is not prepared from paper reduced to pulp after being soaked in water, as is papier-mâché, but is made like pasteboard, the couching being done on wooden forms.

Name of Paper.	Province where made.	Size of Sheets.	Sheets per quire.	Weight per quire.
Broussonetia Papers:		Centimetres.	Number.	Grammes.
Yoshino-gami	Yamato	48 × 25·5	50	85
Mogami-gami	Uzen	31 × 27·5	50	25
Tengu-jo Pure	Mino	39 × 27	48	56

Suki-gae-shi Papers:				
Chiri-gami, grey	Musashi	40 × 26·5	50	150
Suka-gae-shi, best quality, grey-white	do.	31·5 × 26·5	50	75

Sheet after sheet of light waste paper is stuck with wheat-starch paste, and spread out over the form until the required thickness is obtained. The board is then cut, dried, and lacquered, and many small durable articles are made from it, such as dolls' heads, plates, saucers, tea caddies, and pipe cases. These articles closely resemble lacquered wood and far excel papier mâché in firmness and elegance. They are strong, durable, and surprisingly light and cheap. Kara-kami, or paper for hanging, is made in sheet size in a very small quantity, owing to the light demand.

Crêpe Paper.—By means of two very simple wooden tools—a lever press and mould—the smooth surface of several bark papers is twilled, and stiff cardboard is made soft and pliant, and given a surprising elasticity. The lever press is made either of evergreen oak or some other hard-wood, and stands on a foundation consisting of a large, heavy board, through which two perforated posts are fastened as tenon bearers, and between which lies the fulcrum of the lever. The moulds are large sheets of thick brown paper, which are grooved in parallel furrows in several directions, and show considerable elasticity when moistened. The paper to be twilled is wrapped around a wooden cylinder, varying in diameter from 2 to 3 inches, and in length according to the size of the paper, which also determines the height to which the tenon for the fulcrum of the lever is raised.

The sheets are moistened by sprinkling, and subjected for an hour to a mild pressure between alternate layers of wet paste-boards. The moistened sheets are then placed over the moulds about ten thick, and another mould placed on top. In this arrangement of layers the single sheets must lie even with the separating sheets, and have their edges parallel to those of the moulds. These layers

are wrapped tightly around the cylinder, making it about 6 or 8 inches in diameter. The cylinder is then diagonally wound round with a strip of hemp canvas and placed in the press, where pressure is applied by six or eight jerks on the roll, which is compressed in the direction of its axis. It is then taken out, and the thin sheets removed and placed on the forms or moulds in another position. After this process has been repeated eight or ten times in different positions, the paper is considerably smaller in length and width, but is stretched somewhat before being used. With each new operation the markings from the moulds become constantly finer and more regular, and shrinkage of the sheets and increasing softness and pliancy accompany this transformation.

Leather Paper.—Japanese leather paper is very soft, has great elasticity, and resembles calf leather. It is used in the manufacture of leather portfolios, tobacco bags, pipe cases, boxes, small chests, and other articles, and also as a floor covering, and as a protection from rain over wooden shoes. The paper is admirably adapted for hanging in salons. The process of manufacture is briefly as follows:—

1. The paper to be treated is spread out on a board, the smooth side up, coated with thin rice paste, to which lamp-black has been added, and then hung on horizontal poles to dry for several days.

2. The twilling is done by the same process employed in making crêpe paper.

3. A coating of perilla-seed oil is applied, and it is allowed to dry in the sun from five to twenty days, according to the time of the year.

4. A coating of paste solution mixed with the dye to be used, generally red oxide of iron, orpiment, indigo, india ink or other dyes, is put on.

5. When dried the paper is impregnated with lacquer by two workmen sitting opposite each other, who smear their hands with lacquer and beat them quickly on the sheet, after which it is dried on a frame.

6. If the leather paper is to be figured, carved wooden moulds are pressed in at the close of the crêpe process, and the colours applied by paper stencil plates. A metallic reflecting surface is obtained after the figures are made by fixing bronze powder with lacquer, and polishing when dry. Some papers are dried in the smoke of rice straw and then rubbed.

Paper Fabric.—The warp of Japanese paper fabric consists of silk threads and the woof of paper threads, made of broussonetia fibre. To make these threads, the paper is laid lengthwise over the narrow side of a thick board, provided with feet to lend it stability, and fastened at both ends with iron clamps. It is then cut into strips, long ribbons being produced by cutting the paper not quite to the end. These are rolled into thread on a stone slab by hand. The connecting edges are cut on both sides so far through that the single threads hang together by a width of only ¼-inch, and these connecting places are twisted to form a continuous thread.

In making paper fabric for clothing, the threads are twisted from right to left, like those of the silk woof for crêpe silk, and run in the fabric alternately, two right-twisted woof threads following two left-twisted ones. When finished the fabric is washed in boiling straw-ash lye, dried, and stretched. It acquires in this process an appearance of being twilled and is shrunk considerably. It is then dyed in various patterns. 150 years ago this fabric was very popular in Japan for women's summer clothing, but the more durable cotton fabrics have supplanted it at a much lower price, and now only a few small factories engage in the industry.

Oil Paper and Waterproof Paper.—Oiled papers are made for two purposes in Japan, one for use as transparent paper in lanterns, etc., and another for protection against water, as for umbrellas, and regular oil and leather paper. For this product perilla-seed oil is invariably used, and broussonetia paper of a stout grade is generally employed. The paper is made pliant, either by kneading, or by the crêpe process already described, and is pasted in the thickness desired with glue or paste made from the flour of the common brake. The sheets are then treated with a mixtnre of lamp-black (for black waterproof cloaks) and the juice of unripe persimmons, and dried in the sun for five days. Two coats of perilla-seed oil boiled with persimmon juice are then applied, drying taking place between the applications. The entire process requires about 15 days in good weather. Though far inferior in appearance and durability to oilcloth and western waterproof cloth, oil paper has served its purpose in Japan for several hundred years.

Since the oiled Japanese paper umbrella could not be used as a sunshade, nor the unoiled variety as a protection from the rain, the adoption of the silk umbrella, suitable for all weathers, has been rapid, and the Japanese manufactured silk umbrella is one of the few foreign articles used generally throughout the interior as well as in the large cities.

Foreign and Machine-made Paper.—The total production of European, foreign or machine-made paper in Japan in 1916 amounted to 558,588,246 lb., as compared with 197,506,826 lb. in 1907. The paper produced in 1916 was made in 51 modern mills, representing a total capital of more than £3,000,000. There has been a steady increase in production in recent years, as a result of which the imports of every variety of paper have decreased considerably, and there is reason to believe that the industry is firmly enough established in Japan to withstand any foreign competition. This is especially true of those kinds of paper, the output of which is on a large scale, and in the manufacture of which the Japanese are organising for scale production by concentrating the industry on modern lines in the hands of one or two large companies.

GENERAL NOTES.

Canals and Inland Waterways. — In the House of Commons on February 16th Mr. Neville Chamberlain, in a question addressed to the Minister of Transport (Sir Eric Geddes), asked whether he was yet in a position to state the policy of the Ministry as to the future ownership and administration of canals and inland waterways; whether he was aware that the revised railway rates were likely to have the effect of driving heavy and bulky traffic off the water on to the railways, and whether he would cause a further revision to be made with a view to the distribution of traffic between railways and canals. Mr. A. Neal (Parliamentary Secretary of the Department) said that Sir E. Geddes was proposing to appoint a Committee, of which he hoped Mr. N. Chamberlain would consent to be Chairman, "to consider what development of canals and waterways is practicable, having regard to the financial position at the moment." In answer to a supplementary question, Mr. Neal said it was not the fact that the whole of the canals, or the majority of them, were owned by the railway companies. Mr. Macquisten said the key ones were. Mr. Neal, replying to another question, said that to carry out in its entirety the report made by the Railway Commission would involve the expenditure of many millions. Before advising the House to sanction such an expenditure Sir E. Geddes desired to be fully advised upon the question in its present relationship to all transport problems.

Coal in the United Kingdom, 1918.—The total output of coal in the United Kingdom in 1918 was 227,748,654 tons, and the value £238,240,760, showing a decrease in the output of 20,750,586 tons and an increase in the value of £30,453,866 on the figures for 1917. The average price of coal was 20*s.* 11·06*d.* per ton in 1918 as compared with 16*s.* 8·68*d.* in 1917. The quantity of coal exported, exclusive of coke and manufactured fuel and of coal shipped for the use of steamers engaged in foreign trade, was 31,752,904 tons. France received over 16½ million tons, Italy over 4 million tons, Egypt nearly 1¾ million tons, Gibraltar over 1½ million tons, Norway over 1¼ million tons, Malta nearly 1¼ million tons, and Sweden and Denmark each over 1 million tons. The amount of coal remaining for home consumption was 184,358,158 tons, or 4·385 tons per head of the population.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday afternoons, at 4.30 p.m. :—

February 25. — James Currie, C.M.G., Ministry of Labour (Training Department), late Principal, Gordon Memorial College, Khartoum, "Industrial Training." The Right Hon. Sir Robert S. Horne, K.B.E., K.C., M.P., Minister of Labour, will preside.

March 3.—William James Garnett, First Secretary, H.B.M. Diplomatic Service, "Mongolia from the Commercial Point of View."

March 10.—H. M. Thornton, "Gas in relation to Industrial Production and National Economy." Sir Robert A. Hadfield, Bt., D.Sc., F.R.S., will preside.

March 17. — William Worby Beaumont, M.Inst.C.E., "Street Passenger Transport of London."

March 24.—L. Gaster, "Industrial Lighting in its relation to Efficiency."

April 14.—Joseph Thorp, "The Fundamental Basis of Good Printing."

April 21.—Air-Commodore Edward Maitland, C.M.G., D.S.O., A.F.C., "The Commercial Future of Airships."

April 28.—Charles H. Sherrill, "Stained Glass."

Indian Section.

Friday afternoon, at 4.30 p.m. :—

March 19.—Sir William S. Meyer, G.C.I.E., K.C.S.I., Financial Member of Council of the Governor-General of India, 1913-18, "The Indian Currency System and its Developments." The Right Hon. Lord Chalmers, G.C.B., LL.D., will preside.

Thursday afternoons, at 4.30 p.m. :—

April 15.—Brigadier-General Lord Montagu of Beaulieu, C.S.I., "Roads and Transport in India."

May 20.—Sir George Cunningham Buchanan, K.C.I.E., M.Inst.C.E., "The Ports of India: their Administration and Development."

Date to be hereafter announced :—

Sir Valentine Chirol, "The Enduring Power of Hinduism." (Sir George Birdwood Memorial Lecture.)

Colonial Section.

Tuesday afternoons, at 4.30 p.m. :—

March 2.—G. F. Scott Elliot, M.A., B.Sc., F.R.G.S., "Trade Routes for the Empire in Africa." Colonel Sir Thomas H. Holdich, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., will preside.

May 4.—Professor William A. Bone, D.Sc., Ph.D., F.R.S., "Lignite."

Indian and Colonial Sections.

(Joint Meeting.)

Date to be hereafter announced :—

Professor Sir John Cadman, K.C.M.G., D.Sc., F.G.S., M.Inst.C.E., "The Oil Resources of the British Empire."

Dates to be hereafter announced :—

GRAILY HEWITT, "Rolls of Honour."

CHARLES CROWTHER, "The Arts and Crafts of Japan." (with examples from the author's private collection).

WILLIAM CRAMP, D.Sc., M.I.E.E., "Pneumatic Conveying Plants, with special reference to the Transport of Grain."

CANTOR LECTURES.

Monday evenings, at 8 p.m. :—

CHARLES FREDERICK CROSS, B.Sc., F.R.S., F.C.S., "Recent Research in Cellulose Industry." Three Lectures.

Syllabus.

LECTURE II. — FEBRUARY 23. — *The Cellulose Industries.* Cotton-spinning — Investigations of factors of process and qualities of products—Raw cotton and (normal) bleached cotton—Artificial silk, controlled hydration of celluloses by chemical process and a critical re-investigation of paper-making processes—Twisted paper yarns.

LECTURE III.—MARCH 1.—*Cellulose and Derivatives.* Nitrates—Acetates—Progress of research and industry—Specific volumes of cellulose and hydrates—Data of fundamental importance, scientific and industrial—The problems of constitution.

WALTER ROSENHAIN, B.A., D.Sc., F.R.S., Superintendent, Department of Metallurgy and Metallurgical Chemistry, National Physical Laboratory, "Aluminium and its Alloys." Three Lectures.

April 12, 19, 26.

ARTHUR THOMAS BOLTON, F.R.I.B.A., F.S.A., Curator, Soane Museum, "The Decoration and Architecture of Robert Adam and Sir John Soane, 1758–1837." Three Lectures.

May 3, 10, 17.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, FEBRUARY 23...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. C. F. Cross, "Recent Researches in the Cellulose Industry." (Lecture II.)

TUESDAY, FEBRUARY 24...Illuminating Engineering Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Dr. T. L. Llewellyn, "Lighting Conditions in Mines, with special reference to the Eyesight of Miners."

University of London, School of Oriental Studies, Finsbury-circus, E.C., 5 p.m. Mr. A. D. Innes, "The Mogul Period of the History of India." (Lecture III.)

Royal Institution, Albemarle-street, W., 3 p.m. Professor E. Wilson, "Magnetic Susceptibility." (Lecture II.)

Civil Engineers, Institution of, Great George-street, S.W., 5.30 p.m. Sir F. J. E. Spring, "Restoration of a Cyclone-Damaged Breakwater-end in Madras Harbour," and "Coastal Sand Travel near Madras Harbour."

Photographic Society, 35, Russell-square, W.C., 7 p.m. Dr. C. A. Swan, "Wanderings in Italy."

Colonial Institute, Central Hall, Westminster, S.W., 3.30 p.m. Mr. K. Fairbridge, "Australia and Child Emigration."

Horticultural Society, Vincent-square, Westminster, S.W., 3 p.m. Mr. J. Hudson, "The Cultivation of Fruits under Glass with a minimum of Fire Heat."

Industrial League and Council, Carpenters' Hall, Throgmorton-avenue, E.C., 5.15 p.m. Mr. T. E. Naylor, "Trade Unionism and Output."

Central Hall, Westminster, S.W., 7.30 p.m. Messrs. Mundy and Roe, "Profit Sharing."

Zoological Society, Regent's-park, N.W., 5.30 p.m. 1. The Secretary, "Report on the Additions to the Society's Menagerie during the month of January, 1920." 2. Mr. E. G. Boulenger, "On some Lizards of the Genus *Chalcides*." 3. Mr. N. S. Lucas, "Report on the Deaths in the Gardens in 1919: with Notes on Rickets and Avian Enteritis." 4. Mr. S. Hirst, "Revision of the English Species of Red Spider (Genera *Tetranychus* and *Oligonychus*)."

WEDNESDAY, FEBRUARY 25..ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Mr. J. Currie, "Industrial Training."

Geological Society, Burlington House, W., 5.30 p.m. Mr. H. C. Sargent, "The Lower Carboniferous Chert Formation of Derbyshire."

British Psychological Society, 8, Queen-square, W.C., 6 p.m. Dr. H. M. Vernon, "The Effect of Change in Hours of Work on Output."

THURSDAY, FEBRUARY 26...Cold Storage and Ice Association, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5 p.m. Mr. H. J. Deane, "The Development of the Cold Storage of the Port of London Authority."

Ophthalmic Opticians, Institute of, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m.

Royal Society, Burlington House, W., 4.30 p.m.

Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Dyers and Colourists, Society of, Leeds. 1. Mr. W. G. Sewell, "Sulphide Dyes." 2. Mr. N. Chappell, "Hydrosulphite."

Royal Institution, Albemarle-street, W., 3 p.m. Mr. A. H. Smith, "Illustrations of Ancient Greek and Roman Life in the British Museum." (Lecture II.)

Electrical Engineers, Institution of (Joint Meeting with the Rontgen Society and the Electro-Therapeutic Section of the Royal Society of Medicine), 1, Wimpole-street, W., 5 p.m. and 8.15 p.m. 1. Dr. R. Morton, "On the Efficiency of High-Tension Transformers as used for X-ray Purposes." 2. Major C. E. S. Phillips, "The Problem of Interrupted and Fluctuating Currents." 3. Mr. R. S. Wright, "High-Tension Transformers."

Concrete Institute, 296, Vauxhall-bridge-road, S.W., 7.30 p.m. Mr. E. F. W. Grimshaw, "Reinforced Concrete Fences and Posts."

China Society, School of Oriental Studies, Finsbury-circus, E.C., 5 p.m. Captain H. J. Hinks, "The Burmese Shan States and the Tai."

FRIDAY, FEBRUARY 27...Royal Institution, Albemarle-street, W., 9 p.m. Mr. W. B. Hardy, "Problems of Lubrication."

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Dr. F. Ward, "The Animal World Seen from under the Water."

Engineers and Shipbuilders, North-East Coast Institution of, Mining Institute, Westgate-road, Newcastle-on-Tyne, 5 p.m. Mr. G. S. Baker, "Flying Boats: the Formation and Dimensions of their Hull."

University of London, University College, Gower-street, W.C., 5 p.m. Dr. T. Borenius, "Mediæval Art." (Lecture VII.)

Physical Society, Imperial College of Science, South Kensington, S.W., 5 p.m.

Metals, Institute of (Sheffield Section), Mappin Hall, The University, Sheffield, 7.30 p.m. Messrs. E. A. Smith and H. Turner, "Standard Silver: its Production and Working Properties."

SATURDAY, FEBRUARY 28...Royal Institution, Albemarle-street, W., 3 p.m. Professor Sir J. J. Thomson, "Positive Rays." (Lecture II.)

Journal of the Royal Society of Arts.

No. 3,510. VOL. LXVIII.

FRIDAY, FEBRUARY 27, 1920.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

MONDAY, MARCH 1st, at 8 p.m. (Cantor Lecture.) Mr. CHARLES FREDERICK CROSS, B.Sc., F.R.S., "Recent Research in Cellulose Industry." (Lecture III.)

TUESDAY, MARCH 2nd, at 4.30 p.m. (Colonial Section.) G. F. SCOTT ELLIOT, M.A., B.Sc., F.R.G.S., "Trade Routes for the Empire in Africa." COLONEL SIR THOMAS H. HOLDICH, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., will preside.

WEDNESDAY, MARCH 3rd, at 4.30 p.m. (Ordinary Meeting.) WILLIAM JAMES GARNETT, First Secretary, H.B.M. Diplomatic Service, "Mongolia from the Commercial Point of View." BRIGADIER-GENERAL SIR PERCY MOLESWORTH SYKES, K.C.I.E., C.B., C.M.G., will preside.

Further particulars of the Society's meetings will be found at the end of this number.

CANTOR LECTURE.

On Monday evening, February 23rd, DR. M. O. FORSTER, F.R.S., in the chair, Mr. CHARLES FREDERICK CROSS, B.Sc., F.R.S., delivered the second lecture of his course on "Recent Research in Cellulose Industry."

The lectures will be published in the *Journal* during the summer recess.

ELEVENTH ORDINARY MEETING.

WEDNESDAY, FEBRUARY 25th, 1920; THE RIGHT HON. SIR JOHN TUDOR WALTERS, M.P., in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Aiyar, S. Paramesvara, M.A., B.L., Travancore, South India.
Cantrell, T. B., Liverpool.
Gurtu, Pundit Sri Krishen, M.A., M.Inst.C.E., Morar, Central India.
Healey, William, B.Sc., Assoc.M.Inst.C.E., Assoc.M.I.Mech.E., London.
Knox, George, F.G.S., Cardiff.
Walker, Frederick H., B.Sc., A.I.C., Newcastle-on-Tyne.

The following candidates were balloted for and duly elected Fellows of the Society:—

Barker, Sir Francis H., London.
Binns, A. S., Winnipeg, Canada.
Bowring, Edward John, Winchfield, Hants.
Cadbury, L. J., Northfield, Birmingham.
Ferguson, Louis, Port Glasgow, N.B.
James, Albert Alfred, J.P., Edgbaston, Birmingham.
Kelman, George Arthur Duff, London.
Mann, G. L. C., West Guildford, West Australia.
Mason, Rev. W. A. Parker, M.A., F.R.Hist.S., Manchester.
Mather, Right Hon. Sir William, LL.D., M.Inst.C.E., Bramshaw, New Forest.
Morris, Wing-Commander Alfred Drummond Warrington, R.A.F., C.M.G., O.B.E., London.
Naylor, Heaton, Rawdon, near Leeds.
Notley, Fenton George, Maclean, New South Wales, Australia.
Phillips, Grevile Herbert, Hereford.
Robinson, Commander Samuel M., U.S. Navy, San Francisco, California, U.S.A.
Rogers, John H., London.
Taylor, Alfred, York.
Thomas, Frank, London.
White, Tyndale, Brentwood, Essex.
Wright, Francis, Vancouver, B.C., Canada.

A paper on "Industrial Training" was read by Mr. JAMES CURRIE, C.M.G., Ministry of Labour (Training Department), late Principal, Gordon Memorial College, Khartoum.

The paper and discussion will be published in a subsequent number of the *Journal.*

COVERS FOR JOURNALS.

For the convenience of Fellows wishing to bind their volumes of the *Journal*, cloth covers can be supplied, post free, for 2*s.* each, on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

COLONIAL SECTION.

TROPICAL DEPARTMENTS OF AGRICULTURE, WITH SPECIAL REFERENCE TO THE WEST INDIES.

By Sir Francis Watts, K.C.M.G., D.Sc.,
Imperial Commissioner of Agriculture for the West Indies.

(*Continued from page* 225.)

Work connected with other industries might be described did time permit. Detailed reference may, however, be made to one industry, the establishment of which as a staple industry has been one of the marked successes of departmental work and which illustrates very completely the difficulties and complexities which have to be met in introducing a new industry. It is not sufficient to provide the seed or planting material and to point to a demand for the commodity in question: all the details of cultivation, seed production, control of pests and diseases, preparing and marketing the crop, and many others, have to be dealt with. These matters imply the work of a variety of individuals, each capable of dealing with that part of the work in which he possesses skill and knowledge.

The introduction of the Sea Island cotton industry, and its development to such a position that the welfare of more than one West Indian community now depends upon it, may be worth recording. When sugar-growers were at their wits' end to know what crops to cultivate in view of the losses which they were incurring over sugar production and the threatened extinction of the sugar industry, attention turned to cotton, which had been cultivated in the West Indies in former days. Some experiments in cotton cultivation which had been conducted in one or two of the departmental experiment stations attracted the notice of one planter in St. Kitts. On the strength of these experiments, he determined to make a trial of cotton-growing on a small scale. The results were promising, and they were watched with interest by the officers of the agricultural department. As the outcome of the preliminary trials, it was decided to attempt the cultivation on an extended scale in St. Kitts and in the neighbouring island of Montserrat. The cotton grew promisingly, but difficulties soon cropped up. It will be interesting to trace some of them as indicating what is necessary in building up a new industry.

In the following account little regard is paid to chronological sequence or to distinguishing between the localities in which the difficulties occurred: it will be understood that there was much overlapping as regards the time and manner in which events took place.

It was speedily seen that very special care would have to be taken to obtain the right kind of seed to produce the most suitable type of cotton, and to ensure the production year by year of seed of the required type. Deterioration of type was recognised in the lots of cotton first grown. In some other countries this deterioration soon led to failure of similar attempts to establish an industry. Consequently efforts were made to procure the best types of seed available, and Sir Daniel Morris, then Imperial Commissioner of Agriculture, visited the Sea Island districts of South Carolina in order to learn all that he could of the methods of cultivation and seed production followed there. During this visit he procured several tons of seed of a fine type of Sea Island cotton, which were distributed throughout the cotton-growing areas of the British West Indies. Concurrently, much attention was given by departmental officers in several colonies to questions pertaining to seed production and the selection of good types. As the outcome, not only was seed deterioration arrested, but several good types of Sea Island cotton have been produced, so that the quality of the cotton grown in these islands has tended to improve instead of to deteriorate.

As a further step in this connection, the study of plant-breeding problems in relation to cotton is being carried on in a scientific manner. This work is of very great complexity, and for its prosecution requires the services of workers highly trained in the modern science of genetics. In order that this may be done effectively, assistance has been given by the Department of Scientific and Industrial Research, and a special worker is now engaged in investigating the intricacies of Sea Island cotton-breeding. Already results of a far-reaching character have been secured, and some of the leading principles connected with the raising of the required types of cotton are being elucidated, so that this work, in combination with that of the workers in the several experiment stations, gives assurance that good types of cotton will be maintained in these islands, that desirable new types may be evolved, and also that, as the requirements of the spinners are known, it will be possible to produce the types of cotton which they desire. The importance of this will be recognised when

it is stated that the Sea Island cotton is the finest cotton now grown and that the West Indian types compare very favourably indeed with those which have been produced elsewhere. Sea Island cotton is produced in only one or two districts; practically these are confined to certain areas in Carolina, Georgia and Florida, in the United States, and the West Indian areas into which the introduction has recently been made. The invasion of the Mexican boll weevil, which has now reached almost all the areas in the Southern United States where Sea Island cotton has been grown, makes the cultivation of this cotton practically impossible there. Present production, therefore, depends mainly on the West Indies, though efforts are being made to grow the crop elsewhere. These facts are of the highest significance to the British fine-spinners who use this type of cotton.

No sooner had Sea Island cotton-growing assumed moderate proportions in the West Indies, than a number of pests and diseases made their appearance. Almost any one of these would have sufficed to kill the infant industry if means had not been found to control it. Not only are these pests and diseases new in the experience of the cultivators, but several are new to science. It was necessary to study them in thorough detail and to devise means of combating them. In all this the various officers of the Agricultural Departments worked energetically in conjunction with the planters.

The nature of the work may be judged to a certain extent from the following account of some of the pests and diseases which have to be dealt with.

Cotton worm (*Alabama argillacea*, Hubn.) appeared in great abundance, completely denuding the fields if uncontrolled, thus threaten ing ruin to the crops. The habits of this insect were studied, together with those of the natural enemies which might be capable of holding it in check, of which there are several, and means of controlling the pest by dusting with arsenical powders were developed. The position now is well understood, both by the officers of the agricultural departments and by the planters, including the peasant cotton-growers, who require, however, much supervision on the part of the departmental agricultural instructors in order to prevent the invasion of the pest and its spread to their neighbours. Several tons of arsenical powders, such as Paris green, London purple, and calcium arsenate, may be required for use in a season when this pest is prevalent.

Much alarm was caused in the early days of the industry by the appearance of a new and hitherto unrecorded pest, which attacked all parts of the cotton plant, except the roots, causing the formation of small galls, or blisters, and the distortion and stunting of the leaves and other green parts. This was shown to be due to the invasions of a microscopic mite, *Eriophyes gossypii*, Banks, an insect new to science, new also to agricultural experience, for which the remedial treatment was not known. The investigation of this pest involved much work and many remedial measures were tried; ultimately it was found that the best means of controlling it is by instituting close seasons during which no cotton plants are permitted to be in existence, all cotton bushes being destroyed prior to the date fixed for the beginning of the season, and no planting being permitted before its expiration. Regulations to this effect are enforced by law in the several islands where cotton-growing is of importance.

Another pest which threatened the industry is the flower-bud maggot, *Contarinia gossypii*, Felt. This is the maggot of a minute fly, or midge, which lays its eggs in the very young flower-bud of the cotton. From the egg develops a small maggot, which causes the blossom to fall off. The attacks of this pest are sometimes so severe that the attacked fields produce practically no cotton at all. This pest, too, was entirely new to science and to agricultural experience. It has not been found possible to devise direct remedies, and the best means of control yet found is the careful destruction of infected material, and the regulation of the planting so as to avoid the later periods when the pest tends to become abundant. This pest still remains somewhat of a menace to the industry.

Red maggot, *Porricondyla gossypii*, Coquillet, the larva of a small fly, attacks the stem of the cotton plant in some localities; the cotton aphis, *Aphis gossypii*, Glover.; the cut worm, *Prodenia*, spp., various scale insects; red spider, *Tetranyphus gloveri*, Banks; the Lachnophus weevil, have all, at various times, caused trouble and anxiety to cotton-growers, and have been the subject of study and investigation on the part of the scientific staff and the field officers of the departments.

In addition to trouble arising from insects attacking the growing plant, there are those which attack the stored seed, and these have had to be dealt with.

Many fungus diseases have proved alarming, and in some cases disastrous, to cotton-growers in the West Indies. Some of these attack the

leaves, as leaf rust, due to *Uredo gossypii*; leaf mildew, caused by an undetermined fungus, and angular leaf spot, due to *Pseudomonas malvacearum*. Other leaf diseases are known which are not parasitic, but which appear to be due to adverse physiological causes; amongst these are the curly-leaf disease, and the so-called loggerhead disease. A red leaf disease symptomatic of potash shortage is at present much in evidence in St. Vincent.

Of great importance are the fungus and bacterial diseases which attack the boll—amongst these are rots caused by Phytophthora and other fungi; a serious rot caused by *Pseudomonas malvacearum*, characterised at the outset by lesions on the outer surface of the boll; but most important of all is the disease known as the internal boll disease. As this disease has given rise to some of the most interesting, complex, and successful work of the Imperial Department of Agriculture, involving the co-operation of other workers in the local departments, it may be dealt with at some little length, for it well illustrates the nature of the work which departments of agriculture are called upon to do when the introduction of new crops is under consideration, and the remarkable complications which ensue.

The internal boll disease of cotton was observed in the early days of cotton cultivation, but its real nature was not ascertained until after some ten years of work, for it presents complications which proved baffling. When the diseased bolls were examined on various occasions, it was first thought that the rotting of the lint was caused by a bacterium; further investigations led to the discovery in other instances of a fungus of a peculiar type; further research showed that at least four related species of fungus are to be met with, and in a few cases bacteria may also be involved. Seeing that no external lesions are visible, the question of the manner in which the disease, whether in its fungus or bacterial form, gains entry to the boll, presented difficulty. From the presence of internal proliferations associated with tiny puncture marks, it was suspected that the plant-sucking bug, *Dysdercus*, known locally as the cotton stainer, might be involved. After long inquiry and careful work, it was finally proved that Dysdercus does convey the infection, so that it was evident that remedial measures must include the elimination of this insect. Here at once further difficulty arose, for no parasite or natural enemy is known to attack Dysdercus to any appreciable extent; few birds will eat it; and it cannot be controlled by placing poisonous materials on the cotton bolls, for it feeds by sucking the juices from the seeds and so avoids the poison. It will readily be appreciated that this situation gave rise to much work and to no little anxiety. Finally, it was agreed that the best methods of attack would be by combining starving the insect with hand-collecting. From the fact that these insects occur in enormous numbers and breed with extraordinary rapidity, hand-collecting would be of little avail unless the process of starving them tended to reduce their numbers. The adoption of the close season already mentioned was looked to to reduce their numbers, but it was soon observed that the insects were carried over in great abundance from one season to another owing to their finding sustenance on other plants. It became necessary, then, to deal with the other food plants, and legislative powers were taken to enable officers of the Agricultural Department to enter upon anyone's land and destroy the food plants of the cotton-stainer. The cotton-growers themselves, in many instances, entered actively into the campaign, and destroyed such food plants on their properties and assisted the agricultural officers in their efforts to destroy them elsewhere. Investigation shows that two trees were principally concerned in the maintenance of the insect in the absence of the cotton plant, namely, *Thespesia populnea*, a malvaceous tree common on the beaches, known locally under the names "John Bull" or Seaside Mahoe, and others, and the second the Silk Cotton, *Eriodendron anfractuosun*. It was no easy task to destroy all these trees throughout an island, or even to reduce their numbers to insignificance, but by vigorous and well-directed activity this task was accomplished in St. Vincent, and is in process of accomplishment in other places. Those who are familiar with the tropics will realise that the destruction of such huge trees as the silk cotton, long famous for its bulk and fantastic shape, presents peculiar difficulties, nor are these difficulties lessened by the fact that these trees are often regarded by a superstitious negro peasantry as the abode of evil spirits, jumbies or duppies, who will wreak vengeance on those who destroy their haunts. Fortunately, it is also a matter of superstition that less harm is likely to happen if the cutting of the tree is done by a left-handed man. Now the Agricultural Superintendent in St. Vincent happened to be ambidextrous, so it was diplomatic for him to begin the work with a few left-handed cuts, when the timorous work-people could continue it, proclaiming under their

breath, "Its no me do it; its Mr. S." In this way the work was carried to such a successful point that the trees were destroyed, practically eradicated, but the superstitions were to some extent supported, for a falling tree killed one of the workmen, thus showing how dangerous it is to meddle with the supernatural.

So successful has been the result that the cotton-stainers are very largely under control in St. Vincent, and on the belated arrival of small swarms are capable of being kept within bounds by hand-collecting. This work has altered the whole aspect of cotton-growing in St. Vincent. The prevalence of internal boll disease not long ago threatened to extinguish the cotton industry there, for in that colony difficulty is experienced in reaping an early yield owing to the prevalence of boll-rotting diseases encouraged by the heavy rains, while the later yield in drier weather was ruined by internal boll disease. From these causes the production of cotton per acre in St. Vincent fell steadily until it had reached a point when the industry ceased to be remunerative at ordinary prices for cotton. Since the adoption of the remedial measures here detailed the yield has been practically doubled, though it is still lower than is desirable, and it is hoped that the ability to combat this major evil will give such encouragement to all concerned that it will now be found possible to deal effectively with other troubles and to bring up the yield of cotton in St. Vincent to a high figure, comparable with that attained in islands less embarrassed by disease and difficult climatic conditions.

It would be possible to extend considerably this list of matters which have required consideration at the hands of departmental officers in connection with the establishment of the cotton industry. Something might be said about the knowledge which had to be obtained concerning the ginning of the cotton, for much of the information that had to be gained was acquired through the aid of the agricultural departments, and in some instances departmental officers had charge of ginneries and their working. Similarly, a good deal of departmental assistance has been given in the marketing of cotton and in formulating the knowledge that has been gained in regard to the various types of cotton and their suitability for the requirements of the spinners. Sufficient, however, has been said to show how considerable and how varied is the departmental work which has been invoked in order to establish this one industry.

The simple outline so far given of some of the work done in recent years may serve to show how different is the outlook of a modern agricultural department in the tropics from that of the botanic garden in which it had its origin, and whose functions amongst many others it still continues to discharge.

It is evident that these changes of function and outlook involve changes in the men who have charge of the several branches of these institutions. For work in the botanic gardens men were required who had botanical knowledge coupled with horticultural skill extending to some knowledge of the economic uses of the plants introduced and recommended for wider propagation. If these workers were skilled in knowledge of how to deal with these plants as crops when grown on a large scale so much the better, but the planter was supposed to take care of this aspect of the case. The process of evolution into the agricultural department, however, soon called for the help and advice of specialist workers whose knowledge in various directions went beyond that of the practical agriculturists; hence it occurred that in the evolutionary process, first chemists were called for to advise concerning soils, fertilisers, and the manipulation of plant products such as sugar, lime juice, cacao, and other products. Then it was soon found that insect pests were threatening most of the crops grown, in some cases to the extent of destroying them, so entomologists were added to the departmental staffs; but this was found to be insufficient, for when insect injuries were investigated it was found that many of the troubles were due, not to insects, but to fungi and bacteria, so recourse had to be had to mycologists.

Hence we find that in most tropical agricultural departments which have evolved in the manner indicated, the scientific staff consists of a chemist, an entomologist, and a mycologist, while the botanic garden, with its associated experiment station, often grown to dimensions which overshadow the botanical aspect, is under the charge of an officer who has had training in botanical knowledge coupled with that pertaining to horticulture verging into agriculture; his assistants are usually men who can carry information regarding the recognised and approved methods of agricultural practice to cultivators, including in this work advising as to the application of methods recently made known, either in regard to particular crops, or the remedial measures to be adopted to control the pests and diseases to which they are liable.

The members of the staff of an agricultural department so equipped must, in order to be of service to the agricultural community, get into touch with agricultural practice proper, so that there is a disposition for the workers added to the departments to endeavour, and rightly, to gain an acquaintance as complete as possible with agricultural practice; and in the final result we have tended to get agriculturists with a chemical, an entomological, or a mycological point of view.

This is where matters appear to stand to-day in most tropical agricultural departments, but the process of evolution does not end here. We are now confronted in the tropics with the necessity for investigating agricultural problems of great complexity concerning which our guides in other countries and our text-books are unable to help us. New knowledge is necessary for the solution of many of the problems on which successful progress in agriculture in the tropics depends. There is need for those who can give us further information concerning the various plants grown, and to be grown, as tropical crops; information concerning the physiology of the plants, their adaptability to their surroundings, both customary and new; information concerning the influence of climate as affecting crops and the limitations exercised thereby, and generally as to the relation of the several plants to their environment—all work of the botanist, plant physiologist, or ecologist, as yet almost unknown in relation to tropical agriculture.

Similarly, many soil problems require investigation in the light of the flood of increasing knowledge relating to soil physics, soil biology, and many cognate matters. These things call for the work of specialists of a class hitherto not considered necessary in the tropical agricultural departments.

Much more remains to be done in connection with plant pests and diseases than the limited number of entomologists and mycologists have been able to undertake, and we may expect substantial addition to their ranks. On the scientific side concerned with investigations and the making of additions to knowledge there is room for much expansion—for many problems, some of immediate practical bearing, are calling for solution—and it is along these lines that we may look for developments in the near future.

On what may be regarded as the more immediately utilitarian side, such as concerns the agricultural superintendents, the curators and those having charge of matters immediately concerned with the production of crops, there has been a great expansion in outlook. This is evident when it is remembered that an agricultural superintendent in one of our smaller colonies is now expected, not only to maintain his botanic garden and his experiment, or demonstration station in good order, so as to afford enlightenment to the agriculturists of the community, but he must be alert to recognise the appearance of disease, troubles, or deficiencies in the staple crops as well as the minor crops of his district. He is looked to to provide, or indicate the manner in which can be obtained the material required for planting various crops and either himself to undertake or to show how there can be undertaken, the best methods of maintaining the most desirable types of the crops that are cultivated locally. He is looked to, to a large extent, as the medium through which the researches and investigations of the scientific officers reach the agriculturists and are applied in practice. He is required to assist actively in such matters of economic interest as the development of those industries which require State assistance, such as the operation of cotton ginneries, corn driers, granaries, lime-juice factories, onion buying and marketing institutions, and other agencies of a semi-commercial or fully commercial character; to give assistance in establishing such organisations as agricultural credit societies, to be active in connection with the local agricultural society, that important medium through which the agricultural department can make known its views and researches to the planters, and by means of which the planters in turn can make known their requirements to the department. All this and much more implies wide knowledge, common sense, and special aptitude on the part of any man who becomes a successful agricultural superintendent.

Thus regarded and equipped in the manner discussed, tropical departments of agriculture are organisations of great complexity, involving in many of their aspects a high degree of specialisation on the part of their workers. This gives rise to two problems—the training of the men to be engaged in the several activities of the departments and the manner in which such departments may be organised and held together.

In regard to the first of these considerations, most of the workers in the West Indian departments have gained the greater part of their tropical training and experience in connection with the Imperial Department of Agriculture

and the several local agricultural departments associated with it. In their several degrees the men engaged have had good sound general training in the subjects more immediately connected with the duties which they have come out to undertake, in so far as this training can be given in institutions outside the tropics. Their tropical training has been acquired in the course of the performance of their duties. Seeing that the several West Indian islands present great diversity in regard to their agriculture and in regard to the problems to which this diversity gives rise, and seeing that by their association into an organised group through the activities of the Imperial Department of Agriculture, there has been brought into close relationship a fairly large body of men of diverse training, knowledge, and outlook, the Imperial Department of Agriculture has proved a good training-ground, and men have gone from it and its associated departments to all parts of the tropical world, where they have successfully undertaken a great variety of duties as workers in botanical and agricultural establishments of various kinds and as scientific investigators and advisers connected with such establishments.

The future, however, calls for something more definite in the way of training than this, for there is a demand for a greater number of men than can be provided in this way, and for men whose work and duty lie beyond the confines of official agricultural departments. Trained men of many and diverse grades are required for plantation work all over the tropical world, so that there is immediate need for the establishment of a Tropical Agricultural College, whereby the present deficiencies in the way of training may be made good, and a supply of trained men be provided. The call of the tropics for development is urgent, but the men capable of intelligently obeying the call are relatively few in number.

A further aspect of an agricultural college is that it would provide a means of extending work in regard to research and abstract investigation. Associated in some manner, as it should be, with an agricultural department, it should help to extend the research work of the department, while in turn receiving inspiration with regard to the real needs of tropical agriculture in its practical aspects.

This brief reference to a tropical agricultural college must suffice: the subject is one which is receiving earnest attention at the moment on the part of responsible authorities, headed by the Secretary of State for the Colonies. It is a subject which will doubtless have consideration on the part of the Royal Society of Arts as one of the many institutions which take an interest in the maintenance and development of our tropical possessions, now recognised as being of such importance to our national welfare.

With regard to the second problem—namely, the manner in which the departments may be organised and held together—something may be learned from the history and working of the Imperial Department of Agriculture.

Where a number of relatively small, scattered communities occur, such as exist in the West Indies, it is essential to have some centralising or grouping organisation, for it is not possible to maintain the full machinery for agricultural administration in each small community; this function the Imperial Department well fills. It presents the advantage that, through the medium of the scientific officers maintained on its staff, it is able to undertake researches and to give advice concerning matters with which local observers and agriculturists are not fully informed, or which, as so frequently occurs, are entirely new to experience, and have to be completely investigated before advice can be given concerning them. As a centralising organisation it is able to assist in ensuring that the agricultural work in each of the scattered communities is maintained on similarly advanced planes and that knowledge gained by experience is rapidly passed from one to the other. Through its agency it has been possible to induce greater uniformity in connection with matters of common interest, notably in such matters as concern the regulations regarding plant pests and diseases and those relating to measures taken for the prevention of the introduction of these into the several islands. Through its operations much has been done to ensure continuity of agricultural policy; it is of material service in advising concerning the staffing of the several departments and in aiding the selection of suitable officers and their transfer to advantage when vacancies occur, and in many matters of administrative detail.

An important function is the assistance it is able to afford in framing the agricultural policy of the communities, directing attention to desirable, or necessary, lines of work, supervising the work when in progress, and often preventing retrogression under the influence of narrow or mistaken lines of policy, agricultural as well as administrative.

These and similar functions are capable of

being exercised when advice is sought in regard to the larger colonies, and in this connection it is felt that there is scope for extended usefulness.

It has been the purpose of these remarks to indicate in some degree the manner in which the several West Indian agricultural departments have been evolved from the simple gardens intended to foster plant introductions; it will be recognised that in this progress great complexity has arisen, rendering desirable the existence of centralising institutions, failing which it would be difficult, or impossible to maintain the progress already instituted. The impetus gained may enable the work to be maintained for a time, but the momentum would diminish, and first the smaller communities and then the larger would fall back into a condition of isolation and stagnation in which they would be unable to maintain themselves in face of the economic struggle and competition which must inevitably soon make their pressure acutely felt once more. Closer grouping, improved means of agricultural education, and increasing agricultural research are all called for in greater degrees in the future. The work instituted by Mr. Joseph Chamberlain some twenty years ago with a view to relieving the necessities of the West Indies has borne good fruit, and its continuance should be assured by the formulation of well-thought-out plans for the future.

[The paper was read by Captain Arthur W. Hill, M.A., Sc.D., F.L.S.]

DISCUSSION.

The Chairman (Sir David Prain), in opening the discussion, said the Society was indebted to the author for an exceedingly luminous history of the recent progress in West Indian agriculture, while it was perhaps more indebted to him for having given an account of the stewardship of the Imperial Department over which he presided. In both those respects the paper was intensely interesting to all West Indians, past and present. With reference to the account the author had given of how it had become necessary in certain colonies for agricultural departments to take the place of the older botanical departments, in small colonies the question of cost came in; it was not possible to afford two departments of the kind. One had to be considered as a luxury which must be dispensed with, and as a result the botanical departments had suffered. Only in the larger dependencies, such as India, was it possible to continue the existence of both departments. There was a considerable disadvantage in the loss of a botanical department. An agricultural department did excellent work in instructing the producer of crops, but, unfortunately, in all countries in which agricultural interests were the principal concern it was necessary for the Administrator to know something not only about the crops but about those natural vegetable products which were the sources of revenue of the colony or dependency which he had to administer. An agricultural department could instruct the grower, but it was not always quite so easy, and it needed a botanical department, to educate the Administrator.

Sir George R. Le Hunte, G.C.M.G., late Governor of Trinidad and Tobago, desired to bear testimony to the undiluted success of the work which had been done by the Imperial Department of Agriculture in the West Indies. It might be summed up by saying that Kew had been brought to the islands instead of the islands going to Kew. He was very glad to meet Captain Hill again. He represented Kew at the West Indian Agricultural Conference in Trinidad when he (the speaker) was there. The detailed account given in the paper of the many tropical plant diseases which had to be dealt with reminded him of the remark of a friend of his that gambling on the Stock Exchange was a solid security compared to embarking on tropical agriculture. But although agriculturists had a great many troubles to face, they now had the means of circumventing and combating them, and one of the greatest helps that the tropical planter had ever possessed was the agricultural departments in the West Indies. Most of them were the children of Kew and the Board of Agriculture. Such a department existed in Trinidad, and they were always delighted in that Colony to welcome the Director or any of the officers of the Imperial Department of Agriculture. He remembered that when the Department was started he was in Dominica, and an arid-looking part of a sugar estate was then purchased and had now been turned into one of the most beautiful tropical gardens in the world. He recollected a planter friend of his in Dominica sending a box of leaves from a lime tree to the Agricultural Bureau in America asking for advice in the treatment of a disease which affected the leaves, and he subsequently received a reply requesting that in future the leaves from separate trees should be sent in separate parcels, because thirteen different diseases had been discovered in the leaves which he had sent. As a matter of fact, they came from only one tree. When a planter was faced with such difficulties it was necessary for him to turn to some doctor to help him, and he now possessed the advantage of being able to consult the officers of the Imperial Department of Agriculture. Reference was made in the paper to the establishment of an agricultural college in the West Indies, and he trusted that if a discussion took place at any future time before the Society on that question he would be invited to attend, because he foresaw a rather big war between the interested parties, and he would be very anxious to see which way the battle went.

MR. A. HOWARD, C.I.E., M.A., F.L.S., Imperial Economic Botanist to the Government of India, said he desired in the first place to discuss the question of the best method of procedure on the part of scientists who went out to the tropics to advance agriculture. It had been found in India that a very successful method was for the scientists to take up the subject, so that they combined in one person a practical experience of agriculture and of a particular science. There were now a large number of experimental stations in India, in which all the details were managed by the scientific men in addition to carrying out their own particular work. A large portion of the paper was taken up with references to diseases of various crops, and in that respect a good deal of new ground had been broken in India in the last two or three years. The orthodox view was that the diseases were caused either by insects or by fungi, and that the best method of attack was to study the life history of the insects or fungi and to endeavour to find some remedial method of control. The subject was now being looked at in India from a somewhat different point of view. It had been found that insects and fungi, although important factors in the case, were not everything, and results in the treatment of disease were now being obtained by considering the physiological activities of plants, particularly the distribution of the root system and the effect of the physical texture of the soil. During the last two or three years it had been found possible to grow cotton in parts of India with a rainfall of 70 inches absolutely free from disease, a thing that was considered impossible in days gone by. That had been brought about by selecting soils in which the physical texture was practically perfect and in which healthy root development was possible; and a large number of similar results were now being obtained at other centres. The treatment of disease now appeared to be very much more hopeful. It was not a question so much of spraying as of improving the physical texture of the soil, and selecting types of plants with root systems which were specially adapted to particular classes of soil.

MR. C. SANDBACH PARKER, C.B.E., said that as one long interested in sugar-growing in British Guiana he desired to add his personal testimony to the value of the Imperial Department of Agriculture in the West Indies. British Guiana, like Trinidad, had its own department, and in addition there were individuals who were doing pioneer work; in fact, British Guiana in that respect was rather more modern than some of the West Indies, but he thought there was not the slightest doubt that the more the Imperial Department of Agriculture was used the more valuable it would be to tropical agriculture, not only in the West Indies, but in British Guiana and other tropical countries. It was only necessary to refer to the wonderful statistics which were compiled by the Department of Agriculture of America and her colonies in connection with the growth of sugar to find out what could be done by the co-ordination and extension of their efforts in that direction in the West Indies and British Guiana. Unfortunately, during many years past the interests of the West Indies were left very much to West Indians themselves, except for the help of Mr. Chamberlain, but changed ideas were now apparent in the Imperial Government, and there was a desire to develop the agricultural industries of all the tropical possessions of the Empire. He hoped that had come to stay, and if it did so there was an era of prosperity in front of the agricultural industries of the British possessions in the tropics such as they had never experienced before.

MR. A. ABBOTT said the Department of Scientific and Industrial Research, with which he was connected, was engaged in the task of establishing a number of research associations. Each of the associations consisted of a group of British manufacturers who, feeling that they had common interests, had embarked on a scheme of co-operative research. About nineteen of those associations had so far been approved, of which six or eight were at work. It became obvious at a very early stage that if those associations existing in England began their work of research on the raw materials as they entered these shores, they would be too late; it was necessary to make an earlier start and to carry on research as to the method of production of the raw materials. It was evident that it was impossible to improve the quantity of mineral productions very largely—at any rate, it could not be improved indefinitely; the number of animal products was not large, but the number of vegetable products grown in tropical countries filled an extremely long list, including timber, flax, cotton, jute, cocoa, rubber, oils, seeds, spices, drugs and certain dyes; and that pointed to the necessity of carrying on research on a large scale. He did not know the exact means that should be devised for the purpose, but it was necessary that they should be considered. Looking at it from the point of view of the man on this side who knew nothing of the West Indies, there were several directions in which help could be accorded. First of all it was possible to communicate to the tropical departments abroad the results of research carried on in this country in pure science at the universities. Secondly, it was very desirable that the producer abroad should be in very close contact with the user or the manufacturer on this side. That was one of the factors which had not been developed as much as it might have been in the past. The user in this country ought to be able to tell the producer just what he wanted and why he wanted it, and the producer in the tropical country must have some knowledge of what the user in this country really needed. Thirdly, tropical countries must depend on this country in the main for their supply of technical men. Until quite recently, if a manufacturer

wished to have a scientific man in his works he selected a chemist as being the one scientific man who could help him. It was just beginning to be recognised that the physicist as well as the chemist could do extraordinarily useful work in industry. It had scarcely been recognised, in this country at any rate, that the botanist and the entomologist had a very wide industrial field for their work; but it was quite impossible for the country to secure an adequate supply of men of that type unless it could be shown that a career awaited them in industry. As soon as the possibility of a career was obvious to young men, they would follow their bent and take up that particular line of work.

Mr. G. Moody Stuart said the paper contained a record of twenty-one years' unobtrusive work, which was hardly known except to those who were personally connected with it. As he happened to be in that position, he desired to take the opportunity of saying that he firmly believed the Agricultural Department had been of untold value to the West Indies. The Sea Island cotton industry was not only made but saved by the Agricultural Department in the West Indies, and many estates and several islands had been brought out of very uncomfortable uphill conditions into a position of comfortable well-being by the development which had taken place, a development entirely due to the work of the Department. Not a particle of what had been done in sugar development in Antigua would have been done except for the Department. The factory there had now completed fifteen years' work, and during that time it had saved sugar to the value of £430,000 which would otherwise have been wasted. That was not a bad single item to the credit of the Department. The greater part of that money had gone to the planters, and through them a fair portion had filtered to the estate managers, overseers, and labour. The author had referred to the necessity of the Department being maintained from Imperial funds, because that had been the main element of its success in the past. Personally he strongly supported the suggestion, because he felt sure that if a change were made it would be a very dangerous thing for the Department. It might be said that the West Indies ought to be able to bear their own burdens, but as a matter of fact they were bearing them to the full now. The sum of £130,000 had been given as a grant-in-aid, in addition to which the Mother Country had also borne the cost of the headquarters, but she had received much more than that back again in excess profits and income tax, which would never have been paid but for the work of the Department. A large proportion of the estates and many of the factories were owned in England, and on the profits that were made the Treasury received income tax, so that the Imperial Treasury would be looking only at one side of the account if they looked at the expenditure only. The success of the Department was due to the chemists and the men who had come from Kew, but he ventured to suggest that when the next vacancy occurred a practical agriculturist with scientific knowledge should be appointed, one well acquainted with practical farming, drainage and manures. The chemists had trusted to the planters themselves being well up in the best methods of agriculture, but as a matter of fact they were only employing methods which were known to their forefathers. Agriculture had taken such big strides in recent years that he was sure that if a man who was thoroughly well up in practical farming was appointed it would be to the benefit of the colonies. He desired to refer, in conclusion, to the spirit in which the Department had been run from first to last. It was not a typical Government Department. Usually in approaching a Government Department one felt that one was going to an authority which might or might not condescend to be interested in one's case; but in going to the Agricultural Department one always felt that one was asking for professional advice in the same way that a client went to a lawyer or a patient to a doctor, and that one was given the advice as willingly and readily as any professional man gave advice to his client.

Dr. Louis W. Sambon said that, having had the privilege and pleasure of visiting the Lesser Antilles in the instructive company of Sir Francis Watts, he eagerly seized the opportunity of expressing his high regard for the writer of the paper and his admiration for the work he had carried out in the West Indies. While travelling with Sir Francis, who was on a tour of inspection, he could not help wishing that the medical and sanitary work were conducted on lines such as were being followed by the Imperial Department of Agriculture. As a student of ecology in a different field, he desired to emphasise the importance of a college such as had been outlined by the author, because no doubt the teaching of the principles of ecology would enable them to obtain men capable of raising good crops and of controlling the pests and diseases of plants. The ancients had achieved wonders in agriculture. Had time permitted he would have liked to remind them of the terraced agriculture of the ancient Mexicans, of the hanging gardens of Babylon, of the Roman transportable forcing-houses, of the controlling of crop-pests by their natural enemies. An Assyrian clay cylinder, 2,500 years old, in the British Museum, handed us down Sennacherib's boast that cotton-trees throve better in his gardens on the Euphrates than in their native land. At that time, whilst Hindu, Hellenic, and Egyptian girls danced in transparent muslins—true "webs of woven wind," as they were called in Sanskrit literature—the ancient Peruvians swaddled their dead in cotton bands. Moderns should at least equal, if not surpass, their endeavours, and thus be worthy followers of the ancients, whose inheritance they were so fully enjoying.

DR. C. A. BARBER, C.I.E., F.L.S., said he had the greatest possible sympathy with the suggested agricultural college, because he felt that tropical agriculture was entering upon a new intensive phase which was not only directly but indirectly caused by the late war. There was a vast need for raw products, which were being produced in immense quantities, but nevertheless they could not be obtained in manufacturing countries. As a result there was an increasing tendency to deal with those raw products on the spot, an increase in the number of the factories in the tropics thereby being brought about. A large increase was taking place in the departments of agriculture all over the tropical world, and many new men were required from this country to carry on that work and extend it. It was necessary with regard to diseases to study the actual growth of plants more carefully, and not to be content with simply naming the disease, the fungus or the pest, without attempting to ascertain why it was caused and without endeavouring to provide a remedy for it. He very much doubted whether a single agricultural college would be sufficient for the West Indies. In India there were a series of regular agricultural colleges, but none in the colonies. They were needed in the West Indies, and soon would be in West Africa, the Transvaal and Natal, Uganda and British East Africa, Mauritius, Ceylon, Queensland, and Oceania. If men for those colleges were to be supplied, it was necessary to do more work in England, and in that respect he did not think the present method of obtaining men for the tropical agricultural departments was likely to succeed unless some scheme of co-ordination between the new agricultural colleges and those in this country was put into force—some scheme of preliminary training to bridge over the gulf between the knowledge of agriculture in temperate climates and in the tropics. From long experience of the tropics, he found that it took sometimes two or three years before a man who had been trained in an English college was in a position to adapt himself to his surroundings and to be of much use.

SIR EVERARD IM THURN, K.C.M.G., K.B.E., C.B., in proposing a hearty vote of thanks to Sir Francis Watts for writing the paper, and to Captain Hill for reading it, and at the same time informally thanking Sir David Prain for his kindness in presiding over the meeting, said that he saw, perhaps more than anybody else present, the beginning of the operations which Sir Francis Watts had described. Forty years ago he was resident in British Guiana, before the Botanical Gardens there existed. He saw the extraordinarily good work which the first Curator, the late Mr. G. S. Jenman, did, and the subsequent work performed by his successor, Dr. Harrison. The contrast between the botanical garden work and the agricultural side of the work had been in his mind during the reading of the paper. He quite saw the necessity for practical purposes that the agricultural tendency should take the lead, but at the same time he could not help feeling a certain amount of regret at the dropping of the botanical garden side of the question. Speaking from his own long experience, he was perfectly certain that the care which was given to the introduction of minor products and not merely the main products, be they sugar-cane or coconuts, should be a very important feature of any agricultural department; and though attention must be paid to commercial products, he hoped the smaller and minor industries would not be overlooked. He did not mean for a moment to suggest that they were purposely neglected, but there was a strong suspicion that they were being allowed to drop out. A good deal had been said in reference to the advantages of a large Agricultural Department formed by the union of various smaller institutions, and he would like to see that principle extended still further. In any Imperial Agricultural Department the outlying parts of the world, which had practically been untouched from the scientific agricultural point of view, had not yet been taken much into consideration. In that connection he desired to utter a note of warning, that the conditions of agriculture in the Pacific and in the West Indies were so extraordinarily different that when men were being trained for agriculture in the West Indies it was necessary to bear in mind that, if they were transferred by any chance to Oceania, the conditions there would be very different. For instance, the conditions under which sugar-cane was grown in Fiji and in the West Indies and British Guiana were extraordinarily different.

SIR LOUIS DANE, G.C.I.E., C.S.I., in seconding the motion, said he was very glad to find that an attempt was being made to overcome the difficulties that at present existed in regard to the importation of Indian labour into the West Indies. The West Indies depended to a very large extent upon India for their labour, and he hoped therefore that the present difficulties would be surmounted. He thought, however, it would be wise for the administrators of the West Indies to realise that it would be quite impossible for them to secure Indian labour in the future upon the old terms. He had no doubt whatever that Indian labourers would be forthcoming, but it would be necessary for the West Indies to take them absolutely as free labourers, and if they did so plenty of excellent labour would be available. Speaking as an Indian Administrator, he was able to say that he had never heard of any trouble at all with the returned immigrants from the West Indies or British Guiana, who were peaceful and prosperous men, although trouble had been experienced when Indians had returned from other parts of the world. He agreed with Sir Everard im Thurn that it was absolutely necessary to have not only an agricultural department and colleges, but also a botanical department and botanical gardens. The two really did not serve the same purpose. The first dealt with commercial agriculture; the

second dealt with the introduction of new specimens which were to a great extent entirely beyond the scope of the economic botanist employed in the Agricultural Department. The West Indies as a field for agriculture was practically a new one, but in India the circumstances were entirely different. India possessed the accumulated experience of centuries of agriculture, which was often crystallised into the very wise saws of the peasantry, which embodied great truths. The agricultural experts who went out to India from this country had at first a tendency to regard the natives as absolutely wanting in all knowledge of correct agriculture. There never was a greater mistake. Every year it was being found that Indian practice was based upon sound agricultural principles, although the people who practised them did not know the why and wherefore for them. He was glad to say the agricultural experts were beginning to find that it was necessary to do what was suggested in the paper, namely, study the local conditions and associate themselves very closely with local agriculturists of experience, and most happy results were hereby being produced. He could not help thinking that if there was a closer union between the Imperial Agricultural Department of the West Indies and the Agricultural Department in India they would be able to benefit each other very largely. A great many of the difficulties, especially those affecting cotton and sugar-cane, that were experienced in the West Indies also obtained in India; in fact, the same problems cropped up in all the various dependencies, and it was therefore essential that there should be free communication between them, and also a certain amount of personal visitation.

The resolution of thanks was put and carried unanimously.

Captain Hill, after acknowledging on behalf of Sir Francis Watts and himself the vote of thanks, said it was only possible for him in the short time at his disposal to refer very briefly to the remarks made by Mr. Howard. The Mycologist of the Imperial Department of Agriculture, when visiting Trinidad, found that the trouble experienced by the planters with regard to the frog-hopper on the sugar-cane was not so much linked up with insects or fungi as with the physiological conditions under which the plants were growing, and by taking steps to remedy the deficiencies in the cultivation the pest had been largely brought under control.

Sir Charles Lucas, K.C.B., K.C.M.G., in expressing regret at his inability to attend the meeting, writes: I should have been glad to have been there to bear witness to the Imperial Department of Agriculture in the West Indies, to the splendid support given to it by the Directors of Kew Gardens, from which it gained Sir Daniel Morris, and to the very able services of the writer of the paper, Sir Francis Watts. It is not too much to say that the present regeneration of the West Indies from the decay into which they had fallen towards the end of the last century has been very largely due to the work of the Department of Agriculture.

Sir Daniel Morris, K.C.M.G., D.Sc., F.L.S., who was also prevented from being present, and to whom an advance copy of the paper was sent, writes: It contains a remarkably full and careful account of the evolution of agricultural efforts under the fostering care of the Imperial Department of Agriculture, and brings out very forcibly the value of scientific research in promoting the welfare of our tropical possessions. It is quite in keeping with the traditions of the Royal Society of Arts that this paper should be read under its auspices, as more than 150 years ago it presented its gold medal to Dr. Young, then head of the Botanic Garden at St. Vincent, in recognition of the flourishing state of that institution. A great deal has been accomplished in the West Indies since those days. Among some of the results of enlightenment in regard to agricultural matters, it has been shown that the public revenue of the colonies before the war had increased from two and a half million sterling to nearly four million; while the total trade had increased in value from seventeen million to nearly twenty-seven million sterling. In the case of the comparatively new cotton industry, which owes its existence so largely to the efforts of the Imperial Department of Agriculture, the exports in recent years have reached a total value of nearly two million sterling. Sir Francis Watts has rightly drawn attention to the fact that while the Imperial Department of Agriculture has continuously trained a large staff for experimental work in the West Indies, it has also turned out capable men, of university standing, who now occupy responsible positions in other portions of the tropics. Further, it has been successful in winning wide appreciation of improved methods of cultivation and the value of science among members of the planting community, with the result that the provision for the maintenance of well-equipped staffs, laboratories, and botanic and experiment stations, voted by the local legislatures, has increased from £14,000 to more than £60,000 per annum. Having been so closely interested and taken so active a part in the development of the West Indian Colonies for a period of nearly forty years, I may be permitted to place on record that I am fully convinced of the necessity of the continuance of the valuable work that is being done by the Imperial Department of Agriculture, and I hope that the proposal to establish a central agricultural college for training capable men to assist in the further development of the West Indies will meet with the success it deserves. Sir Francis Watts has very modestly said very little of his own share in the great work that has been accomplished in the West Indies. He was my most valued colleague for many years in the work of the Imperial Department of Agriculture, and the great success of his efforts in connection with the

establishment of central sugar factories at Antigua and St. Kitts, and indirectly also at Jamaica and Barbados, will always be most closely and gratefully associated with his name.

SUGGESTED DEVELOPMENT OF THE EUCALYPTUS INDUSTRY IN AUSTRALIA.

The development of the eucalyptus industry as a way of employing returned soldiers is being urged in Australia, writes the United States Trade Commissioner at Melbourne. There are scores of different kinds of eucalyptus trees, but only a limited number (about six) are of any commercial value. The two most important varieties are the peppermint and the mallee. Good results can be obtained by men working in a small way with either of these species, but anything attempted so far in a large way has not met with much success for many reasons, chiefly because of the difficulty and expense of obtaining large areas of land. With the two species mentioned large areas are necessary because the trees only grow in patches. Thus a distiller who holds a lease of 1,000 acres of land may only have 100 acres that are of any good to him. The mallee gives the best and most valuable oil for medicinal purposes. No mallee, however, can be very profitably worked, according to a practical distiller, unless the scrub has been first rolled down and burned. Suckers spring up very quickly after burning, and it is from these that the distiller gets his profit. Thus in a small way distillers do very well at Wyalong, where large areas have been rolled down by farmers for wheat-growing; but the land is mostly private property there, and unreasonably high rentals are charged for lands worthless for any other purpose. The mallee is being rapidly exterminated for wheat-growing purposes where the soil is at all good. Firewood is scarce for the same reason, and cartage is becoming more expensive as the cutters go farther afield. None of these disabilities, it appears, would exist in a large belt of mallee in Riverina, but private distillers would not take it up because there is no water available and the mallee would need to be rolled down and burned. There is profitable and permanent work in this big belt of mallee for a large number of men, says one distiller, a fact which it is suggested the repatriation authorities might well take into consideration. There they could settle a large number of men and bring into profitable use thousands of acres of Crown lands at present considered absolutely worthless because of the eucalyptus scrub which grows in such profusion. The cost, it is said, would be far less *per capita* than any other means of repatriation so far proposed.

THE KAURI FORESTS OF NEW ZEALAND.

The Department of Lands and Survey, New Zealand, have issued as a pamphlet the report drawn up by Mr. D. E. Hutchins for the New Zealand Government on the Waipoua Kauri Forest, the most important of all the remaining forests of this tree. It lies to the north-west of Auckland, in a somewhat inaccessible area near the Waimaku River, and covers an area of about eleven miles by nine, in a region of heavy mean rainfall, the annual average being well over a hundred inches. The soils within the forest area are poor, the dampness renders the country useless for fruit, and not good for sheep, while the poorness of the pasture makes the keeping of dairy cattle unprofitable. It is estimated, indeed, that it takes five acres to feed one cow. The forest at present is not in good condition, but Mr. Hutchins thinks that it may be restored, and that the process of reconstruction is the most profitable way of using the land.

At present the stand of timber is low and uneven. In places there may be only one kauri tree in ten acres, while the maximum stand is fifty to sixty per acre. The cubic content of timber in the individual trees may, however, be very high, and this is especially true when the kauri stand is thin, and the trees are scattered among other species. In nearly pure stands the trees never appear to grow to great dimensions. On the other hand, Mr. Hutchins maintains that individual kauri trees have reached a greater size than any other tree, exceeding even the Californian sequoias. He mentions two examples in an area close to the Waipoua Forest, each of which contained 295,788 feet of sawable timber, about double the amount of the largest of the Californian big trees known, and equivalent to the production of nearly three acres of good European forest.

As regards natural regeneration, Mr. Hutchins states that though there is little evidence of this in the interior of the Waipoua Forest, it does occur upon its margins. The seed has apparently the power of lying dormant for many years, and only germinates when the conditions are favourable, especially when light is admitted. In other words, it would appear that, in harmony with the slow growth and longevity of the tree, reproduction is slow, and occurs naturally for the most part only when forest fires or destruction by wind make a break in which seedlings may spring up.

Proposals are made for working the forest and for improvements which, it is calculated, would during a period of a hundred years give the same average amount of employment and money returns as successful dairying in this region. At the close of this period the reconstructed forest would give far higher profits and much more employment than dairying.

ONTARIO LINEN INDUSTRY.

With the installation of modern wet-spinning machinery completed, a Guelph (Ontario) company is now turning out wet-spun linen yarns from flax grown in the province. This company is the only one in Canada making wet-spun linen yarn, which is the basic material of the finer linen

fabrics. The mill has a potential output, it is stated, of 750,000 lb. of tow (linen) yarns, and 150,000 lb. of linen (line) yarns per annum. The company expect to receive the maximum amount from the Government bounty of $25,000 a year, which has been offered on linen yarns spun in Canada from Canadian flax.

A flax spinning mill, operating in conjunction with the linen mill, makes this industry a self-contained one, able to turn out linen fabrics, including the finer grades, from raw flax to finished goods. During the war the plant was running on cotton and union goods, because of the difficulty of getting linen yarn; but with a steady supply of Canadian spun-linen yarns now assured, it is turning out all the finer linen goods as well as the coarser grades.

The development of flax-spinning, writes the United States Consul at Kingston (Ontario), will have a stimulating effect on the growing of flax by Ontario farmers. Ontario flax has in the past been found acceptable by Irish manufacturers in the production of the famous Irish linens. A newly invented Canadian machine to harvest the flax which, for purposes of spinning, must be pulled, not cut, is expected to reduce labour costs greatly, and there seems no reason why flax production and spinning, with the complementary industry of linen weaving, should not become one of Canada's important industries.

OBITUARY.

Henry Gribble Turner.—Mr. Henry Gribble Turner, who died in Cairo on February 15th, had been a member of the Society since 1883. He entered the Indian Civil Service in 1864, and was posted to Madras. Here he quickly won the confidence of the primitive tribes inhabiting the Eastern Ghats of the Vizagapatam district, of which he was collector and agent to the Governor at the time of his retirement in 1889.

After he had left the service Mr. Turner devoted himself to the economic development of India. He was mainly instrumental in shipping from India the first ton of manganese, the annual export of which now amounts to 600,000 tons. He was also the pioneer of the export of Indian magnesite, which is of high quality and proved most useful during the war. Another project initiated by him is a great harbour at Vizagapatam to serve the uplands of Central India—a project which is at last about to be begun; while the great and flourishing planting estates of Travancore owe both their conception and inception to him.

Albert E. Reed.—Mr. Albert E. Reed died at his residence at Woking on February 21st. He was born in Devonshire, and established his reputation as a papermaker in the West of England, founding, in 1895, the firm now known as Messrs. Albert E. Reed & Co., Ltd., of Cannon Street, E.C., with mills at Tovil, Maidstone, Horton Kirby, Dartford, and Farncombe. He was one of the pioneers in the use of wood pulp for papermaking, and established a large pulp industry in Newfoundland. During the war he served as a member of the Royal Commission on Paper. In 1906 he contested the Wandsworth Division as a Liberal, and was only defeated by a narrow majority.

He had been a member of the Royal Society of Arts since 1887.

GENERAL NOTES.

Reorganisation of the Board of Trade.—Particulars regarding the reorganisation of the Board of Trade, which has been proceeding since June last, are officially announced. The duties of the Department have been arranged under two Joint Permanent Secretaries, Sir Sydney Chapman, K.C.B., who deals with all questions affecting General Policy, and Mr. H. A. Payne, C.B., who has charge of Administration and Finance. There are eight principal Permanent Departments: (1) Marine, (2) Commercial Relations and Treaties, (3) Industries and Manufactures, (4) Industrial Property (including Patent Office), (5) Power, Transport and Economic, (6) Bankruptcy, (7) Companies, (8) Statistics. There are also a number of sub-departments, including some of which are temporary and are concerned with such matters as the Profiteering Act, Meat Supplies and Enemy Debts. There are also two large Departments which hold somewhat special relationship to the Board of Trade, viz., the Department of Overseas Trade (Development of Intelligence) and the Coal Mines Department. The internal Administrative Council, which has been established and meets frequently to deal with current business involving questions of policy, is presided over by the President. The other members are Sir H. Llewellyn Smith, Economic Advisor to the Government; Mr. W. C. Bridgeman, M.P., Parliamentary Secretary to the Board of Trade; Sir Hamar Greenwood, M.P., additional Parliamentary Secretary to the Board of Trade; Sir Sydney Chapman; Mr. H. A. Payne; Mr. Ashley, Assistant Secretary in charge of the Industries and Manufactures Department; Sir W. H. Clark, Comptroller-General of the Department of Overseas Trade; Mr. Fountain, Assistant Secretary in Charge of the Commercial Relations and Treaties Department; Mr. Hipwood, Assistant Secretary in charge of the Marine Department. Various other officials attend meetings when subjects specially concerning their respective departments are under consideration.

Light and Heat from Gas.—Professor W. Bone, Sir Robert Hadfield, Mr. W. H. Patchell, and Mr. H. James Yates, as a deputation from the Fuel Economy Committee of the British Association, waited upon the President of the Board of

Trade on February 2nd to place before him certain considerations which, in their view, should receive full weight in legislation regulating the supply of gas. Professor Bone said they agreed that the basis of charge to the consumer should be the actual number of thermal units supplied to him. They would, however, substitute in the Fuel Research Board's recent proposal the words "ascertained net calorific value" of the gas for the words "declared gross calorific value." What mattered to the consumer was the actual heating effect he received from the gas as ascertained by independent tests. The Board, which had originally recommended a pressure of not less than two inches of water at the exit of the consumer's meter, had since reduced its proposal to a pressure of not less than two inches of water in any main or service pipe of two inches diameter. The interesting point for the consumer was the adequacy of the pressure in his own pipes and not the pressure outside in the gas mains. It was also of great importance that as constant a pressure as possible should be maintained. The Committee were also of opinion that gas undertakings should be compelled to pay great attention to the removal from gas of the highly poisonous cyanogen compounds. His remarks were illustrated by diagrams taken from experiments. The conclusion of the Committee, he pointed out, was that the proportion of methane (non-poisonous) in coal-gas should not be less than 20 per cent. and the permitted proportion of carbonic oxide (highly poisonous) not more than 20 per cent. Mr. Yates said that in the view of the Committee the minimum number of thermal units should be not less than 450 B.Th.U. net. If gas undertakings supplied gas of lower heat efficiency a large part of the existing gas appliances would become useless. Sir Auckland Geddes promised to give full consideration to the opinions and facts which had been submitted to him.

Demand for Silk Hats.—Notwithstanding the high price now charged for a silk hat—two guineas for a medium quality is a very modest price nowadays—a Stockport correspondent of the "*Times*" *Trade Supplement* reports that the factories both there and at Denton have orders on hand to keep the operatives busy for at least six or nine months. There seems little chance of hatters returning to the longer working day, as was recently urged by the Manchester Chamber of Commerce. There has been another increase in the cost of the high-class silk plush, which is almost exclusively of French manufacture, and according to the same correspondent the price of silk hats is bound to rise before long, it is suggested to the extent of 8*s.* to 10*s.* a hat. The additional advance in the price of the chief material used in the making of silks is attributed to the requirements of the United States, whose merchants are outbidding our own, and sending up the prices by leaps and bounds. The high cost of shellac is mentioned as a contributory cause.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday afternoons, at 4.30 p.m. :—

March 3.—William James Garnett, First Secretary, H.B.M. Diplomatic Service, "Mongolia from the Commercial Point of View." Brigadier-General Sir Percy Molesworth Sykes, K.C.I.E., C.B., C.M.G., will preside.

March 10.—H. M. Thornton, "Gas in relation to Industrial Production and National Economy." Sir Robert A. Hadfield, Bt., D.Sc., F.R.S., will preside.

March 17.—William Worby Beaumont, M.Inst.C.E., "Street Passenger Transport of London."

March 24.—L. Gaster, "Industrial Lighting in its relation to Efficiency."

April 14.—Joseph Thorp, "The Fundamental Basis of Good Printing."

April 21.—Air-Commodore Edward Maitland, C.M.G., D.S.O., A.F.C., "The Commercial Future of Airships."

April 28.—Charles H. Sherrill, "Stained Glass."

May 5.—Dr. C. E. Kenneth Mees, "A Photographic Research Laboratory." Sir Henry Trueman Wood, Chairman of the Council, will preside.

Indian Section.

Friday afternoon, at 4.30 p.m. :—

March 19.—Sir William S. Meyer, G.C.I.E., K.C.S.I., Financial Member of Council of the Governor-General of India, 1913-18, "The Indian Currency System and its Developments." The Right Hon. Lord Chalmers, G.C.B., LL.D., will preside.

Thursday afternoons, at 4.30 p.m. :—

April 15.—Brigadier-General Lord Montagu of Beaulieu, C.S.I., "Roads and Transport in India."

May 20.—Sir George Cunningham Buchanan, K.C.I.E., M.Inst.C.E., "The Ports of India: their Administration and Development."

Date to be hereafter announced :—

Sir Valentine Chirol, "The Enduring Power of Hinduism." (Sir George Birdwood Memorial Lecture.)

Colonial Section.

Tuesday afternoons, at 4.30 p.m. :—

March 2.—G. F. Scott Elliot, M.A., B.Sc., F.R.G.S., "Trade Routes for the Empire in Africa." Colonel Sir Thomas H. Holdich, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., will preside.

May 4.—Professor William A. Bone, D.Sc., Ph.D., F.R.S., "Lignite."

INDIAN AND COLONIAL SECTIONS.
(Joint Meeting.)

Date to be hereafter announced :—

PROFESSOR SIR JOHN CADMAN, K.C.M.G., D.Sc., F.G.S., M.Inst.C.E., "The Oil Resources of the British Empire."

Dates to be hereafter announced :—

GRAILY HEWITT, "Rolls of Honour."

CHARLES CROWTHER, "The Arts and Crafts of Japan" (with examples from the author's private collection).

WILLIAM CRAMP, D.Sc., M.I.E.E., "Pneumatic Conveying Plants, with special reference to the Transport of Grain."

CANTOR LECTURES.

Monday evenings, at 8 p.m. :—

CHARLES FREDERICK CROSS, B.Sc., F.R.S., F.C.S., "Recent Research in Cellulose Industry." Three Lectures.

Syllabus.

LECTURE III.—MARCH 1.—*Cellulose and Derivatives.* Nitrates—Acetates—Progress of research and industry—Specific volumes of cellulose and hydrates—Data of fundamental importance, scientific and industrial—The problems of constitution.

WALTER ROSENHAIN, B.A., D.Sc., F.R.S., Superintendent, Department of Metallurgy and Metallurgical Chemistry, National Physical Laboratory, "Aluminium and its Alloys." Three Lectures.

April 12, 19, 26.

ARTHUR THOMAS BOLTON, F.R.I.B.A., F.S.A., Curator, Soane Museum, "The Decoration and Architecture of Robert Adam and Sir John Soane, 1758–1837." Three Lectures.

May 3, 10, 17.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MARCH 1...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. C. F. Cross, "Recent Researches in the Cellulose Industry." (Lecture III.)

Victoria Institute, Central Hall, Westminster, S.W., 4.30 p.m. Rev. Professor A. S. Geden, "Metaphor and Simile in the Fourth Gospel."

Farmers' Club, at the Surveyors' Institution, 12, Great George-street, S.W., 4 p.m. Mr. A. Amos, "Silos and Ensilage."

Royal Institution, Albemarle-street, W., 5 p.m. General Monthly Meeting.

Engineers, Society of, at the Geological Society, Burlington House, W., 5 p.m. Mr. R. H. Cunningham, "Some Engineering Work done by the 277th Railway Company (R.E.) in France and Belgium during the War."

Chemical Industry, Society of (London Section), at the Chemical Society, Burlington House, W., 8 p.m. (Joint meeting with the Faraday Society.) 1. Messrs. T. M. Lowry and F. C. Hemmings, "The Properties of Powders." 2. Messrs. T. M. Lowry and S. Wilding, "The Setting of Dental Cements."

Geographical Society, 135, New Bond-street, W., 8.30 p.m. Lieutenant E. W. P. Chinnery, "The Opening of New Territories in Papua."

TUESDAY, MARCH 2...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Colonial Section.) Mr. G. F. Scott Elliot, "Trade Routes for the Empire in Africa."

University of London, School of Oriental Studies, Finsbury-circus, E.C., 5 p.m. Mr. A. D. Innes, "The Mogul Period in the History of India." (Lecture IV.)

Royal Institution, Albemarle-street, W., 3 p.m. Professor A. Keith, "British Ethnology: the Invaders of England." (Lecture I.)

Alpine Club, 23, Savile-row, W., 8.30 p.m.

Röntgen Society, at the Royal Society of Medicine, 1, Wimpole-street, W., 8 p.m. Professor W. H. Bragg, "Analysis of X-Rays." (Silvanus Thompson Lecture.)

United Service Institution, Whitehall, S.W., 3 p.m. Anniversary Meeting.

WEDNESDAY, MARCH 3...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Mr. W. J. Garnett, "Mongolia from the Commercial Point of View."

Aeronautical Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Professor B. M. Jones, "Flying over Clouds in relation to Commercial Aeronautics."

Sanitary Engineers, 296, Vauxhall Bridge-road, S.W., 8 p.m. Captain R. L. Reiss, "Housing and Town-planning in Greater London."

Industrial League and Council, Central Hall, Westminster, S.W., 7.30 p.m. Mr. H. Atkinson, "Economic Production and Prevention of Waste."

Public Analysts, Society of, at the Chemical Society, Burlington House, W., 8 p.m. 1. Mr. C. A. Mitchell, "The Detection of Fingerprints on Documents." 2. Mr. C. J. Ward, "Photo-micrography with simple apparatus." 3. Mr. R. V. Wadsworth, "Note on the Solubilities of Theobromine."

Royal Archæological Institute, at the Society of Antiquaries, Burlington House, W., 4.30 p.m. Mr. M. C. Burkitt, "Some Unpublished prehistoric Rock-engravings from Russia."

Automobile Engineers, Institution of, at the Institution of Mechanical Engineers, Storey's-gate, S.W., 8 p.m. Mr. P. J. Worsley, "Gears and Gear Cutting."

THURSDAY, MARCH 4...Royal Society, Burlington House, W., 4.30 p.m.

Linnean Society, Burlington House, W., 5 p.m.

Chemical Society, Burlington House, W., 8 p.m. Lecture by Mr. J. C. Burnham.

Royal Institution, Albemarle-street, W., 3 p.m. Lieutenant-Colonel E. Gold, "The Upper Air—Modern Methods of Investigation and their Application in the War." (Lecture I.)

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Dr. T. M. Legge, "Guilds, Factories and Art."

FRIDAY, MARCH 5...Technical Inspection Association, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 7.30 p.m. Mr. W. L. Baillie, "Sampling: Some Problems and Fallacies."

Royal Institution, Albemarle-street, W., 9 p.m. Hon. J. W. Fortescue, "Military History."

University of London, University College, Gower-street, W.C., 5 p.m. Dr. T. Borenius, "Mediæval Art." (Lecture VIII.)

Philological Society, University College, Gower-street, W.C., 8 p.m. Mr. A. C. Wood, "Leicestershire Place Names."

Concrete Institute, 296, Vauxhall-bridge-road, S.W., 6 p.m. Mr. E. S. Andrews, "Some Properties of Steel."

SATURDAY, MARCH 6...Royal Institution, Albemarle-street, W., 3 p.m. Professor Sir J. J. Thomson, "Positive Rays." (Lecture III.)

Journal of the Royal Society of Arts.

No. 3,511. VOL. LXVIII.

FRIDAY, MARCH 5, 1920.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

WEDNESDAY, MARCH 10th, at 4.30 p.m. (Ordinary Meeting.) H. M. THORNTON, "Gas in relation to Industrial Production and National Economy." SIR ROBERT A. HADFIELD, Bt., D.Sc., F.R.S., will preside.

Further particulars of the Society's meetings will be found at the end of this number.

CANTOR LECTURE.

On Monday evening, March 1st, Mr. CHARLES FREDERICK CROSS, B.Sc., F.R.S., delivered the third and final lecture of his course on "Recent Research in Cellulose Industry."

On the motion of the Chairman, Mr. E. C. DE SEGUNDO, A.M.Inst.C.E., M.I.Mech.E., a cordial vote of thanks was accorded to Mr. Cross for his interesting course.

The lectures will be published in the *Journal* during the summer recess.

COLONIAL SECTION.

TUESDAY, MARCH 2nd; COLONEL SIR THOMAS H. HOLDICH, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., in the chair. A paper on "Trade Routes for the Empire in Africa" was read by Mr. G. F. SCOTT ELLIOT, M.A., B.Sc., F.R.G.S.

The paper and discussion will be published in a subsequent number of the *Journal.*

TWELFTH ORDINARY MEETING.

WEDNESDAY, MARCH 3rd; BRIGADIER-GENERAL SIR PERCY MOLESWORTH SYKES, K.C.I.E., C.B., C.M.G., in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Crook, Charles W., B.A., B.Sc., London.
Ford-Moore, Lieut.-Colonel A. P., London.
Frazer, E. D., London.
Hough, Lynn Harold, Evanston, Illinois, U.S.A.
Howes, George Henry, Wallington, Surrey.
Parnell, Edward, Sarawak, Borneo.
Richards, Herbert Edward, Marlow.
Tonamy, Chika Hira, Fushimi, Kyoto, Japan.
White, Edmond Aungor, Port Kembla, New South Wales, Australia.

The following candidates were balloted for and duly elected Fellows of the Society:—

Brunyate, Sir James Bennett, K.C.S.I., C.I.E., London.
Dongarsingh, Ramsingh, London.
Hunt, J. H., Dayton, Ohio, U.S.A.
Hutchinson, Lieut.-Colonel Thomas Massie, D.S.O., O.B.E., British Troops in France.
Layton, Gordon Shakespear, Bury St. Edmunds.
Mackley, Edward N., Gateshead-on-Tyne.
Needler, F., Hull.
Nelson, Amos, J.P., Thornton-in-Craven, near Skipton.
Parsons, Lieut. Percival A., A.I.F., London.
Peto, William, M.I.E.E., London.

A paper on "Mongolia from the Commercial Point of View" was read by Mr. WILLIAM JAMES GARNETT, First Secretary, H.B.M. Diplomatic Service.

The paper and discussion will be published in a subsequent number of the *Journal.*

EXAMINATIONS.

The number of entries received for the first examinations of this year, which commence on March 22nd, is 17,671. This is an increase of 5,709 on the corresponding examinations of 1919, when 11,962 entries were received.

The second series commences on May 10th, and the last day for receiving entries is April 12th.

THE ALBERT MEDAL.

The Council will proceed to consider the award of the Albert Medal of the Royal Society of Arts for 1920 early in May next, and they therefore invite Fellows of the Society to forward to the Secretary on or before Saturday, March 27th, the names of such men of high distinction as they may think

worthy of this honour. The medal was struck to reward "distinguished merit in promoting Arts, Manufactures, and Commerce," and has been awarded as follows in previous years :—

1864, Sir Rowland Hill, K.C.B., F.R.S.
1865, His Imperial Majesty, Napoleon III.
1866, Michael Faraday, D.C.L., F.R.S.
1867, Sir W. Fothergill Cooke and Sir Charles Wheatstone, F.R.S.
1868, Sir Joseph Whitworth, LL.D., F.R.S.
1869, Baron Justus von Liebig.
1870, Vicomte Ferdinand de Lesseps, Hon. G.C.S.I.
1871, Sir Henry Cole, K.C.B.
1872, Sir Henry Bessemer, F.R.S.
1873, Michel Eugène Chevreul.
1874, Sir C. W. Siemens, D.C.L., F.R.S.
1875, Michel Chevalier.
1876, Sir George B. Airy, K.C.B., F.R.S.
1877, Jean Baptiste Dumas.
1878, Sir Wm. G. Armstrong (afterwards Lord Armstrong), C.B., D.C.L., F.R.S.
1879, Sir William Thomson (afterwards Lord Kelvin), O.M., LL.D., D.C.L., F.R.S.
1880, James Prescott Joule, LL.D., D.C.L., F.R.S.
1881, Professor August Wilhelm Hofmann, M.D., LL.D., F.R.S.
1882, Louis Pasteur.
1883, Sir Joseph Dalton Hooker, K.C.S.I., C.B., M.D., D.C.L., LL.D., F.R.S.
1884, Captain James Buchanan Eads.
1885, Sir Henry Doulton.
1886, Samuel Cunliffe Lister (afterwards Lord Masham).
1887, Her Majesty Queen Victoria.
1888, Professor Hermann Louis Helmholtz.
1889, John Percy, LL.D., F.R.S.
1890, Sir William Henry Perkin, F.R.S.
1891, Sir Frederick Abel, Bt., G.C.V.O., K.C.B., D.C.L., D.Sc., F.R.S.
1892, Thomas Alva Edison.
1893, Sir John Bennet Lawes, Bt., F.R.S., and Sir Henry Gilbert, Ph.D., F.R.S.
1894, Sir Joseph (afterwards Lord) Lister, F.R.S.
1895, Sir Isaac Lowthian Bell, Bt., F.R.S.
1896, Professor David Edward Hughes, F.R.S.
1897, George James Symons, F.R.S.
1898, Professor Robert Wilhelm Bunsen, M.D.
1899, Sir William Crookes, O.M., F.R.S.
1900, Henry Wilde, F.R.S.
1901, His Majesty King Edward VII.
1902, Professor Alexander Graham Bell.
1903, Sir Charles Augustus Hartley, K.C.M.G.
1904, Walter Crane.
1905, Lord Rayleigh, O.M., D.C.L., Sc.D., F.R.S,
1906, Sir Joseph Wilson Swan, M.A., D.Sc., F.R.S.
1907, The Earl of Cromer, O.M., G.C.B., G.C.M.G., K.C.S.I., C.I.E.
1908, Sir James Dewar, M.A., D.Sc., LL.D., F.R.S.
1909, Sir Andrew Noble, K.C.B., D.Sc., D.C.L., F.R.S.
1910, Madame Curie.
1911, The Hon. Sir Charles Algernon Parsons, K.C.B., LL.D., D.Sc., F.R.S.
1912, The Right Hon. Lord Strathcona and Mount Royal, G.C.M.G., G.C.V.O., LL.D., D.C.L., F.R.S.
1913, His Majesty King George V.
1914, Chevalier Guglielmo Marconi, G.C.V.O., LL.D., D.Sc.
1915, Sir Joseph John Thomson, O.M., D.Sc., LL.D., F.R.S.
1916, Professor Elias Metchnikoff.
1917, Orville Wright.
1918, Sir Richard Tetley Glazebrook, C.B., Sc.D., F.R.S.
1919, Sir Oliver Joseph Lodge, D.Sc., LL.D., F.R.S.

PROCEEDINGS OF THE SOCIETY.

CONFERENCE ON HOUSE FURNISHINGS.

A Conference of Manufacturers and Distributors of House Furnishings, and of others specially interested in the subject, called by the Council of the Society, was held in connection with the Ideal Home Exhibition at Olympia on Thursday, February 19th, 1920, The Right Hon. Sir Auckland Geddes, K.C.B., M.P., President of the Board of Trade, in the chair.

The Chairman, in opening the Conference, said : Ladies and Gentlemen,—There is, I think, at all events one remark that one can make in these days without being contradicted by somebody who hears it, namely, that none of us like very much the present high cost of living. That means that if we wish to get rid of the high cost of living we have to develop the export trade on a far greater scale than we have so far achieved since the war. If we had the old pre-war scale with the present values I think the position would be very satisfactory ; but, as a matter of fact, we have not got the pre-war scale, and during the war we have been out of many of our markets overseas, with the result that those markets have—in part, at least—been occupied by our competitors. I hear from many of these markets the experience of the buyers of the goods which they have received from other countries, and that experience, broadly, is this—the goods which they are getting are quite good for the purpose when they get them, but they do not last so long as British goods. It is essential, therefore, that if we are to recapture those markets the whole quality of the goods which we send overseas should be better—if we can achieve that—than the goods despatched by any of our

competitors. Clearly the goods have to be in large volume, and that means quantity production. But we have to combine with that quantity production real quality in the goods themselves, and absolute fitness for the purpose for which they are intended. Not only have we got to get those qualities into the goods, but as a nation we have to produce goods which are pleasing in appearance and satisfactory from every point of view. It, therefore, is absolutely essential for us at the present time to combine all our forces—not only for the sake of our own homes directly, and for the sake of the articles which we ourselves use—but also for the sake of our export trade, upon which our comfort, our wealth, and the cost of living, so intimately and directly depend. It is, therefore, with the very greatest possible pleasure that I, as President of the Board of Trade, am here this afternoon at this Conference. We hope for great things from such conferences as these. We know the admirable work that has been done by the Royal Society of Arts now for many years. We have great hopes that the British Institute of Industrial Art will bring the craftsman, the designer, and the manufacturer together, and that the combined efforts of all our forces will have the result of placing us in a position in which we shall clearly be recognised in all the markets of the world as the leaders in intrinsic quality and the leaders in design. If by any chance we were to be driven out of our overseas markets we should, of course, be in a deplorable condition in a country such as this, where we do not produce enough food from our own soil to feed ourselves. One may, therefore, without exaggeration say that the sort of work that we are engaged upon this afternoon is of the highest national importance. Nothing could be more important than the achievement of the greatest efficiency for all our industries and for all our manufactures. I will not detain you any longer, but will now call upon Sir Henry Wood to address you.

Sir Henry Trueman Wood (Chairman of the Council): Ladies and Gentlemen,—The President of the Board of Trade has set us an admirable example in the brevity of his speech, and the amount which he crowded into a very few words, although I must confess myself disappointed that we did not hear more from so great an authority. I think my chief duty is to thank him, on behalf of the Council of the Royal Society of Arts, for lending his personal influence and the influence of his great Department to the movement which the Society is now doing its best to promote. But I should like, if you will bear with me, to say a few words about the work the Society has done and the reasons why it hopes to do more in the future. When the Society was first started in the middle of the eighteenth century the very first thing it did was to offer, amongst its other prizes, certain special awards for industrial art, and to lay especial stress upon the necessity of design in all those trades and industries which depend in any way upon ornament or decoration. The middle of the eighteenth century was not a favourable era for art in any form, especially for industrial art, and the Society of Arts was therefore like the voice of one crying in the wilderness. The public cared very little for applied art, and as a result the Society, following the direction of least resistance, drifted away to the encouragement of art pure and simple. For many years before the foundation of the Royal Academy, and until the Academy Schools obtained their deserved reputation, the Society of Arts was the one institution in England which promoted art education. For years it carried that on, though it never neglected its original and primary duty of the application of art to industry. I will not trouble you with the efforts it made in the first hundred years of its existence, but I will just remind you that one of the first things that Prince Albert, the Prince Consort, did when he became President of the Society was to tell a deputation from the Society that the most useful thing it could do would be to promote the application of the arts to industrial purposes. The immediate outcome of that suggestion was that a great many special prizes were offered and awarded for designs suitable for practical application, and the Society organised some very successful exhibitions, devoted entirely to ornamental manufactures. The ultimate outcome of the Prince's remarks was the great Exhibition of 1851, which, amongst all its other results, had a very remarkable effect upon the artistic manufactures of this country. As regards the production of furniture, I think the chief result was that our manufacturers produced a class of furniture of the very highest excellence, although it was distinctly deficient in original design. We never had a good British school of applied art, but we did succeed in producing admirable manufactures. One interesting evidence of this was that when our furniture manufacturers exhibited at Philadelphia in 1877, an enormous effect was produced on the manufacture of furniture in the United States, and the ultimate result was the production of a very large amount of excellent and very moderately-priced furniture by the application of machinery to the industry. I will not refer further to that point, but I should like to mention the work which the Society did for some ten years in the 1860's and 1870's by offering considerable prizes to art workmen. They offered amounts of about £600 a year, and they awarded prizes of about half that amount. A great deal of useful work was done, but I must say that the chief obstacle our predecessors found was the lack of any encouragement on the part of employers. The employers at that time were extremely reluctant to see the names of their workmen on the goods instead of the names of the manufacturers. I mention this fact because I believe that that feeling is not wholly extinct, and because I believe it is one which ought to be extinct, and I hope it will be before long. I will not trouble you by giving an account of what the Society has done during its existence—it would take too long

and it would embrace too much ancient history; but I can assure you that during the 150 years of its existence this old Society has done a great deal for the application of art to industry, and what I want to say now is that it is willing to do as much in the future. The Society is ready to place at the service of those industries where it may be useful its very widespread organisation and its very considerable influence. It hopes that the calling of this Conference together may lead to the holding of other meetings of employers and distributors in the particular industries in which you gentlemen are mainly interested, and in others also, and that the result may be the improvement of the articles produced and also an improvement in the economy of production.

We should remember that it is better for any trade to co-operate harmoniously in competition with foreign rivals rather than to encourage individual rivalry and competition among manufacturers. This is one of the objects of the Department of Industrial Research, in encouraging the formation of industrial associations in which rivals in trade are co-operating for the benefit of their trade, rather than working for what they consider to be their individual interests I hope that some such result may come from those conferences which will be the outcome of the present meeting.

Sir Frank Baines, C.B.E., M.V.O. (Principal Architect of H.M. Office of Works): Mr. Chairman, Ladies and Gentlemen,—I consider it is a very great honour to be associated at this Conference with the principles which I believe we all have at heart, namely, the desire to improve the standard of design and the method of production of the various articles utilised throughout the whole sphere of the building of houses. I think it is a very happy augury that this meeting has been called together by the Royal Society of Arts. I was going to refer to the history of the Society, but that has been done by the previous speaker, and I will therefore only raise one or two points which I think are of moment. For a period of 150 years the activities of the Society have been very considerable. During that time they have always been identified with the encouragement of arts, manufactures and commerce. The point I wish to make about the Royal Society of Arts was not made by the previous speaker, namely, that it was a private venture entirely supported and carried on by private funds without any assistance from Government. That, I think, is a point of very hopeful augury, and it shows what, unfortunately, we poor Government officials feel to-day—that institutions or movements promoted by Government are not of necessity the only movements which carry forward great ideas and give big results.

In its early days the Society of Arts gave premiums for drawing, and it awarded prizes for designs for weavers, calico printers, cabinet makers, and coach builders; and it also gave prizes to the manufacturers of iron, brass, china and earthenware goods. There, in my opinion, it was undoubtedly carrying out the direct idea which we have at heart to-day, namely, the material improvement of the general manufactures of this country; and it is a very happy augury to-day that we find this great Society, with its magnificent history, renewing its efforts to promote the applied arts of this country.

One recognises the absolute necessity of organised and sustained effort to improve the standard of industrial design, and we are called together to consider that problem to-day, and to review what in our opinion is tending towards assistance in that way and what is acting against it. To deal with the question thoroughly, I should like to obtain first of all a description of what an æsthetic standard is. The safest course to follow is to say that we will recognise the standard laid down by men of culture, men of knowledge, and men of training, and I think therefore what we should ask for is some scheme which will produce men of that calibre. Take the influence of the æsthetic qualities which we see so clearly in many of the productions of French applied art. There a point arises which I wish to bring very definitely before the manufacturers who are present to-day, namely, the paying quality of the æsthetic side of French products. I have met that aspect of the question all over the world; I have met it, unfortunately, in England, when, as a public official, I have been compelled to go to France for certain articles which I could not procure in this country. Does not that show that, once the æsthetic side of design, of standard of form, or standard of colour, is considered in the production of articles of utilisation in public buildings and houses, it is a very large step towards a considerable increase in the economic value of the goods, the extension of the market for the goods, and the establishment of a reputation which has a very high money value? We are often met by the answer of skilful business men: "We are interested in your ideas, but will they pay?" What I want to point out to-day is that they probably will. Certainly in the case of France they have paid, and in the case of England they have paid, as we realise when we think of the products of men like Josiah Wedgwood, and they will continue to pay in the future.

Then I think we must glance at what was the effect of the foundation of the Royal Academy in 1768. I think we can hardly claim that its institution had a material influence on industrial design. It has had a vast influence, undoubtedly, on the fine arts, but I see little sign of its influence on the applied arts. There is another body which has been formed recently, called the Design and Industries Association. That is a new Association, which has very noble

ideals, but I should like to ask whether any of the gentlemen in this room have ever gone to that Association and asked for its assistance and advice and taken its suggestions as to how they should deal with the problem of the design of the commodities which they are producing. I do not say that in any sense as reflecting upon the Association in question, but I say it as illustrating the fact that the associations and organisations available to deal with the objects we have at heart are not getting at the manufacturer. The Design and Industries Association is very modern; it accepts the application of modern machinery to manufactures and the possibility of utilising the highest principles of design in the manufacture of goods produced in bulk by machinery. That is a great advance, because so many artists and designers in the past have said: "We will not deal with goods which are produced by machinery; we will not soil our hands with them." That has been the great argument of the designer, and we have got to get over it; and I am perfectly certain, knowing the history of the Royal Society of Arts, that we shall never have cause to complain of it in that particular. Machinery has come to stay. Bulk production is the essence of our being, as our Chairman has pointed out to-day, more so now, perhaps, than ever. Therefore we have got to accept in principle that the standards of design and the suggestions which are made for increasing and altering those standards shall be applied to methods of manufacture to-day necessitated by the bulk production under which we live.

Then we have the Royal College of Art, which is a great institution; but here, again, its influence in relation to the applied arts has been meagre. It has not, in my opinion, utilised the great lessons which are almost at its elbow in that beautiful museum full of all sorts of objects and magnificent designs which directly deal with the question we have at heart. I feel that the criticism of the Royal College of Art is really contained in the report of the Departmental Committee which was appointed to consider its work. The following facts from that report are illuminating: 459 students went through the College. Of that number, 126 took to teaching, and only 32 took to practical design—roughly 6 or 7 per cent. of the whole; and if we tried to ascertain where that 6 or 7 per cent. are at this moment I do not know where we should find them. I am very certain that we should not find them helping the great manufacturers to improve the standard of industrial design. That rather shows us again that the work of the Royal College of Art, good as it is, is not assisting in the way wanted at the present moment. I hope it is not thought that I am reflecting in any way upon the great work of that College. I am simply pointing out that we cannot look to it to give us what we are aiming at here to-day. I feel that we have to strike out on new lines if we are to make history with regard to industrial design in this country.

The same criticisms which I have addressed to the Royal College of Art may be applied to the art schools generally. Students are undoubtedly not equipped for the business of taste in industrial design, and taste is a business in industrial design. It is not a question of pure initiative without training, without exact knowledge; it is a real business which has got to be learned like every other business. But, unfortunately, students are not learning the business of taste, and therefore we have to consider what methods we can propose and what courses of action are open to us to utilise that fine material which is going through the art schools year after year and not working on the problem with which we are dealing. The student has too often a contempt for tradition, and, unfortunately, he will not acknowledge the pure discipline of style. We are tainted with that practically universally in art matters to-day. A person who is not very far from me at this moment actually stated a point which I am now trying to bring out—namely, that it is vitally necessary to have originality in design. I agree, but I consider it even more vitally necessary to have a great tradition in design, a great knowledge of the historical standards of the past. I feel that an historical knowledge of style and an absolute grip upon the whole history of this country in regard to industrial design is far more essential than the originality which is called for as the first quality in students. After all, bearing in mind that ours is a fairly old country and that it is full of magnificent buildings of all periods and styles, and that our pictures, furniture, and Sheffield plate are part of the country, why should we discard them all and say: "We want to be original; we want new art; we want the individual man who produces what is in his brain, and we do not want what has been produced by the great men in the past"? I am sure that in that direction failure lies.

Now we come to the Arts and Crafts movement. I do not know what I am to say about that without raising a great deal of criticism. The very phrase brings up to me appalling pictures. I have bitterly suffered from that movement. I remember when I was quite a young man having to sit upon carved chairs, the seats of which were uncomfortably decorated with Tudor roses. Further, I remember being at dinner and trying to cut the ordinary beef, which in those days was much more tender than it is to-day, and failing because I had an instrument which was a production of the Arts and Crafts movement. Again, I have seen pewter plaques on the ceiling through which the wires were suspended for the electric light lamps. Now pewter is a metal which flows rather readily, and after a few minutes those plaques looked as though they had been knocked

about by all the children of the household. That is my personal experience of the Arts and Crafts movement, which may perhaps be a very unfortunate one.

I feel that we shall have to discard this movement for increasing the activity of industrial design. We have to go hand in hand with you hard-headed manufacturers, you men who produce the goods and who ask us awkward questions.

What have the Government done? Have they helped us in this matter? Are they moving on the lines which we have at heart? Do they show any signs of activity which will really give us a vast improvement in industrial design? Our Chairman has told us in his opening remarks how important it is to increase our export trade, not only in bulk but in quality. I say that that increase in quality can only come about by carrying forward the principles of bettering the design and standards under which articles are produced. What have the Government done? I am a Government official and therefore naturally I shall try to make as good a case as possible for them, but I am afraid I shall fail. As far as I can understand, the Government have subsidised schools of practical art. I have tried to get a definite record of what the accomplishment of these schools has been, but there again I have failed, and I can find very little sign of any influence of those schools promoted by the Government. The Government have also awarded medals and diplomas, but when I investigate the whole matter and ask what the result is I become depressed..

What have the manufacturers and distributors done? These are the men who say: "We are perfectly happy; we are delivering the goods. We can make what we like and sell what we make." They are lucky fellows, and they will be lucky for the next two or three years. After that I hope they will be a bit unlucky, because that is our only hope. What has the manufacturer done? All I can do is to go to his catalogues. I have a room full of them which I have to look through occasionally, and a more abominable list of examples I do not think it is possible to conceive. There is hardly a redeeming feature in them. The only thing that the manufacturer does in regard to his catalogues is to make up for quality by quantity. That is his standard. This matter is important and serious, and I have not said what I have said about the manufacturer without cause. If any manufacturer here has a grievance against me, let him come to my office and I am sure he will say worse things about these catalogues than I have done. My method will be to show him what the other fellow has done, and then if the other fellow comes I will show him what the first man has done, and he will criticise, and I shall get agreement on that basis. But the manufacturer undoubtedly has neglected to improve his designs by the selection of innumerable old examples which exist from the seventeenth and eighteenth centuries. He simply says: "The public want something new; I think this will fetch them." Where he gets his designs from I do not know. I think we can fairly come to the conclusion that, if the societies and institutions and the Government have failed, the manufacturer has also failed, and he is failing to-day. But he is such a good fellow that we cannot let him go without a tear, and we hope that our tears and our efforts for his regeneration will spur him to make an effort to improve and to raise the standard of articles which he produces. Another great fault of the manufacturer is this. He will produce a certain article—for instance, fire-grates. He will go to one man to produce the fire front; he will go to another man to produce the fender; he will go to a third to produce the coal scuttle, and so on; and in that way you get a most glorious heterogeneous collection when you bring them together in a room. We have the misfortune to live with them, and we are here to-day to lead the revolt against life under that standard. We think of the exquisite patterns of Chambers and the Adams, and the early grate-fronts produced by the Carron Company, and we compare those things with what we have got to-day. I dare say every one of us is familiar with the patterned oilcloth which is one of the abominations of domestic life. There, again, the manufacturer may say: "This is the fault of the designer." I say: "You have chosen the wrong designer." It may be that the designer has been wrong, because the designer in most cases will very rarely rule himself out and say: "You do not want design there; you want plain colour and plain surfaces." But even then the manufacturer has not been able to get rid of the designer and do away with those patterned oilcloths which are a monument of British philistinism throughout the world. Take, again, the *repoussé* copper curbs and hearth furniture that we see; they are the most appalling things, and one meets them everywhere. The manufacturer says: "We are doing very well on them, and we do not want any interference." What we say is this: "We want you to do well; you are assisting the country by your progress, and therefore your progress is what we have at heart; but we suggest to you that you can get that same progress better by raising the standards and by altering the products which you have made in the past."

Is there no credit side to this rather unhappy and pessimistic account? I hope there is. We have the new British Institute of Industrial Art. I feel it has possibly a great future before it, and the Chairman could doubtless tell us a great deal about the proposals which he is putting forward and considering for its extension and for the furtherance of its activities.

Then we have the Royal Society of Arts with us, and the incentive which has been given to the movement by the Society calling this Conference here to-day. In the past the Society has awarded prizes to Minton and Co. for pottery; Osler and Co. for glass; Woollams and Simpson for wallpapers; the Coalbrookdale Co. for iron castings; and Crossley for carpets. These firms have produced fine articles, and we know perfectly well that they can produce them again. We also know that the Society helped in the production of these fine articles. We want them to help again. That is an undoubted example of the influence of the Society directly upon the lines which we have at heart. But there is one point that I want to warn the Society about, and that is that, curiously enough, the standard of industrial design has consistently declined during the period which closely corresponds with the activities of the Society. For the last 150 years the standard of industrial design has fallen. The causes of the decline, however, are deeper than anything to do with this Society. They are the decay of handicraft consequent upon the introduction of machinery, the amazing commercial expansion which is one of the most astounding factors of the commercial history of the world, the industrial revolution from 1760 to 1830, and the vast activity which shows such little signs of cessation to-day. The manufacturers for the last 150 years have been engrossed in this tremendous commercial expansion, to the exclusion, as a rule, of purely artistic considerations; but one of the greatest items on the credit side, in my opinion, comes from the manufacturers themselves. One of the most hopeful signs is to note the work of men like Josiah Wedgwood and Matthew Boulton, the founder of the famous Soho works at Birmingham. They produced work of an extraordinarily high standard—work which at that day was produced by means of mass production, and yet which came up to the very highest standard of artistic excellence as well as workmanship. British manufacturers have themselves given us the keynote as to what can be done, and all we say is: "Do it again." Consider the great potter Wedgwood and what he did; he developed a business of enormous magnitude which has been continuously increasing. He added vast industries to the resources of the country; he materially increased our foreign trade, and he also produced works of pure excellence and design unparalleled in the history of British commercial production.

I suppose we ought to refer to the influence of Ruskin on the movement. Although it is very difficult to trace his influence on the actual production of artistic commodities of British manufacture, there is not the slightest doubt that it was very great. He had the enthusiasm of a man of genius, and in his writings he consistently aimed at the best. But the man who did more than Ruskin was William Morris. There we have a man who showed tremendous activity in stimulating and fostering a dozen industries, a man of overpowering individuality who achieved impossibilities. Other names might be mentioned, such as the brothers Adam and Chambers. But, generally speaking, reviewing the whole position to-day, I think we may say with absolute fairness that the condition of industrial art is chaotic and lamentable in the extreme, and, what is more lamentable still, there seems to be little desire to improve it.

This brief review seems to me to show that manufacturers, the Government, and the public, are united in a sort of tripartite blame, and that being so it is no good for us to fold our hands and say: "We are all bad fellows; let us remain bad," and therefore we have to form a mutual encouragement society. The manufacturers' reply will be: "The Government have failed to assist us. We are simply asked to carry out the requirements of the public. The public will have what they want. Our success is due to the fact that we give it to them." I think that argument wants a lot of examination. I have been told by someone that it is very dangerous in addressing manufacturers to deal with the word "art." He said: "The word 'art' is anathema to the manufacturer; I should keep off it if I were you." I do not believe the manufacturer is quite as bad as that. His pocket is too well lined to fear any of my criticism, but I do feel that if we approach him and assure him that art is nothing but a standard of pattern, of form and of colour, and that it is an offshoot of science, he will take a different view. If we plunge into the principles which direct æsthetics we shall find that they are resolvable on a scientific basis. It seems to me that, if it was looked at from the point of view of being an ordinary everyday proposition to set up a definite standard of pattern *qua* quality only, the manufacturer would not be so nervous of the word "art" in industrial affairs. The word "science" does not seem to frighten trade or the Government. The Government has done great things for science and industry to-day. It has promoted a Committee of Scientific and Industrial Research, which is prepared to appoint special committees to go into any question of science raised by any trade of the country. It has at its disposal that great educational institution, the National Physical Laboratory, and it sends there for examination and for research any problem which trade and commerce may address to it. Here we have an example of the way in which the Government and trade generally appreciate the importance of co-ordinating under one body science as applied to trade. Is it not necessary, therefore, to consider the advisability of promoting such a co-ordinating authority with regard to art in trade and industry? Whether it should be promoted under Government auspices or not is a doubtful question—I am not prepared to

say. I know the suspicion which seems to exist of late with regard to Government movements on the part of industry and trade. Undoubtedly that is justified on many lines. Bureaucracy is walking very tenderly to-day.

What is the real solution? Is it in a Ministry of Fine Arts? If it could act on the lines of Colbert, the great Minister of Louis XIV., a Ministry of Fine Arts would do invaluable work for the nation, but I am rather inclined to think that such an organisation is not suited to us. In the next place, is the solution in intelligent Government support? I am sure the answer to that is in the negative. Is the solution in the extension of the powers of the British Institute of Industrial Art? That is a new body which it may be will break new ground and make history. I hope that we shall see in that Institute a real attempt to deal with the problems which we are talking about to-day. A question is whether the art schools can be brought into closer touch with employers of labour in industry, whether the cure is in a new system of technical education, or whether reliance can be placed upon the new vigour of the Royal Society of Arts. Every effort will help, and we cannot afford in such a vast field to discard any influence which is working towards the end we have in view. I am inclined to think that the answer will be: "Manufacturer, heal thyself." He has done it in the past, and I am inclined to think he can do it again with regard to the standard of industrial design. My proposition, therefore, is rather on these lines: That the trade and society generally shall say: "This proposition is important to us and we are prepared to go into it ourselves. We will investigate it ourselves. We will see whether we cannot support our own movement and rejuvenate ourselves, as we have done in the past." That, I am inclined to think, may be the solution, and it is a solution which would be a very happy augury for the future, because it is on the direct lines of purely individualistic expansion of British trade generally.

I have been asked to move a resolution embodying more or less the principles which I have enunciated, and which may come out of the discussion that will now take place. For the purpose of offering some sort of sop to the meeting or some bone to gnaw at, I move this resolution, but I want it to be understood that it is not necessarily a definite one; it is subject to suggestion and argument on the part of any of those present. I move:—

"That this Conference expresses its appreciation of the efforts which are being made by the Royal Society of Arts and the British Institute of Industrial Art to extend the use of art in industry, and is of opinion that a small general committee should be formed, under the auspices of the Royal Society of Arts, containing representatives of the various trades concerned, to investigate further with a view to securing a concrete issue of the propaganda undertaken by the Society."

The Chairman: Ladies and Gentlemen,—I am sure we all feel there is plenty of matter to discuss—that there is not only one bone to gnaw at, but a handful of bones—in fact, I think there is a bone apiece all round. I hope that you will take part in the discussion on the resolution which has been moved by Sir Frank Baines. I am now going to ask you to excuse my further attendance at the meeting, as I have another important engagement to fulfil. I should like, before I go, to express my intense interest in what I have heard here to-day, and further to express the hope that out of this Conference some good will really come. I now ask Sir Frank Baines to take the chair.

Sir Henry Trueman Wood: Before Sir Auckland Geddes leaves, I am sure it would be your desire, ladies and gentlemen, to accord a hearty vote of thanks to him for presiding over the meeting.

The chair was then vacated by Sir Auckland Geddes and taken for the remainder of the meeting by Sir Frank Baines, C.B.E., M.V.O.

DISCUSSION.

Mr. Charles Tennyson, C.M.G. (Federation of British Industries), in opening the discussion, said he desired to confess at once that he represented a large organisation of manufacturers, and he said so without shame, because he thought the blame in the matter lay not with the manufacturers but with the public. The manufacturer was tied hand and foot by the public in two ways. First of all, the shares in manufacturing companies were held largely by the public; in the second place, the manufacturer had to persuade the public to buy his goods. It had been said that when the public was given a choice between a good thing and a bad thing it would choose the good. He regretted to say that that was not the fact. If it were, it would be necessary to postulate that the standard of taste of the manufacturers and designers was below the standard of taste of the public. So far as the manufacturers were concerned, he said nothing, but so far as the designers were concerned he thought that could hardly be maintained. Undoubtedly the great public bought the worst works of fine art, and, bearing that fact in mind, it could not be said that the public unerringly chose the good when it was given a choice. There was a public which chose the good, but it was a small one, and that public was faithful to high ideals. But a small public was of no use to the manufacturer who had to concern himself with bulk production, and that was the great problem the manufacturer was up against at the present time. There was one customer who could practically dictate the terms

upon which he would buy and who could order in bulk, namely, the Government, which Sir Frank Baines represented. He thought the Government might take a very useful step in the matter if it made it a part of its pronounced policy that it would only buy good designs, that it would take proper advice as to what were good designs, and that it would not mind paying a little more when it got them. The Government should so formulate its policy that it would enable manufacturers to make what the Government wanted in bulk, and if that were done he thought it would be a very long step in the right direction, and that the organisation which he had the honour to represent would co-operate in every way with the Government to further that end. The problem was a very new one. Design originally came out of craftsmanship, *i.e.* the man had his tools and his materials, and out of the use of those two things designs spread. At the present time, however, the machine had taken the place of the tool, and that could not be run without a huge organisation and a great many workers and directors. The problem at the present moment was how to get the craftsman's mind to operate with that machine, and so far as he could see there were only two ways of doing it. The first would probably be done if there was a great collective æsthetic spirit in the country. If the whole country knew what good design was and wanted it, that æsthetic spirit would operate on the machine and a new craftsmanship of machine would be obtained. But he was afraid that was 100 or 150 years off. The only other way in which it was possible to bring such a state of affairs about was if the manufacturers would take a leap in the dark, and, chancing whether they would sell their product, say: "This is a matter of art and of æsthetic quality in a special line; we do not understand it; we only know what we can sell; but we are told that for the good of the public we ought to do something better. We will go to those who understand it, and take their advice." If every manufacturer in a large way would try to get into touch with some artist of standing, originality and practical sense, and give him a fine position in his works, he thought some good would result. Every manufacturer should have an art director just as he had other kinds of directors. As an instance of that he thought it would be of interest if he stated that he was recently informed that in a large retail firm in New York the head window-dresser was paid the largest salary next to the managing director. That was the kind of position he would like to see an artist occupying in some of the factories of this country.

Mr. Marshall Roberts suggested that the Government should hold exhibitions every year at which the manufacturers, workers and artists could exhibit their wares, and, if necessary, sell them. At any rate, they should be well rewarded for having produced works of art in the way of furniture, carpets, and every other article that was required for the furnishing of an artistic home. If the Government held such an exhibition and offered substantial prizes, he felt quite confident that better taste in the British home would result.

Mr. H. E. West Taylor (Secretary, London Cabinet and Upholstery Trades Federation) said he was sure most of those present agreed with Mr. Tennyson's remark that it was utterly useless to blame the manufacturer. He did not know whether the Chairman remembered the class of song which was rather popular at the time when they were boys, but he recalled one song in particular by the late Corney Grain, about a little boy in a white surplice, one of the verses of which was :—

"And when he sang in choruses
His voice o'ertopped the rest,
Which was very inartistic,
But the public liked it best."

So far as he was concerned, that entirely summed up the difference between the Chairman and the organisation which he (Mr. Taylor) had the honour to represent. It was not the slightest use asking the manufacturers to lead the public. Manufacturers were far too busy with labour troubles, apart from anything else at the present moment, and with other matters which were loosely dealt with under the comprehensive title of "reconstruction," to educate the public. Manufacturers would supply what the public asked for if the public was taught to ask for the right thing. A very great number of cabinet shops in London, on behalf of which he had the honour to speak, employed very large staffs and very expensive designing departments, so that the accusation which had been made that manufacturers neglected that side of their business was entirely unfounded. A great deal had been heard about the British Institute of Industrial Art. As Secretary of the London Cabinet and Upholstery Trades Federation, representing the whole of the manufacturers of furniture in London, that Institute had never been brought officially before his notice, and if that was the case, how was it possible for manufacturers to take advantage of whatever facilities such institutes afforded? He maintained that if the Government desired co-operation between manufacturers and any particular institute, the first step that should be taken was to acquaint the associations of the manufacturers of the existence of such an institute, and afford the Federation the opportunity of expressing their opinion. He suggested that the proper method to adopt was for the Government to get into touch with the manufacturers through their associations, and to spend their time and money,

not in slanging the manufacturers but in educating the public.

Mr. S. D. Bianco, speaking as a cabinet maker, suggested to Sir Frank Baines that in looking at manufacturers' catalogues he must have noticed in recent years that great improvements had been made. Although the public perhaps had not asked for improvements, the manufacturers themselves had certainly improved their designs of late years, particularly since the time when Messrs. Waring came to London. That firm instituted one of the finest studios, and since that time the design and production of furniture in general had been greatly improved. All manufacturers could not hope to be Waring and Gillows, but, on the other hand, the manufacturers in general, whether in London or out of it, were engaged in producing what he called very creditable replicas of the old masters; in fact, in some cases some of their products were better than the old examples. The designers who had been trained in the various manufacturers' studios during the last ten or fifteen years were very smart men, and there were a number of excellent designers now coming along. So smart were they that the American retailers in particular came to this country and tempted them to go to America. That was particularly the case before the war, when some of their best men were induced to go to America by firms who did not mind paying any price in order to get the best brains. But a large number of excellent designers still remained in the country. Manufacturers were doing their very best at the present time, and had succeeded in bringing the furniture of this country out of that nasty period which used to be called Louis and Chippendale with a lot of icicles on it, and the vile old oak things that used to be seen in Wardour Street. All that had been killed, and even in the much-abused East End of London the Sheraton style—locally known as "Sheridan" style—had been killed, and they were now making Adam, Chippendale, and other good reproductions. He did not think the manufacturers deserved the scolding that had been given to them by Sir Frank Baines.

Major A. Longden, D.S.O. (Director of the British Institute of Industrial Art), in reply to Mr. West Taylor, said the reason the Institute had not come in touch with all the manufacturers was, first of all, that it only received its Articles of Association eight or nine days ago. Since then he had visited the trade in Manchester, Carlisle, Bridge of Allan, Stirling, Glasgow, Edinburgh, and Stoke-on-Trent, including that most excellent firm of Whittick and Reid, at Edinburgh. A finer firm of cabinet makers and manufacturers could not be found. They were turning out splendid trade productions, designed by Sir Robert Lorimer. Doubtless he would have the privilege of visiting all the manufacturers in time, as he did not intend to sit in an office during the period he held the post of Director, but it was very difficult for him to visit everybody. He suggested a better plan would be for the manufacturers to come and see him at 217, Knightsbridge, where the Institute would then place at their disposal all the information they required. The Institute would very much like to help in regard to the excellent remarks made by the last speaker about icicled Chippendale, and it was only through conferences such as the present one that it was possible for the Institute and the manufacturers to get into real touch with one another. The Institute hoped to be able to form some link which would be of use for the purpose of spreading information from abroad. Through a bureau of information the Institute was now getting from our consuls samples and photographs of the articles that would sell best abroad, and it was hoped to have not only an exhibition in London which would be open all the year round, but exhibitions in the provinces on the lines run so well by the Design and Industries Association. With regard to trade catalogues, which had been severely dealt with by Sir Frank Baines, the Institute was making collections of the best catalogues in the country, and they could be seen by all those manufacturers who cared to inspect them. He agreed in general with the statements the Chairman had made in that respect, but there were exceptions which held their own against any catalogues in the world. It was necessary, however, for a meeting such as the present to co-operate with the Institute if they were to help one another to bring about a better state of affairs. If the Institute could not give the manufacturers what they wanted at the moment, it was the Institute's business to get it, and that was his instruction to the officials who were in charge of what was called the Bureau of Information. The first exhibition of the Institute, which would be opened in May, would be of furniture, textiles and ceramics, and he had no doubt the manufacturers concerned would apply to him for further particulars of that exhibition.

Mr. E. J. Brown (of Messrs. W. Lamb and Co.) said there had been a good deal of abuse of manufacturers for the bad catalogues and bad furniture they produced, but the last speaker had said he had seen some fine furniture in Scotland. Those manufacturers who were engaged in his class of business required information in regard to well-designed articles, at a price which was not prohibitive, suitable for young people who were getting married at the present time. All the designs of Sir Robert Lorimer and all the scolding of manufacturers for the catalogues they produced would not meet that demand. The manufacturers he represented desired a lead as to the

way in which it was possible to do their present business—namely, how to manufacture furniture for the public on simple lines and in an artistic manner. They did not want to hear so much talk about artistic stuff; they wanted not so much talk but a little more "do." There should be more co-operation between all those concerned in order that good, strong, and well-made furniture of good design should be produced at a moderate figure, so that young people who wished to get married could do so.

MR. PERCY A. WELLS (Head of the Furnishing Department, Shoreditch Technical Institute) said he desired to ask whether it was the fault of the public or of the manufacturers that there was not a single cottage in the Ideal Homes Exhibition suited to the taste or to the purse of the cottager. The public were invited to go into artisans' cottages which were furnished with most expensive eighteenth-century furniture. In the cheapest cottage he saw a wardrobe standing on the landing priced at £20. In going into a seventeenth-century living room, however, the impression instantly produced was that of homely dignity and comfortable homeliness. He did not for one moment maintain that the furniture was suitable for modern requirements, but he hoped some endeavours would be made to get back to something of the simplicity and the homeliness of that furniture for the furniture of the new cottages. He suggested that architects who built cottages, particularly near to large centres of industry, might call together a committee of cabinet makers, ladies, and other people interested in the movement, and invite the local manufacturers to furnish a cottage with simple and cheap furniture which was pleasant to look at and fit for its purpose. Cheap articles need not be so atrociously ugly as they were at the present time. It was difficult to say whose fault that was, because there were so many people concerned, but he believed that if the public made up its mind on certain simple principles in buying furniture—for instance, that it should be fit for its purpose, that a sideboard should be a sideboard and not something with bits of carving and plate glass all over it—a practical step would be taken in the right direction. Moderately cheap furniture could be made which was pleasant to look at, and which was nevertheless substantial and sound, and there were plenty of designers who could design such furniture if the manufacturers would only pay them to do so.

MR. D. M. DAVIES inquired whether anybody in any other country in the world had ever seen furniture designed on such beautiful lines as English furniture, and whether any other country produced furniture of such simple and beautiful construction. Personally, he did not know of any other country where furniture was made in anything like the quantity or quality in which it was made in England. The whole world came to England for its furniture, although they had forests at their elbows. Nevertheless, they sent their timber to England and re-imported that timber in the manufactured state as furniture. That pointed to the fact that English manufacturers must give a certain amount of time to design alone. There were present at the meeting some of the leading manufacturers of furniture in England, whose designs were recognised throughout the world, and he did not think they could be improved upon. It was really only a question of providing cheaper lines of furniture of better design, and that was simply a question of price. So far as catalogues were concerned, it was almost an impossibility for a firm to catalogue the choicest of its designs, inasmuch as the majority of furniture made in high-class shops was repeated only once or twice. The design did not lend itself to being repeated over and over again, nor was it possible to sell large quantities of furniture designed on such high-class lines. If Sir Frank Baines would write to some of the English manufacturers and ask them for private photographs of their highest class furniture, he did not think he would be disappointed. He was very much afraid that the public, and probably foreign buyers, were educated by the catalogues that were published. That was rather foolish, inasmuch as no producer of first-class cabinet work in this country would dream of cataloguing all his designs. He would not pay a large sum of money for the brains of a good designer, and then give the benefit of them to the whole of his competitors. That was not business, nor was it reasonable.

ADMIRAL L. G. TUFNILL, C.M.G., said that, as an absolutely impartial and unbiased member of the public, who knew nothing whatever about the trade except that he occupied the unfortunate position of occasionally having to buy furniture, he desired to support the remarks made by Mr. Wells in regard to cottage furniture. He owned a few cottages and lived in the country, and was only too anxious, as he had always been, for the welfare of those who worked for him. It was altogether impossible and impracticable to put in a cottage the furniture seen at the present Exhibition. A great many improvements might be made. For instance, although furniture might be cheap it need not be repulsive, and many useful little details in connection with cottages not shown at the Exhibition might be incorporated with the greatest benefit. Many little economies could be introduced in connection, for instance, with fireplaces, which would make an enormous difference in the comfort and living of the occupiers of the cottages and smaller houses in England.

MR. JAMES SMELLIE said that to understand the difficulties of manufacturers in reference to design, it was important to realise how the trade was carried on. Some years ago he propounded a scheme which, it seemed to him, was as practical at the present moment as it was then. The furniture of a particular room was probably produced by five or six different manufacturers, and if it was desired that the furniture of a room should be properly designed it was necessary that a master designer should design all the furniture, separate firms, if necessary, making particular articles. If a Government department did the designing and left each manufacturer to deal with his own section, when the furniture dealer had to supply furniture for a complete room, although he bought the articles from half a dozen different manufacturers, the furniture would all be of the same design. The articles would also be produced at an economic price, and there was a reasonable chance of getting a house well furnished without having to pay an exorbitant sum. On the other hand, anybody who desired to furnish a room at the present time had to employ a special designer, and the goods were produced at a greatly increased cost. If a design could be fixed and the articles made at a reasonable price, the proposition would become a practical one; but at the present time too frequently goods were made in very small quantities. If the goods were produced in large quantities, the percentage of profit could be reduced. The first essential was to educate the salesman, who had a great deal of influence over the public. If the salesman was educated to understand the difference between goods that were well-made and well-designed and those that were not, he would have a great influence on the buyers, and struggling manufacturers who were trying to produce better designed goods would have a chance.

MR. H. T. KEMP suggested that the industry would be much improved if poor inventors were assisted by the Government, as they were by other Governments. In this case much better work would be done for the community, because, unfortunately, it was too often the case that it was useless for a man to have brains unless he also had money.

The resolution set forth on page 254 was then put and carried unanimously, and a vote of thanks having been accorded to Sir Frank Baines for his conduct in the chair, the Conference terminated.

A NEW ARABIAN RAILWAY.

A railway from Aden, the principal port in Arabia, to Lahej, the capital of the Abdali tribe in south-western Arabia, was opened last year. The line is about thirty miles in length, and is the development of a short military line built from Aden to Sheik Othman in 1915, to supply British forces operating from the latter place against the Turks. After the signing of the Armistice, and the surrender of the Turkish forces, the railway was continued to Lahej.

The line is a narrow-gauge one, the equipment being largely from the old Bombay, Baroda and Central India Railway. All the way from Aden to Lahej the track is laid over fairly even ground, and the elevation increases very gradually. There are no bridges and few culverts. To Sheik Othman the distance is about nine miles, and Lahej is about fifteen miles farther, over fairly level desert of shifting sand. Approaching Lahej, the sandy surface becomes harder, and there is extensive cultivation by irrigation through the use of the limited supply of water from the Tiban River, which comes down from the Yemen Mountains and divides five miles before it reaches Lahej. Dates, grains, melons, and vegetables are the principal crops in the Lahej delta.

In normal times Aden, where nothing grows, was able to draw some supplies of vegetables and other fresh foodstuffs from Lahej. These supplies then came in by camel caravan, but can now come in more cheaply and more quickly by the railway. Aden will thus benefit directly by having available a more plentiful supply of grain and other fresh foodstuffs.

Lahej has also been a centre for the collection of considerable quantities of goat and sheep skins, hides, and coffee, coming down by caravan from the fertile Yemen country to Aden for purchase by exporters. From Lahej to Aden the only method of transport was by camel caravan, and in the last normal trade year the Aden Port Trust statistics show that an average of nearly 500 camel loads of produce per day came into Aden by caravan. Some part of these loads came from the east, but a good share of them came in *viâ* Lahej. Over these same caravan routes there was exported annually from Aden to the interior, in normal trade years, practically 500,000 dollars' worth of cotton piece-goods, raw tobacco, spices and grains. The number of camel loads (a camel load averages round about 400 lb.) of exports is not ascertainable, but it was large, judging from the value of the goods carried.

Aden is the first of all Arabian ports, and is further important as a commercial centre for the collection and distribution of goods from and to the territories on both sides of the Red Sea and the Gulf of Aden. Owing to its superior advantages as a port it has long received a large share of the skins, hides, coffee, and other produce from the Yemen and other less important parts of the hinterland. The centre and capital of the rich and watered Yemen plateau is Sana, which is about 200 miles north of Aden. Trade by caravan between Sana and Aden is said to have existed for many centuries, but in recent years, when speed in getting products to the coast has become more essential, some of the caravans have changed over from the Aden route to Hodeida, a port north

of Aden, on the Red Sea, and about 150 miles from Sana.

Hodeida has been Turkish, and Aden has been and is British, and there has in recent years been much conjecture as to whether, by improving the former port and having better communication with the interior, it might not be possible to divert from Aden some of the business done by it with the Yemen. To this end a railway from Hodeida to Sana was begun in 1906 by European engineers, using Turkish capital. Only a few miles of track were laid when the work stopped, and great supplies of railway material which had been brought in have since lain rusting on the shore near Hodeida. The matter of a railway from Aden to Sana had often been talked of, but owing to the longer distance, as compared with Hodeida, and the possibly greater engineering difficulties when the mountains should be reached, no active steps to build such a line had been taken. As already stated, the necessities of war resulted in the beginning of the Aden-Lahej railway, and as the start has been made with thirty miles of track it may be possible to develop sufficient interest to continue for 170 miles into Sana.

According to a report by the United States Consul at Aden, from which the foregoing particulars have been extracted, the possibilities for profit in extending the railway on from Lahej into the Yemen Mountains, and possibly to Sana, would seem most promising. The Yemen plateau is well watered because of its altitude, and the soil is said to be fertile. This district produces the world's supply of genuine Mocha coffee, and many kinds of grain are successfully grown, while tobacco, indigo, cotton, fruits, and vegetables are also produced. Large herds and flocks of cattle, sheep, and goats are kept and supply an important quantity of hides. Mocha coffee, the skins known to the trade as mochas, and hides and skins from the Yemen would seem to be the most important products of commercial interest.

While the quantities of these products hitherto supplied have been considerable, they have naturally been limited by the difficulties of getting them to the coast for export, and by the further fact that the Arab farmer has had to devote much of his energy and attention to producing, as well, his own food supply. If he could get food from the outside, which would be feasible if a railway were built, he would have more time and energy to devote to producing greater quantities of the, to him, more profitable crop of fine Mocha coffee. He would incidentally want, and be able to buy, greater quantities of cotton piece-goods and other manufactures from the world markets. The above considerations suggest, briefly and generally, the possibilities offered to an extension of the Aden-Lahej railway to Sana; particularly as the Hodeida-Sana railway enterprise has for some years been abandoned, and is now obviously at a disadvantage as compared with the Aden-Sana projects, Hodeida having been seriously damaged by bombardment during the war.

Engineers connected with the Aden-Lahej railway say that from the engineering standpoint the construction of the line to a point fifty miles beyond Lahej would not present great difficulties, but that the remaining 120 miles to Sana, being through mountainous country, would undoubtedly present difficulties, although the route has not been surveyed. As the Yemen country is said by travellers to resemble mountainous Abyssinia in many ways, it is unlikely that the physical difficulties of building a railway through the mountains would vary greatly from those comparatively unimportant ones of the route over which has been built the Franco-Ethiopian railway from Jibouti to Adis Abeba, 500 miles in length.

UTILISATION OF FISH OFFAL IN BRITISH COLUMBIA.

A comparatively new industry has been established in British Columbia at Tucks Inlet, across the bay from Prince Rupert, in Osborne Cove. The company which established this industry is known as the Tucks Inlet By-Products Company, a Canadian organisation with a capital of 125,000 dollars, and with head offices in Vancouver.

The products of this concern are obtained entirely from fish offal. The company manufactures fish meal, which is a valuable fertilising ingredient, and fish oil, which is used in the manufacture of soap. In the opinion of the Company's manager, writes the United States Vice-Consul at Prince Rupert, this oil can be used in the manufacture of glycerine also. The offal is obtained from the various canning plants along the Skeena River and from the Prince Rupert fish-packing companies. This plant in reality serves a double purpose, inasmuch as it produces a marketable product of very considerable value from an otherwise worthless raw material, and at the same time disposes of offal that would be a nuisance in a community where fishing is the most important industry and canning establishments are so numerous.

The offal is collected from the various canning plants and packing houses and conveyed to the fertiliser plant. Upon arrival the offal is hoisted to the top of the factory to the storage hopper, from which it descends through the various cooking and crushing machines to the basement. This operation is repeated, and after the oil and moisture are extracted the residue constitutes meal ready to be used in fertilisers.

As the offal fats are contained in oil cells or tissues, the offal used for oil is heated or cooked in order to break up these cells. Then the moisture and oil are pressed out and separated and the oil refined.

The oil is placed in storage tanks at Prince Rupert and transported in tank cars *viâ* the Grand Trunk Pacific Railway. Fish meal is shipped by steamer direct from the plant. Both oil and meal are sent principally to the United States, the former to Chicago and vicinity, and the latter to Pacific coast ports. The meal is used principally in California and Hawaii.

NOTES ON BOOKS.

COTTON IN BRITISH WEST AFRICA. By N. M. Penzer, B.A., F.R.G.S., F.G.S. With an introduction by the Right Hon. the Viscount Milner, G.C.B., G.C.M.G. London: The Federation of British Industries. 5*s.* net.

The necessity for increasing the supply of cotton grown within the Empire is being recognised more clearly every day. America is using up her own crops at a rate that increases year by year, and Lancashire will have to look to all possible sources to secure the immense supplies that she needs. Comparatively little is known about West African cotton, and consequently this book, which contains, in a handy and comprehensive form, a great deal of information, should be of special interest to the cotton industry generally.

Section I. is devoted to a short historical sketch in which the industry is traced from earliest records up to date. Section II. deals with Nigeria. After a few general remarks, the methods of cultivation and varieties of cotton are described, with additional notes on the local industry, transport, and diseases and pests. The other British Colonies (Gold Coast, Sierra Leone, and Gambia), are treated in Section III. The cotton-growing in these colonies is, however, now reduced to a local industry. Section IV. describes cotton-growing in Togoland and the Cameroons, giving general and historical details, varieties of cotton, and statistics where available. Section V. deals with the Lake Chad District, chiefly from a point of view of the possibility of its development as a cotton-growing district. Section VI. is devoted to the future of cotton-growing in British East Africa, special emphasis being laid on the necessity for the further development of roads, railways, and agricultural departments.

General statistics and a bibliography complete the volume. The latter embraces the period between 1881 and 1920. It is arranged chronologically, and besides containing books on cotton-growing, has several references to works on spinning, weaving, etc.

THE TIMBER MERCHANT'S HANDBOOK. By Frank Tiffany. London: William Rider & Son, Ltd. 5*s.* net.

The first nine chapters of this book deal with the measures of timbers. In almost every trade there are confusing varieties of measures: for instance, a quarter of linseed from India, if Bombay shipped, is 416 lb.; if Calcutta shipped, is 410 lb.; if bought in Mark Lane, it is 496 lb., but if bought in cargo it is 492 lb. Wheat, again, is sold in Cambridge by the coomb, in Newcastle by the boll, in Doncaster by the load. Plums are sold in Worcestershire by the "pot" of 72 lb., in Middlesex and Kent by the half bushel, which is sometimes 28 lb. and sometimes 24 lb. In the case of apples one is supposed to get 40 lb. to the bushel, but with some kinds one gets more and with others less. One might multiply instances *ad nauseam*, but surely nowhere are the measures more confusing than in the timber trade. In softwoods we have the Petrograd Standard, which equals 165 cubic ft.; the Wyburg Standard of 180 cubic ft.; the Drontheim Standard of 198 cubic ft.; the Christiania Standard of 103⅛ cubic ft.; the Drammen Standard of 121½ cubic ft.; the London and Irish Standards of 270 cubic ft.; the Quebec Standard of 229⅙ cubic ft.; and the Riga Last of 80 cubic ft. Similar complications run through all the timber measures, and the novice will find in Mr. Tiffany's handbook a valuable clue to guide him through the labyrinth which without it must at first seem absolutely paralysing.

Part II. deals with the various kinds of woods; and here the author puts in a plea for precision of nomenclature. There is almost as great confusion in this respect as in the various systems of measures, and Mr. Tiffany refers to a Professor of Botany who includes as "Mahogany" the following woods: African Walnut, African Cedar, *Pterocarpus indicus*, Red Serayah, Camphor Wood, Teak and Sabicu. It is greatly to be regretted that the trade has not yet been able to secure greater precision in the nomenclature of timbers.

The handbook is full of information, and should prove useful to all engaged in the timber industry and its allied trades.

GENERAL NOTES.

BRITISH COTTON-GROWING.—In the House of Commons, on February 23rd, the Under-Secretary of State for the Colonies was asked if the British Empire only grows 24 per cent. of the total cotton of the world, and if he would give the percentage of the cotton now grown in British Colonies, and indicate its gradual growth since 1910, also stating what special steps are being taken to increase cultivation to the fullest extent. The reply was as follows: The figure of 24 per cent. is for the whole Empire, including India, Egypt, and the Sudan. The percentage for the Colonies and Protectorates with which the Colonial Office is responsible is about one-quarter of 1 per cent. Apart from the small but valuable West Indian crop the production is almost entirely in tropical Africa. The figures range from about 38,000 bales of 400 lb. in 1910 to 75,000 bales in 1914 and 47,000 bales in 1918. The recent falling off is largely due to the decreased output of Uganda during the war period, but a greatly increased Uganda crop is now expected. These figures do not include the large amount of cotton grown in Nigeria for the local market, which does not pass through European hands. The possibilities of increased production will in certain cases be limited by the competition of other crops or the sparseness of the local population, but every effort is made to encourage cotton-growing, and special attention has been given to the improvement of Colonial Agricultural Departments. The Colonial Office is in close touch with the Empire Cotton Growing Committee.

British Industries Fairs.—Exhibitions in connection with the fifth British Industries Fair were opened at the Crystal Palace and in Glasgow and Birmingham on February 23rd. The classes of goods on view at the Crystal Palace, where the stalls extend to five miles and cover an area of twenty acres, include cutlery, silver and electro-plate, jewellery, clocks and watches, glassware, china, earthenware, paper, stationery, printing, fancy leather goods, brushes, toys, sports goods, scientific instruments, optical and photographic goods, drugs and druggists' sundries, musical instruments, furniture, and art needlework requisites. The exhibits in Birmingham consist largely of machinery, metalware, hardware goods, and household utensils. Features at Glasgow are clothing, general textiles, foodstuffs, and chemicals. Admission is restricted to business men, of whom 150,000 were invited. The *Board of Trade Journal* mentions that the Fair has been well attended from the opening, not only by British trade buyers but by overseas representatives, including buyers from South Africa, Netherland East Indies, the United States, Finland, and on behalf of the Esthonian Government, as well as from European allied and neutral countries. It is announced that four travelling exhibitions of British goods are to be established for the Overseas Dominions, the Far East, the United States and South America. In addition, the opening of showrooms on the Continent and elsewhere for the display of British productions is under consideration by the Government.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday afternoons, at 4.30 p.m. :—

March 10.—H. M. Thornton, "Gas in relation to Industrial Production and National Economy." Sir Robert A. Hadfield, Bt., D.Sc., F.R.S., will preside.

March 17. — William Worby Beaumont, M.Inst.C.E., "Street Passenger Transport of London." Kennedy Jones, M.P., Chairman, Select Committee on Transport (Metropolitan Area), will preside.

March 24.—L. Gaster, "Industrial Lighting in its relation to Efficiency."

April 14.—Joseph Thorp, "The Fundamental Basis of Good Printing."

April 21.—Air-Commodore Edward Maitland, C.M.G., D.S.O., A.F.C., "The Commercial Future of Airships."

April 28.—Charles H. Sherrill, "Stained Glass."

May 5.—Dr. C. E. Kenneth Mees, "A Photographic Research Laboratory." Sir Henry Trueman Wood, Chairman of the Council, will preside.

Indian Section.

Friday afternoon, at 4.30 p.m. :—

March 19.—Sir William S. Meyer, G.C.I.E. K.C.S.I., Financial Member of Council of the Governor-General of India, 1913-18, "The Indian Currency System and its Developments." The Right Hon. Lord Chalmers, G.C.B., LL.D., will preside.

Thursday afternoons, at 4.30 p.m. :—

April 15.—Brigadier-General Lord Montagu of Beaulieu, C.S.I., "Roads and Transport in India."

May 20.—Sir George Cunningham Buchanan, K.C.I.E., M.Inst.C.E., "The Ports of India: their Administration and Development."

Monday afternoon, at 4.30 p.m. :—

May 31. — Albert Howard, C.I.E., M.A., A.R.C.S., F.L.S., Imperial Economic Botanist to the Government of India, "The Improvement of Crop Production in India."

Date to be hereafter announced :—

Sir Valentine Chirol, "The Enduring Power of Hinduism." (Sir George Birdwood Memorial Lecture.)

Colonial Section.

Tuesday afternoon, at 4.30 p.m. :—

May 4.—Professor William A. Bone, D.Sc., Ph.D., F.R.S., "Lignite."

Indian and Colonial Sections.
(Joint Meeting.)

Friday afternoon, at 4.30 p.m. :—

June 4. — Professor Sir John Cadman, K.C.M.G., D.Sc., F.G.S., M.Inst.C.E., "The Oil Resources of the British Empire."

Dates to be hereafter announced :—

Graily Hewitt, "Rolls of Honour."

Charles Crowther, "The Arts and Crafts of Japan" (with examples from the author's private collection).

William Cramp, D.Sc., M.I.E.E., "Pneumatic Conveying Plants, with special reference to the Transport of Grain."

Cantor Lectures.

Monday evenings, at 8 p.m. :—

Walter Rosenhain, B.A., D.Sc., F.R.S., Superintendent, Department of Metallurgy and Metallurgical Chemistry, National Physical Laboratory, "Aluminium and its Alloys." Three Lectures.

April 12, 19, 26.

Arthur Thomas Bolton, F.R.I.B.A., F.S.A., Curator, Soane Museum, "The Decoration and Architecture of Robert Adam and Sir John Soane, 1758–1837." Three Lectures.

May 3, 10, 17.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MARCH 8...Chadwick Public Lectures, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5 p.m. General Sir John Goodwin, "Military Hygiene in Peace and War." (Lecture I.)

Royal Institution, Albemarle-street, W., 3 p.m. Sir John Cadman, "Modern Developments of the Miners' Safety Lamp."

Mechanical Engineers, Institution of, Storey's-gate, S.W., 8 p.m. (Graduates' Meeting.) Mr. T. F. Davey, "British Association Threads."

Geographical Society, Kensington-gore, W., 5 p.m.

TUESDAY, MARCH 9...University of London, at the School of Oriental Studies, Finsbury-circus, E.C., 5 p.m. Mr. A. D. Innes, "The Mogul Period in the History of India." (Lecture V.)

Metals, Institute of (Local Section), Chamber of Commerce Buildings, New-street, Birmingham, 7.30 p.m. Mr. O. W. Ellis, "The Amorphous Phase Theory and its Applications."

Royal Institution, Albemarle-street, W., 3 p.m. Professor A. Keith, "British Ethnology: the Invaders of England." (Lecture II.)

Civil Engineers, Institution of, Great George-street, S.W., 5.30 p.m. Major-General Sir G. M. Heath, "Royal Engineer Work in the Great War."

British Decorators, Institute of, Painters' Hall, Little Trinity-lane, E.C., 7.30 p.m. Mr. W. J. Pearce, "The Selection and Purposes of Colour in Decorative Work."

Photographic Society, 35, Russell-square, W.C., 7 p.m. Mr. G. I. Higson, "Photomicrography in Photographic Research."

Colonial Institute, Central Hall, Westminster, S.W., 8 p.m. Mr. A. O. Neville, "Through the North-West of Australia."

Horticultural Society, Vincent-square, Westminster, S.W., 3 p.m. Mr. J. Hudson, "Fruits which can be grown under Glass without Fire Heat."

Physicians, Royal College of, Pall-mall East, S.W., 5 p.m. Dr. J. L. Birley, "The Principles of Medical Science as applied to Military Aviation." (Lecture I.)

WEDNESDAY, MARCH 10...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Mr. H. M. Thornton, "Gas in Relation to Industrial Production and National Economy."

Royal Institution, Albemarle-street, W., 3 p.m. Sir John Cadman, "Petroleum and the War."

Geological Society, Burlington House, W., 5.30 p.m.

Industrial League and Council, Carpenters' Hall, Throgmorton-avenue, E.C., 5.15 p.m. Mr. G. J. Wardle, "Industrial Unrest and Whitley Councils."
Central Hall, Westminster, S.W., 7.30 p.m. Mr. E. J. P. Benn, "Should Wages be Lowered?"

United Service Institution, Whitehall, S.W., 3 p.m. Captain P. Worthington, "The Work of the Kite Balloon on Land and Sea."

THURSDAY, MARCH 11 ... Metals, Institute of, at the Institution of Mechanical Engineers, Storey's-gate, S.W., 4 p.m. Annual General Meeting.
8 p.m. 1. Messrs. G. D. Bengough, R. M. Jones, and Ruth Pirret, "Fifth Report to the Corrosion Research Committee." 2. Messrs. R. Seligman and P. Williams, "The Action on Aluminium of Hard Industrial Waters."

Royal Society, Burlington House, W., 4.30 p.m.

Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Child Study Society, at the Royal Sanitary Institute, 90, Buckingham Palace-road, S.W., 6 p.m. Miss M. J. Reaney, "The Educational Needs of Adolescence."

Dyers and Colourists, Society of, Bradford. Mr. G. G. Hopkinson, "Dyeing of Fast Colours on Cotton."

Royal Institution, Albemarle-street, W., 3 p.m. Colonel E. Gold, "The Upper Air."

Electrical Engineers, Institution of, at the Institution of Civil Engineers, Great George-street, S.W., 6 p.m. 1. Mr. W. H. Patchell, "Notes on Operating a By-product Producer Gas Plant for Power and Heating." 2. Mr. S. H. Fowles, "Production of Power from Blast Furnace Gas."

Historical Society, 22, Russell-square, W.C., 5 p.m. Paper on "Some British and Allied Archives in War Time. II.—British Dominions and Crown Colonies Overseas; France; Belgium; Balkan States."

Physicians, Royal College of, Pall-mall East, S.W., 5 p.m. Dr. J. L. Birley, "The Principles of Medical Science as Applied to Military Aviation." (Lecture II.)

FRIDAY, MARCH 12...London Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. The Earl of Lytton, "Inns and Taverns of London—their better adaptation to the Public Need."

Royal Institution, Albemarle-street, W., 9 p.m. Mr. W. W. R. Ball, "String Figures."

Auctioneers and Estate Agents, Institute of, 34, Russell-square, W.C., 7.45 p.m. Sir William Wells, "Professional Education."

Malacological Society, Burlington House, W., 8 p.m.

University of London, University College, Gower-street, W.C., 5 p.m. Dr. T. Borenius, "Mediæval Art." (Lecture IX.)

Astronomical Society, Burlington House, W., 5 p.m.

Metals, Institute of, at the Institution of Mechanical Engineers, Storey's-gate, S.W., 10.30 a.m. 1. Mr. J. N. MacLean, "The Art of Casting in High Tensile Brass." 2. Messrs. H. Moore and S. Beckinsale, "The Removal of Internal Stress in 70 : 30 Brass by Low Temperature Annealing." 3. Dr. W. Rosenhain, Mr. J. L. Haughton, and Miss K. Bingham, "Zinc Alloys with Aluminium and Copper." 4. Dr. W. Rosenhain, "A Model for representing the Constitution of Ternary Alloys." 5. Mr. A. C. Vivian, "Tin-Phosphorus Alloys." 6. Messrs. W. C. Hothersall and E. L. Rhead, "Some Notes on the Effect of Hydrogen on Copper."

2.30 p.m. 1. Mr. W. E. Alkins, "The Effect of Progressive Drawing upon some Physical Properties of Commercially Pure Copper." 2. Mr. F. Johnson, "The Influence of Cold Rolling on the Physical Properties of Copper." 3. Mr. J. L. Haughton, "The Study of Thermal Electro-Motive Force as an aid to the Investigation of the Constitution of Alloy Systems." 4. Mr. H. H. Hayes, "Note on the Polishing and Etching of Zinc for Micro-Examination." 5. Mr. W. E. Hughes, "Idiomorphic Crystals of Electro-Deposited Copper."

Physical Society, Imperial College of Science, South Kensington, S.W., 5 p.m.

SATURDAY, MARCH 13...Royal Institution, Albemarle-street, W., 3 p.m. Professor Sir J. J. Thomson, "Positive Rays." (Lecture IV.)

Journal of the Royal Society of Arts.

No. 3,512. VOL. LXVIII.

FRIDAY, MARCH 12, 1920.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

WEDNESDAY, MARCH 17th, at 4.30 p.m. (Ordinary Meeting.) WILLIAM WORBY BEAUMONT, M.Inst.C.E., "Street Passenger Transport of London." KENNEDY JONES, M.P., Chairman, Select Committee on Transport (Metropolitan Area), will preside.

FRIDAY, MARCH 19th, at 4.30 p.m. (Indian Section.) SIR WILLIAM S. MEYER, G.C.I.E., K.C.S.I., Financial Member of Council of the Governor-General of India, 1913-18, "The Indian Currency System and its Developments." THE RIGHT HON. LORD CHALMERS, G.C.B., LL.D., will preside.

Further particulars of the Society's meetings will be found at the end of this number.

THIRTEENTH ORDINARY MEETING.

WEDNESDAY, MARCH 10th; SIR ROBERT A. HADFIELD, Bt., D.Sc., D.Met., F.R.S., Vice-President of the Society, in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Bond, Colonel Charles John, C.M.G., F.R.C.S., Leicester.

Gane, Charles, London.

Kahn, Otto H., New York City, U.S.A.

Kerfoot, Thomas, Gee Cross, Cheshire.

Murray, Victor F., B.Sc., London.

Pullin, Victor Edward, London.

Rawson, Thomas Gregory, Borrowash, Derby.

Reed, Clifford, Nelson, Lancashire.

Robarts, Harvey B., M.A., F.R.G.S., London.

Roberts, Joseph Henry, Rotherham, Yorks.

Tagore, Raj Kumar Nawab S. K., Calcutta, India.

The following candidates were balloted for and duly elected Fellows of the Society:—

Aiyar, S. Paramesvara, M.A., B.L., Travancore, South India.

Cantrell, T. B., Liverpool.

Gurtu, Pundit Sri Krishen, M.A., M.Inst.C.E., Morar, Central India.

Healey, William, B.Sc., Assoc.M.Inst.C.E., Assoc.M.I.Mech.E., London.

Knox, George, F.G.S., Cardiff.

Walker, Frederick H., B.Sc., A.I.C., Newcastle-on-Tyne.

A paper on "Gas in Relation to Industrial Production and National Economy" was read by Mr. H. M. THORNTON, J.P., Assoc.Inst.C.E.

The paper and discussion will be published in a subsequent number of the *Journal.*

THE ALBERT MEDAL.

The Council will proceed to consider the award of the Albert Medal of the Royal Society of Arts for 1920 early in May next, and they therefore invite Fellows of the Society to forward to the Secretary on or before Saturday, March 27th, the names of such men of high distinction as they may think worthy of this honour. The medal was struck to reward "distinguished merit in promoting Arts, Manufactures, and Commerce."

The list of those who have received the medal since its institution in 1864 was printed in the last number of the *Journal.*

COVERS FOR JOURNALS.

For the convenience of Fellows wishing to bind their volumes of the *Journal*, cloth covers can be supplied, post free, for 2*s.* each, on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

NINTH ORDINARY MEETING.

WEDNESDAY, FEBRUARY 11th; REAR-ADMIRAL SIR DOUGLAS EGREMONT R. BROWNRIGG, Bt. C.B., Chief Censor, Admiralty, 1914-18, in the chair.

The paper read was --

THE DAZZLE PAINTING OF SHIPS.

By LIEUT.-COMMANDER NORMAN WILKINSON, R.N.V.R., O.B.E., R.O.I., R.I.

The paper I am about to read to you deals with the origin and development of dazzle painting, and I shall endeavour to show the reasons for its adoption, as opposed to painting a ship with a view to achieving invisibility. At first sight it would appear that the latter was the sound line to take when seeking to render a ship immune from submarine attack, but on examination I think I can show you the fallacy of painting a vessel in this manner.

Dazzle painting is a method to produce an effect (by paint) in such a way that all accepted forms of a ship are broken up by masses of strongly contrasted colour, consequently making it a matter of difficulty for a submarine to decide on the exact course of the vessel to be attacked.

I shall hope to show you that so-called invisibility against submarine attack is not only impossible, but dangerous, and consequently, if a vessel can be seen at all, it does not matter how visible she is, providing her course remains a matter of question to the attacker. The accurate determination of a vessel's course is the prime factor required by a submarine commander to ensure successful attack.

Many animals and birds are provided by Nature with an external scheme of colouring which harmonises with their surroundings in such a way as to make them practically invisible to an enemy, so long as they are in a state of rest. This applies also to a number of animals more or less immune from attack, and is provided in order that they may lie in wait for unsuspecting prey.

All the previous attempts which had been made to utilise paint as a defensive measure, when dealing with ships, were with a view to rendering them invisible.

Land camouflage, as practised in the theatres of war, has developed along the lines of protective colouring or invisibility, and has reached a remarkable pitch of perfection. It is not difficult to see the reason for this. When desirous of hiding any particular object, such as a battery of guns from the enemy, you are more or less assured of surroundings of a broken nature, little likely to be subject to a change of colour, and, providing you can successfully imitate these surroundings, by covering your battery with fabric, etc., you have practically achieved your end. There is, of course, a highly technical side to this work, and some of our most skilled artists have been working on the problems presented throughout the war; but these I will not go into now, as they have little or no bearing on the special form of camouflage I am about to deal with.

If we turn again to sea camouflage, *i.e.* the painting of ships as a defensive measure, we find an entirely different order of things. Firstly, the ship is in motion. Secondly, you have two elements, sea and sky, subjected to constant changes of colour and light. Thirdly, there is the horizon, a most difficult problem to deal with, which is either a hard clear-cut edge against a brilliant sky, or elusive and blurred. Conditions vary greatly according to the particular part of the globe under survey.

Let us take two localities characteristic of these conditions, and also as being the great hunting grounds of the enemy submarine during the war, viz., the Mediterranean and the coast of Great Britain. You find, generally speaking, the weather conditions in the first named are: Clear sky, dark sea, with sharply defined horizon; while round the British coast you get a softer horizon, and less contrast between sea and sky, due to moisture in the atmosphere and other local conditions. I speak with some experience, having been a marine painter with long experience at sea, and constant observation of weather, colour, etc. Now it will be at once apparent that a ship painted with a view to obtaining invisibility in one locality has very little chance of being successful in the other, and having once been seen by a submarine, from that moment loses any defensive qualities paint can give her.

Let us suppose you are setting out to paint a ship in order to bring about invisibility. You first of all require her hull to be in a fairly clean condition, as you are intending to paint her in very light delicate shades of colour. Assuming the very unlikely case of getting your vessel in this condition, you commence work. On the second day, when you are well on with your painting, a coal lighter comes alongside, and as the life of the country is dependent on the ship getting to sea, you cannot stop this operation. Therefore, your clean paint has a film of coal dust of varying intensity all over it. She has then to take in or discharge cargo, with its consequent wear and tear of paint, warps or tenders are rubbing her sides, scupper pipes and endless exhausts trickle down her sides, which makes it impossible to paint here at all. However, having got over these difficulties as best

you can, she goes to sea. Now comes a further trial, her hawse pipes run streaks of rust down either bow, and her water-line becomes rusty or is coated with oil deposit from her stay in port, and finally you cannot expect her short-handed crew to devote hours of their time to constantly re-painting her to your exact shades of subtle colours. Assuming, however, that you do get her to sea in perfect condition as regards paint, can you make her smoke invisible? With a following wind, this smoke will ascend hundreds of feet into the air, quite possibly at a time when a watchful submarine is looking out for prey; he does not need to look for your invisible ship, he knows she is there and has an easy job.

All these difficulties were practically non-existent with the dazzled ship, the requirements in her case were strong contrasts of colour, and even though your light colours were dirty the juxtaposition of black made them appear clean by comparison. I have seen an old tramp steamer in the London Docks, which had not had a touch of new paint on her dazzle scheme for five months, and the effect of the distortion was perfectly good. Had she been painted for invisibility scarcely anything would have remained of her scheme, and the most pronounced optimist could not have claimed that she suggested anything of an invisible nature. It always struck me that the dazzled ships seemed cleaner than an "all one coloured" ship, on the principle that a white table-cloth will look dirty sooner than a patchwork quilt.

It appears to me that one reason for the continued attempts to obtain invisibility at sea has been largely contributed to by the fact that vessels are nearly always seen from the bridge or look-out of another vessel, or from a shore station, all of which vantage points are a considerable height above the sea-level, thus giving the observer a sea background of a fairly dark tone. Now the submarine commander's point of view is entirely different. He sees every ship against a sky background only, with practically no foreground of water, which is a very different proposition.

A ship seen from another vessel's bridge may, under certain weather conditions, achieve a partial degree of invisibility when the colour of the ship's hull and the sea happen to coincide. But this same ship, seen at the same time by a submarine, will appear as a darkish silhou tte against the sky.

This partial invisibility will only be gained in small vessels of the cargo type, where there are no promenade or hurricane decks, or other structures liable to cast shadows.

At the commencement of the scheme I was frequently told that invisibility could be gained by the application of Thayer's law of shadow elimination, and that if you painted the undersides of a passenger deck white, you can overcome these deep shadows. This I can definitely state to be a fallacy. No paint which is in itself dependent on the sky for light can overcome a shadow of this density. There is one instance where white paint can be utilised to overcome shadow, and is sometimes very useful. This is on a vessel with a marked flare to the bow, by painting the upper portion of the hull with white and the lower part a grey or blue, the appearance of the flare can be largely neutralised, and will often tend to alter the character of the vessel in a marked way by flattening the bow. The reason for the success of this measure is owing to the strong reflected light cast upwards on to the flare of the bow, and consequent illumination of the white paint. This applies more forcibly when the vessel is under weigh.

An important argument against invisibility at sea is the smoke. Where there is an unlimited supply of hard coal, or the vessel is oil burning, you may overcome this difficulty to a certain extent, but there will be times when any vessel will show smoke, so that even if it were possible to achieve complete invisibility of hull, it might be at that moment that her position would be disclosed to an enemy submarine on the look-out. I suggested to the Admiralty, in the early stages of dazzle painting, that the question of a vessel's smoke should be gone into, with a view of obtaining a really efficient smoke destructor, such as you have in a shore factory, in that it would prevent a vessel, hull down, from being observed. Where you have a ship with a following wind, burning soft coal, her smoke will ascend vertically and make her presence known at a great distance. Two further strong arguments against obtaining invisibility are the bow wave and the stern wash, both of which I saw no way of overcoming.

I have attempted to give you one or two reasons showing why, in my opinion, any attempt to gain invisibility of a ship at sea by means of paint is bound to fail. There remains, however, one more factor, which I think finally disposes of the last vestige of chance in this direction. This is the director hydrophone. This instrument puts the vessel painted for invisibility more or

less in the position of the ostrich. We know the Germans had developed the hydrophone to a high state of efficiency, and were able, by its use, to decide not only on the probable class of a single ship, or a number of ships roughly, if in convoy, but could, by a series of listening observations, obtain the general direction in which the ship or convoy was proceeding. This is naturally only approximate, but will be of considerable help in the very early stages of the attack. After deciding on the direction, the submarine will rise and commence visual work with the periscope, and it is from this moment that the ship painted all one light colour, or in a series of small spots or parti-coloured paint, becomes a comparatively easy prey; and although she may be zigzagging her course can be determined far more easily than a vessel painted in the way I shall describe. This determination, of course, is the prime factor required by a submarine when making an attack.

It was from the moment that I realised the hopelessness of obtaining invisibility that it seemed to me something could be done with paint on entirely different lines. At the time my proposal was put forward, all transports were painted black from waterline to truck. I was continually on patrol in the Channel in May 1917, and it struck me that of all the colours that could have been chosen, this was the most dangerous. A submarine commander, had he been given the choice of colours to ensure successful attack, would most certainly have decided on black, both for day or night. My reason for relying on paint was the knowledge that the employment of fabrics, such as netting, gauze, or the numerous other articles used in land camouflage were impracticable. Endless propositions of this nature were put forward by people interested in the question of invisibility, but in nearly every case those making them have little experience of the sea and its ways, and do not realise its power.

Another factor not remembered by many, even when experienced, is the human element. The sailor is temperamentally conservative. You may rig endless devices in harbour, and make your ships as invisible as you can, but twenty-four hours out of harbour they may be swept by a gale, or even a strong breeze suffices, and what remains of your canvas strips and muslin trimmings? Not a shred! Does your sailor, believing in your schemes, painstakingly re-rig your pet devices? If I know anything of him, he does not. If he is sunk, he is sunk; but he will not put in half his watch below replacing your fancy fittings. It will be seen, therefore, that paint was the only practical means of disguise which could be applied to the hull of a vessel in such times of stress.

There are, of course, certain important and simple structural additions of a permanent nature which can be made, if time permits, to increase the difficulties of an attacking submarine, but these I will touch on later.

It was the knowledge that the all-important factor to a submarine commander was the determination of a ship's course which gave me the idea that, if the accepted form of a vessel could be so completely broken up by contrasting colours and tones of paint as to destroy her outline and general shape, a large point would have been gained towards increasing the difficulties of attack.

The primary object of this scheme was not so much to cause the enemy to miss his shot when actually in firing position (although this has happened in a number of cases), but to mislead him, when the ship was first sighted, as to the correct position to take up.

With a vessel of ten knots or over, a submarine, having once failed to obtain a good position, has little or no likelihood of regaining that position, owing to insufficient underwater speed. Should he decide to come up and overtake the ship by surface speed, the ship attacked, being armed, has every chance of a successful escape, and I should consider it a great testimonial to the painting that it had brought the enemy to the surface.

In submitting this scheme to the Admiralty, I made no claim that a ship so painted was certain of escape, but simply that she must present a more difficult proposition to a submarine, and could not be easier than an "all grey ship." Another point was, that it meant little or no delay to the vessel, as every ship must be painted for weather protection. The fact that nothing of a structural alteration was required was important, and, finally, the cost was negligible, as upwards of one hundred vessels could be painted for the cost of one good class cargo boat and cargo.

The Admiralty immediately placed a vessel at my disposal for the purpose of experiment. This particular ship, H.M.S. "Industry," was employed on a regular run between Plymouth, Portsmouth, Pembroke, Chatham, and Queenstown, and therefore constantly in the danger zone. She was painted to a design I had prepared and completed in three days whilst loading, and sailed to schedule time.

Orders were meanwhile issued to all navy vessels and shore stations to report on her appearance, when met with; but, knowing the length of time these reports would take to filter through, and also that this first design could not be all I wished, I approached the Admiralty for a larger development of the scheme at once in order to get more frequent reports. Within a day or two fifty transports were ordered to be painted as rapidly as opportunity offered. Each of these vessels was painted differently in order to prevent the enemy from becoming accustomed to any particular design. Some designs were, of course, more successful than others, and I eliminated those which were reported on as not giving the required distortion. Some time before the end of the war we had arrived at the most successful type of design, namely, striped designs. These were commented on by a great number of seamen as being by far the best for upsetting the calculation of a ship's course. These stripe designs not only succeeded in breaking up the above-water structures of a vessel very successfully, but they also had the advantage of being practically fool-proof in application—a most important point. In the early stages of the scheme, before we were able to collect and train a staff of outport officers, we had considerable difficulty in getting the designs intelligently applied, as it largely depended on the personality of the particular foreman in charge of a job whether the design was a success or not. But I found that these foremen painters became highly interested in the work as soon as they thoroughly understood its meaning, and later were of the greatest assistance in carrying through the scheme. I attribute this very largely to the fact that, as far as my observation goes, every foreman painter has a feeling deep down that he is by instinct an artist who happens to be dealing with art in a broader sense than the ordinary picture painter. This, at least, has been borne in on me by confidences I have received during visits to ships in the course of painting.

The method of procedure by which the ships became painted will probably interest you.

In the initial stages a small model in wood was made to scale of each ship, on this a design was painted in wash colours for the purposes of rapid alteration. This model was then carefully studied on a prepared theatre through a submarine periscope, various sky backgrounds being placed behind her alternately. A satisfactory design having been evolved, giving the maximum distortion, the model was then handed to a trained plan maker and copied on to a 16th-inch scale profile plan of the ship on white paper, showing port and starboard side. The plan was then sent to the outport officer at the port at which the particular ship was lying, and transferred under his supervision to the ship. With the extension of the scheme to the whole mercantile marine, it became impossible to make a model and plan for every ship, and I determined to divide the mercantile marine into typical classes of vessels. For each type of ship a number of designs was made, according to the demand for the particular class, and each outport officer was kept supplied with all designs, so that on the arrival of a ship requiring a plan he was able to select one which fitted her as nearly as possible. This scheme worked wonderfully well, but needed a great deal of skilled supervision in the early stages, as, with a ship, say, 350 ft. long and a plan of 380 ft., it could not be left to a foreman painter to deal with. When the scheme had been in operation for some time, many of these foremen became so interested and keen that we were able to leave the adaptation of a plan to a ship of different length to them—in a number of cases with conspicuous success. These men were a great help, as the bulk of work grew enormously, and we sometimes had as many as one hundred vessels painting at a time in one port, with only two or three officers to attend to the lot with long distances to cover.

At first, although explained in the Admiralty Memorandum, some confusion still existed amongst seamen as to the object of dazzle painting, and a certain number of reports showed that it was thought invisibility was still being aimed at. However, when better understood, almost every report showed that the new scheme of painting was accepted as an effective contrivance in assisting to combat the submarine. From a large number of reports it could be seen that the idea of making the course difficult to determine had been thoroughly grasped. I will read you one or two of these, as illustrating the way in which the new form of painting was received.

H.M.S. "Martin,"

September 27th, 1917.

"Sighted oiler 'Clam' about six miles, four points on starboard bow, and for some time could make nothing of her. When about four miles distant, I decided it was a tug towing a lighter with a short drift of tow rope. The lighter, towing badly and working to the

windward, appeared to be steering an opposite course.

"It was not until she was within half a mile that I could make out she was one ship steering a course at right angles, crossing from starboard to port. The dark painted stripes on her after part made her stern appear her bow, and a broad cut of green paint amidships look like a patch of water. The weather was bright and visibility good. This was the best camouflage I have ever seen."

REPORT ON H.M.S. "EBRO" FROM H.M.S. "SAYONARA."

October 1st, 1917.

"September 25th, 9.55 a.m., sighted H.M.S. 'Ebro' in the Sound of Mull on the port bow, end on.

"She appeared to alter course to port immediately after, and seemed to continue to do so, whereas, in reality, she was altering her course to starboard.

"I should think confusion would be caused in aiming gun or torpedo.

"I was so sure that she was trying to cross my bows that I was on the point of stopping my engines and going full speed astern to avoid a collision, when I discovered that she was altering course to starboard. After passing the vessel it was almost impossible to say how she was steering."

H.M.S. "MISCHIEF,"

October 18th, 1917.

"Sir,—I desire to bring to your notice the following facts :—

"At about 9.30 a.m. on Wednesday, October 17th, whilst proceeding up the Firth of Clyde in H.M.S. 'Mischief,' I observed a convoy of some eight ships, oilers, etc., proceeding to sea in a single line ahead.

"No. 6 in the line was 'dazzle painted,' and appeared to me to be steering at least eight points different to the other ships in the line. So remarkable was this optical illusion that I sent for all my officers and asked their opinion as to the course of the ship. Not one officer agreed within four points. This optical illusion remained until the ship in question was past our beam, when it was seen that she was steering the same course as the others.—I have the honour to be, etc.

"(Signed) CYRIL WARD, Commander."

S.N.O. "ARDROSSAN,"

September 25th, 1917.

"*Vessels unknown.*—In all cases, more especially when viewed at a distance of about three miles, the vessels presented an appearance of being grotesquely out of all proportion; infinitely more so when the sun shone directly upon them. When approaching, it was not until the vessels were quite near that it was possible to see their bows, even when quite close; at about half a mile the bows seemed to be directly under the bridge. The deception as to distance between bow and bridge, which in all cases appeared extremely high, was indeed remarkable."

OFF SOUTH ROCK LIGHTSHIP,

October 6th, 1917.

"'*Clam.*'—Effect of camouflage painting was that the vessel, at a distance of about two to three miles, appeared as a wreck on her beam ends, and patches of paint on bows caused absence of perspective. It was difficult to locate the vessel's stern. This was increased by the fact that she had only one thin, short mast placed well abaft the centre of the ship."

H.M.T. "ANZAC,"

August 15th, 1917.

"'*Ocean Monarch.*'—(*a*) No apparent difference was noticed in speed, but the course she was steering was particularly deceptive. At times, principally when viewed from ahead, she appeared to be steering as much as six points to port of her actual course; my attention being called by my second hand on two occasions when he thought this was actually taking place.

"(*b*) It was difficult to tell what type of ship she was. At times she appeared to be only half a ship, *i.e.* a vessel with her bow and stern cut off.

"(*c*) When I was right ahead of her, and she was heading directly towards me, sun right head of her as before, she appeared to be heading six points off her course to port."

CAPTAIN BARTTELOT,

September 25th, 1917.

"*S.S.* '*Millais.*'—Convoy was observed by three destroyer officers running trials at distances varying from two to four miles.

All three officers agree that the 'dazzle painting' of the 'Millais' was a huge success. They state that it was quite impossible to state her course even approximately, except when the sun lit up her masts. Lieut.-Commander Harrison stated he could not tell her course within twelve points."

13 O.B. CONVOY SECTION.

"*H.M.S.* '*Mantua.*'—The dazzle scheme on the starboard side of 'Ascanius' is excellent. The ship sometimes appears to be going in the

opposite direction, and in misty weather her course cannot be judged within eight points.

"On a bright moonlight light she was invisible at one mile.

"I am strongly of opinion that all ships should be painted on these lines."

As a result of these and a large number of other reports, it was decided by the Admiralty in October, 1917, under the Defence of the Realm Act, to paint the whole British mercantile marine, and a considerable number of war vessels employed on convoy and other duty. I will read you the Admiralty Memorandum on the subject as issued :—

INSTRUCTIONS TO "DAZZLE" OFFICERS.

Confidential Admiralty Interim Order No. 37531/6.

"It has been decided to paint all merchant vessels and armed merchant ships, and certain of H.M. ships, with the 'Dazzle' scheme of painting.

"This scheme is based upon the principle that invisibility at sea being unattainable, some protection may be afforded by painting ships in such a way as to confuse an enemy submarine, and, by causing doubts as to the course, speed and distance, thus delay the discharge of the torpedo and cause uncertainty of aim.

A number of designs are in preparation which will enable a suitable plan to be selected for any particular ship that may come in hand for refit or painting.

"Officers are being selected who will represent the Director of Naval Equipment at all the principal shipping ports, and who will be furnished with plans prepared at the Admiralty."

For a time, in the early stages of the scheme, I hesitated to use white paint for various reasons, but after considerable experience, it was found to be the best "colour" for those parts of the ship intended to be invisible. I will read you a few remarks from one of my officers on white paint :—

REPORT FROM LIEUT. H. A. YOCKNEY, R.N.V.R.,
Belfast,
February 3rd, 1918.

"*Submitted.*—Between January 31st and February 1st, I took the opportunity of proceeding in H.M.Y. 'Albion III.' to view the appearance of the O.B. Convoy No. 44 while at sea. The weather conditions on this occasion were fairly typical of those usually experienced in the North Sea, namely: Wind S.E., force 4 to 6, sea 4, visibility 3–5 miles. My conclusions were as follows :—

"(1) That when white had been used extensively in a dazzle design, by far the best results appear to be obtained.

"(2) That the best dazzled ship in the convoy was the S.S. 'Demosthenes.' The power of hull design chiefly lies in the large amount of white employed on the upper portion of her bows and bridge. From a number of points of view this white portion appeared to be a part of the midship superstructure, producing a very confusing effect, it being quite impossible to make out the ship's course, or to discover the form of the bridge.

"(3) That the design of the port side (I did not see the starboard side) of the S.S. 'Botanist' would have been improved had more white been used on some parts. From the bridge to a point abaft the funnel where white was prominent in juxtaposition to dark colours, a most awkward appearance was produced, but too large a portion of the painting of the hull aft was very weak, which helped to make judgment easier as to course of ship. I believe that some white about this portion would have much improved the design as a whole.

"(4) That the design on the S.S. 'Colonial' was not very effective. The contrasts between the colours used were not nearly intense enough, suggesting the requirement for some white.

"(5) That the stern and outline of stern should be broken up by colours in strongest contrast, always including white. The white as schemed in bows of S.S. 'Demosthenes' supports this view, and the officers of the 'Albion III.' spoke of a dazzled ship they had seen with poop cut off by white. The white, they say, completely destroyed the outline of the stern, and was mainly responsible for their having come to the decision that the ship was the best dazzled one they had seen."

Although I have told you that, from my point of view, it is impossible to obtain invisibility by painting, it is, nevertheless, possible to render parts of a vessel relatively invisible by contrast, and this is a large factor in "dazzle" painting.

The best method for achieving this is by painting your light parts of a design with two light colours, varying definitely in tone. By this I do not mean a blend of two colours in spots or squares, but in definite flat tones of each.

To deal first with the starboard side :—

Divide the vessel amidships; paint the fore end white, and the after end, say, No. 2 blue.

On the port side: Fore end No. 2 blue, and after end white.

This is the broad principle, but is subject to certain modifications. For instance, a colour should never be allowed to stop at an important constructional point, such as the stem or centre of stern; consequently, either the white on starboard side or the blue on port side, should be carried round the bow until checked by part of the dark pattern, and the same at the stern.

The reason for painting the ship in two tones of light colour was that there is a far greater chance of one of them harmonising with the sky behind, and thus giving great distortion to the vessel when used in conjunction with black or dark greys.

It may be said: Why not paint the vessel in a number of sectors of different tones? The reason for not doing so is that you must have large masses of simple colour if you desire to carry long distances. It was found, early in the stages of dazzle painting, that a number of light colours in close juxtaposition, simply meant a great increase in the labour of marking a ship out, and the cost of painting, without achieving any better result than that obtained by two simple masses of light colour.

A number of various light paints on the ship's side after exposure to weather, and the rough handling they are bound to be subject to, become reduced to one light tone of a neutral tint, and are no more effective than giving the parts you require to be light a single colour.

Coaling is only one of the operations which rapidly reduce subleties to nothing, and with the urgency and rapidity with which ships were handled in ports during the war you could not indulge in elaborate schemes of painting requiring constant attention. If you are to deal with large numbers of ships, it is essential that whatever scheme is adopted should be simple of application. I have found that, although the scheme is reduced to the simplest possible method, it requires constant attention and inspection to ensure vessels being painted in keeping with the plans. The simpler your design, the greater degree of distortion you can achieve.

The most important parts of a ship on which to obtain distortion are in the neighbourhood of the stem and the forebridge, both of these are of great use to a submarine in determining the course. Where a ship was being painted against time, these parts were attended to first.

The colours mostly in use were black, white, blue and green, either in their primary condition, or mixed to various tones. When making a design for a vessel, vertical lines were largely avoided. Sloping lines, curves and stripes, are by far the best and give the greatest distortion. The process of marking out a ship was soon learned by the foreman painters under proper supervision. As an instance, the "Leviathan," ex "Vaterland," was marked out in just over two days, and it should be remembered that she is a very extreme type.

The fact that she took a considerable time to paint was due to the number of vessels painting in Liverpool at the time—forty, to be exact—and also to the area requiring paint, which is in the neighbourhood of three acres. The output of dazzled ships was definitely restricted to the supply of skilled painters obtainable, and the quantity of paint available. Warships were dealt with by their own crews.

The American destroyers and patrol vessels in European waters, for which I made upwards of 120 designs, were painted in the majority of cases by their own crews.

Soon after the commencement of unrestricted submarine warfare, I saw a certain number of U.S. merchantmen painted to various ideas, mostly on the lines of invisibility, and I must say it invariably seemed to me a waste of time and paint so to paint them. One I saw in Liverpool was closely covered with very small spots of grey, blue, and pink of a more or less regular pattern. This, at half a mile and upwards, showed as a flat tone of grey, and the long dark promenade decks and other shadow-casting projections would at once locate her to a watchful submarine, even supposing the hydrophone to be non-existent. These schemes were entirely abandoned after my visit to Washington in order to explain dazzle painting.

A certain number of warships were dazzle painted; these were mostly convoying cruisers, destroyers, minelayers, and vessels working with merchant vessels. Two battleships were painted with a view to experiment with range-finders, but I had stated in the early stages of the scheme that I attached no value to dazzle painting as an antidote to gunfire, as no paint has sufficient carrying power to be effective at the long ranges of a modern battle action.

The element of surprise is a big factor, and for this reason designs should be as varied as possible, and always different on both sides of a ship. A submarine sighting a vessel at some distance, would probably make as extended observations as she dared, and, in manœuvring

to get a general view of the ship, would obtain an entirely different impression on crossing her bows. Those extended observations would increase the chances of her being seen by watchful lookouts. I believe there is little doubt that in many cases attacks on dazzle ships have been abandoned by the enemy, without the vessel in danger of attack being aware of the fact, owing to the submarine finding too late that she had taken up a wrong position to ensure a successful shot.

A point of considerable interest, on which I have unfortunately very little information, is the German view of dazzle painting. Naturally, the enemy scoffed at our dazzled ships, and in one case a submarine commander professed to believe we were short of paint. Nevertheless, what came through in the way of evidence is somewhat convincing. The first report received was to the effect that German agents were sketching the designs of our vessels in Norwegian ports, and later that the German Admiralty had dazzle painted a liner, and had attached her to the submarine training depot at Kiel. Finally, a number of the surrendered submarines were painted in precisely the same manner as our merchant vessels, so that it looks as if considerable importance was attached to the training of their officers to the new conditions.

The French, Italian, and U.S. Governments took up the scheme, and a certain number of Japanese ships were about to be painted at the time of the Armistice. I had four French naval officers training in London, and the French Government started an establishment similar to our own, and a large number of designs were made under my supervision. I visited Washington at the request of the U.S. Navy Department, and explained dazzle painting, which was then officially adopted.

There was great keenness on the part of captains of ships for their vessels to be painted. The idea became generally understood, and appreciated by them, for they saw numbers of these ships at sea, and found considerable difficulty in determining the course steered, and realised that if from a bridge, with a clear and unrestricted view, this was true, it must, in the nature of things, be more difficult from a periscope with limited vision and short observation.

All I have said up to the present has dealt exclusively with the uses of paint as an anti-submarine asset, but in addition to this, the above-water structure of a ship can be dealt with in such a way as to make it a matter of considerable difficulty to estimate course, and I will give you a few points which I have actually observed as being the most important.

These are mainly the masts, funnels, bridge and anchors. The old convention of raking the masts and stacks is of the greatest assistance to a submarine when estimating the course of a ship. Where a ship of old design has two or more masts or funnels, this can be overcome to a certain extent by placing them in a vertical position. But by far the best camouflage is the single mast and funnel, in close juxtaposition as in the standard ship.

At the time when the enemy submarines were making a dead set at our oilers, and sinking them in large numbers, it was realised that something structural might be done to increase the difficulties of an accurate estimation of course. With this end in view, it was decided to remove the masts and place the funnel in a vertical position, at the same time a short stump mast was erected about 8 ft. out of the centre line and close to the funnel. I have seen a number of these vessels after this treatment had been carried out, and when combined with dazzle painting it was frequently a matter of considerable difficulty to decide when the vessel was head-on from a comparatively short distance.

The bridge, where, as in the majority of cases, this has a straight foreside, with rectangular ends, is a point much used by submarines for judging inclination. Dazzle painting in a great many cases breaks up a bridge in such a way that the actual angle of the bridge is impossible to determine, but there are conditions of light which no paint will overcome, consequently some structural device would increase the difficulty of an attacking submarine. It has always seemed to me that the best and simplest device is a bridge built on a slight continuous curve with rounded corners, thus doing away with any sharp angles likely to throw definite shadows, and so define the ends.

The bow anchors, where there are hawsepipe anchors, are a great assistance to determination of course. They should be dealt with so as to heave right up into slotted beds, with covering plates, or, failing this, set at different distances from the stem, one being, say, 1, 3, or 4 ft. further aft than the other.

A flush-decked steamer, similar to the Admiralty pattern oilers of the "Leaf" class, is far better than one with well decks.

The more erections you have on a ship's decks the greater chance a submarine has of getting

your course. The wings at the various breaks of a steamer's decks, as in a three-island ship, are bad from an anti-submarine point of view.

I have embodied, as far as possible in this paper the main features of interest as regards dazzle painting; there are, of course, a great many points on which it is only possible to touch lightly, but I hope, from what I have told you, you will have gained a closer view of its objects. As to its practical value in the war, the consensus of opinion is that a large number of vessels were saved by its use.

A number of dazzled ships were, of course, hit by torpedoes, but a far larger percentage of these made port than ships painted light grey, owing to the submarine making an erratic shot and so injuring the vessel in a less vital spot—that is, either right forward or aft. This demonstrates that even when in close contact with the target the commander was still uncertain as to the actual inclination.

Whether paint will ever play any part in future wars it is difficult to say; but, judging by the adaptation of comparatively mediæval weapons to modern conditions on the Western front, I think it would be safe to say that, in what I hope will be the dim future, strange looking craft will once more pursue their apparently erratic courses across the sea.

DISCUSSION.

THE CHAIRMAN (Rear-Admiral Sir Douglas Egremont R. Brownrigg, Bt.) said that he felt it an honour to be asked to preside at the Royal Society of Arts that afternoon. He was also a little puzzled. He did not know whether the subject discussed might not comprehend some of the work with which he himself was concerned during the war. He had further been bewildered by the use of the term "naval camouflage," which was the title of the paper as originally announced. He had turned to a well-worn French dictionary, where the nearest words he could find were *camisole*, *camomille*, and *camouflet*. The meaning of the last of these words was given as "stifler," and he wondered whether the Royal Society of Arts in its wisdom had coupled with this idea of camouflage the sister expression, and expected him that afternoon to fill the *rôle* of "camouflet." He was also interested to see that Lieut.-Commander Wilkinson did not himself use "camouflage" as the title of his paper, but called it "Dazzle Painting." The speaker had visited Lieut.-Commander Wilkinson's school at the Royal Academy in Burlington House, and he wondered whether he got the word "dazzle" from his staff, which consisted of about one hundred and twenty young women, whose looks and dress might have produced an effect of that description. To speak seriously, he was in Scapa Flow on the Good Friday of 1918, and standing in a ship four hundred yards from the "Ramillies" battleship—one of the two battleships which were camouflaged—both he and the other officers could not tell which way the ship was heading.

SIR EUSTACE H. TENNYSON D'EYNCOURT, K.C.B., thought there was no doubt that the work of Lieut.-Commander Wilkinson had had its very marked effect in baffling the German submarine encounters, and even though it might not always have prevented the submarines attacking the ships, he thought it prevented them distinguishing one ship from another in a good many cases. He believed that very often the Germans were particularly told to mark certain ships, and when they saw that the thing looked—as a seaman expressed it to him—"like a cross between a zebra and a sea-serpent going off for the week-end," they were nonplussed. He himself had had to disguise certain ships by making them look like other ships; this he did by altering the superstructures and so on, and he and those working with him had paid attention to such points as Lieut.-Commander Wilkinson had mentioned, confining themselves, for instance, to one mast or one funnel, or, in many cases, rounding the bridges. He was afraid he was not in a position to give actual figures regarding the number of camouflaged ships which passed through the danger zone as compared with the ships not camouflaged. He would hesitate to do so with the Chief Censor present, fearing that that official would transfix him with his blue pencil, which he believed he still carried. But the result did show that there was a distinct advantage for the dazzle ships. One point must have struck all present that afternoon, namely, the very thorough manner in which Lieut.-Commander Wilkinson had gone into the whole subject. One only had to visit his school at the Royal Academy to see how carefully every type of ship was considered, the many experiments which were made in different lights, and so forth. He was perfectly sure that everything which could possibly be done had been done. Lieut.-Commander Wilkinson had alluded to the cost of the matter. This was really very small. In the aggregate, of course, it amounted to a considerable sum, but the cost of a little paint would very soon be wiped off by the saving even of one ship. It was really a great economy, even if only quite a few ships could be saved. And probably in the end it was a much greater economy than was generally conceived. The difficulty, of course, was to know how many ships were saved. The country owed a deep debt of gratitude to Lieut.-Commander Wilkinson for the work which he had so ably summarised in his interesting paper.

COMMANDER E. S. LAND, C.C. (United States Navy), said that he was a little prejudiced with regard to camouflage on his first introduction to the subject, now quite a number of years ago. It fell to his lot in the Navy Department to be what was

known as the "fool killer," that is to say, to size up inventions, applications for patents, and things of that sort, and to rule out those which were obviously impracticable or absurd. One of the first that he had to do with was a process for making a ship invisible. The idea caught the ear of someone in authority, and a ship was allotted to this inventor, who thereupon went to the Navy Yard and requested the captain to remove himself and his entire crew for forty-eight hours. This gave rise to some consternation, and in the end the whole thing was cancelled. As a result of that early experience he was afraid he had had a prejudice against such devices. He thought, however, that not only the Society, but the Allied nations of the world owed a debt of gratitude to Lieut.-Commander Wilkinson for the excellent work he had done. He and Lieut.-Commander Wilkinson had worked together in this matter, and although he (the speaker) had not always been able to agree with him, he was quite sure that a tremendous amount of good had been accomplished. The greatest trouble they had in America was that there were too many schools, and each artist or inventor swore that his was the one and only school. They were consequently camouflaged themselves in trying to determine what process to follow, and he thought that Lieut.-Commander Wilkinson did more than any other man to separate the sheep from the goats and get them into an agreed line. A good deal of time and money was spent on trying to secure invisibility, which was ultimately discarded in favour of the dazzle painting. He could go a long way with Lieut.-Commander Wilkinson on some of these points, but he was never able to follow him right through to the same conclusions. It seemed to him that one of the serious drawbacks was that while the process confused the eye, it did not confuse the azimuth circle; one might not be able to see the course of the ship, but by taking two lines of bearing in the ordinary way it could be arrived at. As to the German side of the subject, two contradictory views on the effect of dazzle painting appeared to have been current in Germany, one that dazzle painting did not bother the submarines at all, and the other that it did—especially at night! He rather questioned the seriousness of the confusion in the case of a single ship; in the case of a convoy the matter was different. At the same time they would all admit that when the instruments were put to work, such as the azimuth circle, or instruments of greater refinement, the value of the camouflage was materially reduced. The German submarines which surrendered at Harwich showed some of the enemy schools of thought with regard to this defence. But the majority of them had adopted the ordinary war grey with some slight modification here and there. There were, however, a few which followed the Chinese junk system, and had everything, from an evil eye on the bow to ordinary camouflage. As he had not had the advantage of reading the paper before the meeting, he was afraid he could not add more to the discussion, but he would like to repeat that the Allied countries, particularly Great Britain, France, and America, owed Lieut.-Commander Wilkinson a debt of gratitude.

MR. FRANK HOULDER said that he would like to tell the Society one thing which occurred to him. In September 1918 one of his firm's new ships on the Clyde was camouflaged. He went out to her on a tug, and presently he said, "Where's the ship?" They told him, "Why, there she is!" And when he looked the only thing he could be sure of was that it was not a ship!

MR. W. G. RAFFÉ said that he wished the author would apply his talents to the de-camouflaging of London. Various committees working on the housing question might do worse than invite Lieut.-Commander Wilkinson to restrict (or help, if they preferred) the activities of the bill-posters which disfigured the streets. He did not need to remind them that the streets in German cities were much more tidy than in ours, largely because bill-posting was restricted. Someone had said that the best place for posters was on the Underground; and there he would have 10 per cent. of the posters displayed on the platforms and the remainder posted about halfway between the stations! Seriously, some considerable help might be afforded if they reflected that camouflage was the exact antithesis of publicity. The same principles which had served for camouflage would, applied reversely, hold good for publicity. A scientific restriction of bill-posting—the same for all—would benefit both advertisers and the public. The Chairman had expressed some difficulty over the word "camouflage." The word arose out of Parisian theatrical slang, and the general meaning was "disguise," so that it had preserved its meaning in the new setting. Parisian actors talked about "putting on the camouflage."

THE CHAIRMAN proposed a vote of thanks to Lieut.-Commander Wilkinson, which was passed unanimously.

LIEUT.-COLONEL ALLAN J. C. CUNNINGHAM writes:—Referring to questions raised as to origin and meaning of the word "camouflage," after the paper of February 11th, I think the following is worth publishing:—

Re Camouflage.—The "Dictionnaire International Français-Anglais," by MM. H. Hamilton and E. Legros, Paris, 1880, gives—

"CAMOUFLET (Lat. *Calamo flatus*). 1. Smoke puffed in the air in the face of a person asleep. 2. Fig. (mystification), affront. 3. (mil. eng.) Camouflet, stifler."

PRODUCTION OF FIGS IN SPAIN.

Among the various fruit crops of Spain a prominent place must be assigned to the fig, because of its widespread cultivation throughout the

peninsula, and its general use as a food product. In a number of the provinces the fig leads all other fruits in importance. The dried fruit serves as food for a large portion of the poorer classes, and in years of great abundance it is also used for fattening pigs for the local markets.

In the report of a national survey of fruit-bearing trees made by the Government agronomists a few years ago, of a total of twenty-one varieties of fruit trees considered, the fig was assigned the fifth place of importance with regard to the value of the crop, being surpassed only by the orange, the almond, the algarroba (carob) and the chestnut, in the order named. Of the forty-eight provinces of Spain the fig was assigned the first place of importance among fruit trees by two provinces, and the second place by seven.

The fig tree grows throughout Spain, but reaches its highest development in the extreme south of the peninsula, where the climate is mildest, and in the Balearic Islands. At the time of the survey referred to, the Province of Murcia, on the Mediterranean coast, possessed the largest number of trees, 1,636,800, and produced a crop valued at about £157,000. The Balearic Islands followed with a total of 778,640 trees, and an estimated crop valued at about £47,000, Malaga Province coming next with 699,400 trees, and a crop estimated to be worth £92,000.

Although the survey was made nearly ten years ago, writes the United States Consul at Barcelona, there has been no considerable increase in the number of fig trees since that time, so that the figures arrived at by the survey can be accepted as showing the approximate status of fig-growing in Spain at the present time. According to this survey there were in Spain in 1910, 5,105,500 fig trees, of which number 1,272,960 were in regularly planted and cultivated orchards. The total area of these orchards amounted to 20,718 hectares (approximately 51,200 acres). The total production of figs during that year was 1,494,789 metric quintals (of 220·4 lb. each) valued at 15,310,883 pesetas (about £612,000). Owing to its hardiness only about one-fourth of the total number of fig trees is found in regularly planted commercial orchards, and very rarely is the fig tree given a place in the valuable irrigated lands. In the few cases in which the fig tree is planted in orchards it is set out 8 or 10 metres apart, while the spaces between the trees are closely cropped to vegetables or small grain, which is given the usual intensive cultivation employed in Spain.

The scattered fig trees receive very little care, and seem to require little except hoeing around the base of the tree in the spring and the removal of the dead branches. The Spaniard has a saying that the fig tree begins to bear at three years of age and lives for ever.

A number of the varieties of the fig tree in Spain produce two separate and quite distinct crops. The first crop matures during the months of June and July, and consists of a fruit known as the "breva," which has little market value, for it is quite perishable and cannot be dried as the regular fig of the later crop. It is pink in colour and about the same size and shape as the regular commercial fig, but very inferior to it in quality.

The second and much more important crop ripens during the months of July, August and September, and it is from this crop that the ordinary dried fig of commerce is obtained. As the fruit is sun-dried it is necessary that the picking be done only on clear, sunny days. The fruit is taken from the trees, spread upon mats made of a species of cane, and left in the sun to dry from ten to twelve days. During this period the fruit requires little attention, except turning every two or three days for more uniform drying. When it is properly dried it is carried in baskets to specially prepared sheds, in the case of large orchards, or to the owner's house or such other suitable place as may be available, and there is carefully graded as to size, colour, etc. It is then flattened out by hand and placed in rows in boxes for shipping. Those intended for export are packed in boxes of 10 kilos (22 lb.) each, and fruit for the domestic market in boxes of 25 kilos, or in small locally woven containers holding about 1 kilo.

The exports of dried figs from Spain during the years 1916–18 were 22,072,358 lb., 44,244,800 lb., and 34,194,200 lb. respectively.

COHUNE-NUT INDUSTRY IN HONDURAS.

Practically nothing had been done towards developing the cohune-nut industry previous to the world war. With the demand for combating the use of poison gas in the war, it was found that the shell of the cohune nut, when carbonised, acted as a preventive against the injurious effects of the gas. It therefore became the principal element used in the manufacture of the gas mask. There was, of course, need for millions of these, and the United States Government organised and set in motion the machinery for handling the industry on a large scale; but with the termination of the war the demand ceased. The utilisation of the cohune nut for war purposes, however, writes the United States Consul at Ceiba, served to encourage an industry which may be permanent, viz. the extraction of oil from the kernel of the nut.

The cohune (or corozo) nut is a product of the manaca palm, is indigenous to tropical countries, and is found mostly on low, damp lands, along creeks and rivers. It thrives best in the deep forest, and the greatest supply is found in virgin forest lands, of which there are extensive areas in Honduras.

The nuts grow in large oblong clusters, weighing probably 75 lb. each. A single tree will have from one to four clusters on it at a time, and with an average production of four clusters (300 lb.) a year to the tree. The nut varies in size from 1½ to 3 inches in length, and from 1 to 2 inches in diameter. The shell is hard and dense, with an

average thickness of ¼ to ½ inch. For cracking the nuts preparatory to extracting the oil, two varieties of machines are used. One is designated a "knuckle" machine, in which the nuts drop from a hopper between heavy knuckles, thus cracking the shell. The other is called an "impact" machine. It operates by a centrifugal motion, which propels the nut against the side of a large metal bowl with sufficient force to break the shell. The oil can then be extracted from this copra or crushed product.

The oil is high grade, said to be superior to coconut oil, and finds a ready sale for cooking purposes, the preparation of foods, or any use to which a good cooking oil may be put.

Honduras is said to be at present the most important source of cohune nuts in Central America. The greatest supply is found on the lowlands toward the eastern portion of the north coast. The Aguan River valley contains a single field of these nut-bearing trees extending sixty to seventy miles up the river from its mouth and with an average width of ten to twelve miles. Persons familiar with the industry who have been over this field estimate that an equipped force of 500 men could get 10,000 tons of nuts a month from this field alone. There are good prospects, adds the United States Consul, of this valley being reached by railway in the near future, thus furnishing transportation facilities for the development of the industry.

LACE INDUSTRY OF THE CHEFOO DISTRICT.

The art of lace-making was first taught to the Chinese of the Chefoo district by foreign missionaries twenty-five years ago. They believed that by teaching lace-making the women and girls would find profitable employment within their own homes, and the subsequent spread of the industry has fully justified their efforts. Although first taught in Chefoo, Chi Hsia Hsien was the first district in which lace was extensively made. The city of Chi Hsia, the centre of the district, is about thirty-five miles south-west of Chefoo. There torchon laces were first made of silk thread and found a limited retail market in the city of Chefoo.

In 1895 a British missionary established an institution called the Chefoo Industrial Mission and commercialised the lace industry. With a small beginning in local retail sales, retail exporting followed and gradually developed into wholesale transactions. About fifteen years ago, writes the United States Consul at Chefoo, the making of thread laces was introduced, and with the use of Belgian and French patterns Chefoo first entered into competition with European laces.

The original laces being made of silk, the industry was self-centred as Chinese-made silk-thread was used. After the introduction of thread laces both linen and cotton thread were imported exclusively from England. Owing to the war's interruptions supplies were irregular and at times ceased, and Japanese cotton thread entered the market.

Chi Hsia supplies fully 50 per cent. of the laces of the Chefoo district. The finest laces come from Ching Chou, which is thirty miles west of Weihsien. This city markets its lace largely through Chefoo. The Ching Chou laces are the closest patterns made in Shantung Province, some requiring more than 300 bobbins in their manufacture.

The principal kinds of lace manufactured in the district are Torchon and Cluny, the former being marketed mainly in Australia, and the latter in America. In addition a small quantity of filet lace, a new kind for the Chefoo district, is made, and imitation Maltese lace is also turned out to a limited extent.

Torchon and Cluny laces were originally made in this district according to the general method of making bobbin lace by hand; that is, fastening the design on a specially constructed cushion, inserting pins at the points of intersection, and passing the bobbins back and forth in front of the pins according to the design and the kind of lace being made. An improvement was later made by using a cylinder approximately three inches in diameter which revolves above a flat board on which the bobbins rest, in place of the cushion. The pattern is attached to the cylinder so that when it is revolved the design is continuous. In this way the pins are removed and advanced as required, and the finished lace passes over the back of the cylinder. Under the former system, the design being of limited length, it was necessary to remove all the pins and shift the unfinished end of the lace to the top of the design in order to continue the work. In the Ching Chou district lace is still made in the old way on cushions.

Filet lace is made by using a knitted mesh which is stretched over a frame, the pattern being embroidered with a needle.

The number of bobbins used in making lace varies from 8 to over 500, according to the kind and the design. The simplest patterns of Cluny laces of narrow width require the minimum, whereas wide torchons of intricate design require the maximum. As more than 300 different designs and widths of torchons and Cluny laces are made in the Chefoo district, it is difficult to use a standard by which comparisons may be made. Generally, a yard of torchon, 1 inch in width, requires from 28 to 40 bobbins of thread, the number being governed by the design, whereas from 36 to 44 bobbins are required to make a yard of Cluny lace 1 inch wide.

There are from 30 to 50 yards of thread on a bobbin, depending on the size of the bobbin, which, being crudely made by local carpenters, varies considerably, and the number of the thread used. Although the amount of thread used in making lace slightly varies the cost, the main difference is governed by the number of bobbins necessary to make a given pattern. The bobbins are wound by hand.

Until the European war upset trade conditions, English thread was used almost entirely in the

Chefoo lace-making industry. The war, however, as mentioned above, enabled threads of Japanese manufacture to enter into serious competition with those of English make in the local market. Lace made from Japanese thread, although its initial appearance is satisfactory, is, says the United States Consul, defective in wearing qualities, and after being washed the strands of the thread separate and the lace becomes uneven and loose.

Thread is distributed to the workers by native brokers who pay for the labour and collect and sell the finished lace to the exporters. The work is done in the homes of the lace makers and payment is made by the yard according to the number of bobbins used, the kind of lace, and the pattern. A skilful worker, devoting an entire spring day, can complete 2 yards of torchon lace 1 inch in width for which she will receive 500 cash (about one shilling) for her labour.

Laces are graded into three classes. Those falling below the third quality are rejected by responsible exporters and disposed of as job lots. Qnality is governed, in addition to the different kinds of thread, by workmanship, cleanliness, firmness, and evenness of pattern. Cleanliness is most important as the lace cannot be washed before it is sold. Considerable skill is required to grade laces, as only an expert can judge what the appearance will be after wear and washing.

CORRESPONDENCE.

CONFERENCE ON HOUSE FURNISHINGS.

May I correct an error in your report of my remarks in the discussion at the "Conference on House Furnishings"?

I am reported as saying that "there was not a single cottage in the Exhibition suited to the taste or purse of a cottager." What I really said was "there was not one cottage *furnished* for the needs of a cottager." I should also like to add that if furniture designers and makers would only realise the truth that good proportions, good lines, and pleasant colour, cost less than bad ones and unpleasant colour; and if the public would look for essentials in furniture rather than showy, useless features, we should have the cheaper types of furniture brought out of the "nasty period," so aptly described by Mr. Bianco in his remarks on the more costly productions.

PERCY A. WELLS.

GENERAL NOTES.

INDIA'S FOREST RESOURCES.—On April 19th, 1917, a paper by Mr. R. S. Pearson, F.L.S., on "The Recent Industrial and Economic Development of Indian Forest Products" was read before the Indian Section of the Society. Sir Robert W. Carlyle, late Revenue and Agricultural Member of the Government of India, who presided on the occasion, referred to the possibility of very great developments, with a sufficiently adequate staff, more roads, and the best mechanical means of extracting the timber. In view of these problems the Government of India has recently decided to create a Forest Engineering Service, paid on the same scale as the Imperial Forest Service. It is proposed that the recruits to the new service should be trained in Canada and the United States, where, it is pointed out, the subject of timber extraction and utilisation has long been studied, and improved methods have been introduced under conditions approximating to those encountered in many parts of India and Burma.

SYNTHETIC DYES.—An article in the *Board of Trade Journal*, February 5th, points out that while there are many gaps in the range of dyes now being produced by British makers, the position is distinctly hopeful, and that there is every ground for the belief that the main difficulties inherent in the creation of so complicated an industry as the coal-tar chemical industry have been successfully surmounted. It took the Germans forty years to reach their present position, and it cannot be expected that we can attain the same position, even with the valuable stimulus of a five-year war period, in much less than ten to fifteen years. Hence the proposal for the temporary protection of the industry for a limited period. The present output of dyes in this country is not less than 25,000 tons per annum.

HOME-GROWN TIMBER.—It appears from an answer given to a question in Parliament that the sales of the Home-grown Timber Department last year approximated in value to £3,700,000. The Department, it was mentioned, is being wound up as rapidly as possible. There are still about 6,500 workpeople—sawyers, fellers, etc.—on its pay roll.

SOLID LUBRICANTS.—The Advisory Council of the Committee of the Privy Council for Scientific and Industrial Research have published a Memorandum on Solid Lubricants which has been prepared by their Lubricants and Lubrication Committee. This Committee was appointed in July 1917 to survey the field for research on Lubricants and Lubrication, and in the course of their work dealt with the question of Solid Lubricants. The Memorandum embodies existing knowledge on the subject, but the Advisory Council desire that the Bulletin should be regarded rather as a summary of existing literature than as an authoritative statement based upon actual research work. The subject is dealt with under the following main headings: (1) Characteristics of Solid Lubricants. (2) Action of Solid Lubricants. (3) Analyses of Lubricating Graphites. (4) The Grading of Graphite. (5) Hot Bearings. (6) Methods of Applying Solid Lubricants. (7) Drawbacks to the use of Colloidal Solid

Lubricants. (8) Observations on Results obtained by the use of Solid Lubricants. The Bulletin is published by H.M. Stationery Office and may be purchased through any bookseller, or directly, price 6*d*. net, from H.M. Stationery Office.

USE OF RARE SUGARS.—The so-called rare sugars are used to a considerable extent by the Army Medical Corps and by the medical profession in general. One of the principal uses to which they are put is the differentiation of bacteria, for which purpose they are invaluable. For some time the United States Bureau of Standards has had presented to it for test a number of these rare sugars. Owing to the large demand for one of these sugars, known as d-Mannite, the Bureau undertook, at the request of the United States War Department, the production of a considerable quantity of this substance. The source of supply is a crude manna. The Bureau's investigations finally developed a method whereby pure white crystals of d-Mannite can be produced by two crystallisations from the crude manna. It has thus become possible to produce relatively large quantities of this valuable substance at a reasonable cost.

EMPIRE TIMBER EXHIBITION. — An "Empire Timber Exhibition" will be held at the Holland Park Skating Rink from July 5th to July 17th. It is being organised by the Department of Overseas Trade with the primary object of bringing prominently before architects, inspectors, and firms required to specify timbers in their contracts, as well as before users and consumers, the full range of Imperial grown timbers, and especially those kinds which up to the present are only slightly, if at all, known in this country. It is also desired at the same time to demonstrate the chief uses for which such timbers are suitable. Almost all the self-governing Dominions, Crown Colonies, and Protectorates have definitely decided to participate. A limited amount of space will be available for the use of traders in this country in which to display specimens of articles manufactured from timbers grown within the British Empire.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday afternoons, at 4.30 p.m.:—

MARCH 17. — WILLIAM WORBY BEAUMONT, M.Inst.C.E., "Street Passenger Transport of London." KENNEDY JONES, M.P., Chairman, Select Committee on Transport (Metropolitan Area), will preside.

MARCH 24.—L. GASTER, "Industrial Lighting in its relation to Efficiency." SIR HENRY TRUEMAN WOOD, Chairman of the Council, will preside.

APRIL 14.—JOSEPH THORP, "The Fundamental Basis of Good Printing."

APRIL 21.—AIR-COMMODORE EDWARD MAITLAND, C.M.G., D.S.O., A.F.C., "The Commercial Future of Airships."

APRIL 28.—CHARLES H. SHERRILL, "Stained Glass."

MAY 5.—DR. C. E. KENNETH MEES, "A Photographic Research Laboratory." SIR HENRY TRUEMAN WOOD, Chairman of the Council, will preside.

MAY 12.—

MAY 19. — JOHN SOMERVILLE HIGHFIELD, M.Inst.C.E., M.I.E.E., "Electrical Osmosis."

INDIAN SECTION.

Friday afternoon, at 4.30 p.m.:—

MARCH 19.—SIR WILLIAM S. MEYER, G.C.I.E., K.C.S.I., Financial Member of Council of the Governor-General of India, 1913-18, "The Indian Currency System and its Developments." THE RIGHT HON. LORD CHALMERS, G.C.B., LL.D., will preside.

Thursday afternoons, at 4.30 p.m.:—

APRIL 15.—BRIGADIER-GENERAL LORD MONTAGU OF BEAULIEU, C.S.I., "Roads and Transport in India."

MAY 20.—SIR GEORGE CUNNINGHAM BUCHANAN, K.C.I.E., M.Inst.C.E., "The Ports of India: their Administration and Development."

Monday afternoon, at 4.30 p.m.:—

MAY 31. — ALBERT HOWARD, C.I.E., M.A., A.R.C.S., F.L.S., Imperial Economic Botanist to the Government of India, "The Improvement of Crop Production in India." SIR ROBERT W. CARLYLE, K.C.S.I., C.I.E., will preside.

Date to be hereafter announced:—

SIR VALENTINE CHIROL, "The Enduring Power of Hinduism." (Sir George Birdwood Memorial Lecture.)

COLONIAL SECTION.

Tuesday afternoon, at 4.30 p.m.:—

MAY 4.—PROFESSOR WILLIAM A. BONE, D.Sc., Ph.D., F.R.S., "Lignite."

INDIAN AND COLONIAL SECTIONS.
(Joint Meeting.)

Friday afternoon, at 4.30 p.m.:—

JUNE 4. — PROFESSOR SIR JOHN CADMAN, K.C.M.G., D.Sc., F.G.S., M.Inst.C.E., "The Oil Resources of the British Empire."

Dates to be hereafter announced:—

GRAILY HEWITT, "Rolls of Honour."

CHARLES CROWTHER, "The Arts and Crafts

of Japan" (with examples from the author's private collection).

WILLIAM CRAMP, D.Sc., M.I.E.E., "Pneumatic Conveying Plants, with special reference to the Transport of Grain."

CANTOR LECTURES.

Monday evenings, at 8 p.m.:—

WALTER ROSENHAIN, B.A., D.Sc., F.R.S., Superintendent, Department of Metallurgy and Metallurgical Chemistry, National Physical Laboratory, "Aluminium and its Alloys." Three Lectures.

April 12, 19, 26.

ARTHUR THOMAS BOLTON, F.R.I.B.A., F.S.A., Curator, Soane Museum, "The Decoration and Architecture of Robert Adam and Sir John Soane, 1758–1837." Three Lectures.

May 3, 10, 17.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MARCH 15...Chadwick Public Lecture, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5.15 p.m. General Sir John Goodwin, "Military Hygiene in Peace and War." (Lecture II.)

Victoria Institute, Central Hall, Westminster, S.W., 4.30 p.m. Mr. E. W. G. Masterman, "The Walls of Jerusalem at Various Periods."

Surveyors' Institution, 12, Great George-street, S.W., 8 p.m. Mr. T. H. Bailey, "The Third Report of the Acquisition and Valuation of Land Committee on the Acquisition for Public Purposes of Rights and Powers in Connection with Mines and Minerals."

Geographical Society, 135, New Bond-street, W., 8.30 p.m. Professor J. L. Myres, "The Dodekanese."

East India Association, 3, Victoria-street, Westminster, S.W., 3.45 p.m. Mr. N. N. S. Gupta, "The Agricultural Development of India."

British Architects, Royal Institute of, 9, Conduit-street, W., 8 p.m. Mr. H. A. Hall, "The Planning of American Departmental Stores."

TUESDAY, MARCH 16...Petroleum Technologists, Institution of, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5.30 p.m. Messrs. M. A. Ockenden and A. Carter, "Plant used in the Rotary System of Drilling Oil Wells."

Royal Institution, Albemarle-street, W., 3 p.m. Professor A. Keith, "British Ethnology: the Invaders of England." (Lecture III.)

Civil Engineers, Institution of, Great George-street, S.W., 5.30 p.m. Sir Alexander Kennedy, "Exhibition of Lantern Views taken throughout the War Areas in France and Flanders."

Anthropological Institute, 50, Great Russell-street, W.C., 8.15 p.m. 1. Surgeon-General R. Buddle, "Exhibition of Flint Implements from Russia." 2. Mr. N. W. Thomas, "The Ovia Secret Society."

Zoological Society, Regent's-park, N.W., 5.30 p.m. 1. Mr. R. I. Pocock, "On the External Characters of South American Monkeys." 2. Dr. C. F. Sonntag, "The Comparative Anatomy of the Tongues of the Mammalia. I.—General Description of the Tongue."

WEDNESDAY, MARCH 17...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Mr. W. W. Beaumont, "Street Passenger Transport of London."

Aeronautical Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Major C. F. Abell, "Airship Machinery: Past Experience and Future Requirements."

Meteorological Society, at the Royal Astronomical Society, Burlington House, W., 5 p.m. Captain C. K. M. Douglas, "Clouds as seen from an Aeroplane."

United Service Institution, Whitehall, S.W., 3 p.m. Major H. F. S. Huntington, "The Physical and Ethical Value of Boxing."

Electrical Engineers, Institution of (Wireless Section), at the Institution of Civil Engineers, Great George-street, S.W., 6 p.m. Captain P. P. Eckersley, "Duplex Wireless Telephony: Some Experiments on its Application to Aircraft." (South Midland Section.) The University, Birmingham, 7 p.m. Major K. Edgcumbe, "The Protection of Alternating Current Distribution Systems without the Use of Special Conductors."

Industrial League and Council, Central Hall, Westminster, S.W., 7.30 p.m. Discussion on "Our League: how can we improve it."

THURSDAY, MARCH 18...Cold Storage and Ice Association, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5 p.m.

Royal Society, Burlington House, W., 4.30 p.m.

Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Linnean Society, Burlington House, W., 5 p.m. Dr. J. Small, "The Chemical Reversal of Geotropic Response in Roots and Stems."

Chemical Society, Burlington House, W., 8 p.m. 1. Messrs. I. Masson and R. McCall, "The Viscosity of Nitrocellulose in Mixtures of Acetone and Water." 2. Messrs. H. Stephen, W. F. Short, and G. Gladding, "The Introduction of the Chloromethyl Group into the Aromatic Nucleus." 3. Mr. H. E. Cox, "The Influence of the Solvent on the Velocity of Reaction between certain Alkyl Iodides and Sodium β-naphthoxide." 4. Messrs. H. Crompton and P. L. Vanderstichele, "The Use of 1:2 Dichlorvinylethyl Ether for the Production of Chloracetates and Acid Chlorides."

Royal Institution, Albemarle-street, W., 3 p.m. Mr. S. Graham, "The Spirit of America after the War." (Lecture I.)

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Mr. C. Crowther, "Things Japanese."

Electrical Engineers, Institution of, at the Institution of Civil Engineers, Great George-street, S.W., 6 p.m. Discussion on papers:—1. Mr. W. H. Patchell, "Notes on Operating a By-product Producer Gas Plant for Power and Heating." 2. Mr. S. H. Fowles, "Production of Power from Blast Furnace Gas."

Numismatic Society, 22, Russell-square, W.C., 6 p.m.

Mining and Metallurgy, Institution of, at the Geological Society, Burlington House, W., 5.30 p.m. Mr. W. R. Jones, "Tin and Tungsten Deposits: The Economic Significance of their Relative Temperatures of Formation."

FRIDAY, MARCH 19...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Indian Section.) Sir William S. Meyer, "The Indian Currency System and its Developments."

Royal Institution, Albemarle-street, W., 9 p.m. Mr. E. McCurdy, "Leonardo da Vinci."

Concrete Institute, 296, Vauxhall-bridge-road, S.W., 6 p.m. Dr. O. Faber, "Notes on the Practical Applications of Reinforced Concrete."

SATURDAY, MARCH 20...Royal Institution, Albemarle-street, W., 3 p.m. Professor Sir J. J. Thomson, "Positive Rays." (Lecture V.)

Journal of the Royal Society of Arts.

No. 3,513. VOL. LXVIII.

FRIDAY, MARCH 19, 1920.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

Wednesday, March 24th, at 4.30 p.m. (Ordinary Meeting.) L. Gaster, "Industrial Lighting in its Relation to Efficiency." Sir Henry Trueman Wood, Chairman of the Council, will preside.

FOURTEENTH ORDINARY MEETING.

Wednesday, March 17th; Mr. William Kennedy Jones, M.P., Chairman of the Advisory Committee on London Traffic, in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Barker, Frederick Walter, London.
Barnsley, Frank Herbert, Dudley.
Burlin, Adolph L., Ph.D., Manchester.
Butterworth, Charles Frederick, Poynton, near Stockport.
Corker, James S., Manchester.
Farrar, George Edward, Richmond, Surrey.
Hoffman, Frederick L., LL.D., Newark, New Jersey, U.S.A.
Lomas, Leslie H., B.Sc., Prestbury, Cheshire.
Oxley, Ernest C. F., Sioux Lookout, Ontario, Canada.

The following candidates were balloted for and duly elected Fellows of the Society:—

Crook, Charles W., B.A., B.Sc., London.
Ford-Moore, Lieut.-Colonel A. P., London.
Frazer, E. D., London.
Hough, Lynn Harold, Evanston, Illinois, U.S.A.

A paper on "Street Passenger Transport of London" was read by Mr. William Worby Beaumont, M.Inst.C.E.

The paper and discussion will be published in a subsequent number of the *Journal*.

PROCEEDINGS OF THE SOCIETY.

TENTH ORDINARY MEETING.

Wednesday, February 18th; Mr. Neville Chamberlain, M.P., in the chair.

The paper read was—

ENGLISH CANALS AND INLAND WATERWAYS.

By Sidney Preston, C.I.E.

The question of transport has been much to the fore during the past year, and the canals of the country are of some considerable importance in this consideration. This probably accounts for my having been asked to read a paper before this Society on them. You will notice that I have called the paper "English Canals and Inland Waterways." I have done this on purpose, as I have had nothing to do with those in Scotland, and have seen nothing of those in Ireland.

The canals in England divide themselves into two main groups, namely, those that are owned or controlled by railway companies and those that are owned and controlled by independent companies or bodies. Early in the war the independent canals began to be seriously depleted of their staff and the boatmen trading on them, so that there was serious risk of many of them having to be closed down for want of men. Moreover, the great increase in wages, prices of material, etc., had so increased the maintenance and working expenses that it was proving impossible for the companies to carry on at their statutory rates and tolls in competition with the railway freight rates, which at that time had not been increased.

It was therefore decided by Government to take over the control of the main arterial lines, and this was done from March 1st, 1917. Subsequently, some carrier companies also came under control.

It is not necessary to say much about the Canal Control Committee, as it was a war measure, but it is mentioned as for the moment it introduces a new category into the canal system, which may be now classified as follows:—

1. Railway owned or controlled.
2. Controlled by Government.
3. Independent.

The Control Committee assisted the canals in the following ways :—

1. Issued cards protecting men over twenty-five years of age from military service.

2. Agreed to pay a war bonus to the establishment employed.

3. Supplemented the depleted staffs by men from Transport Workers' Battalions.

4. Assisted the companies to obtain necessary material or priority orders for work.

5. Negotiated for the return of men who had been in their employ.

6. Controlled the sale and transfer of canal boats.

7. And most important—it guaranteed to the companies the net revenue they earned in a standard year, which in most cases was 1913.

The amounts of compensation paid on the English canals alone has been :—

In 1917	£410,300
,, 1918	748,038
,, 1919 (approximate) . .	994,494
	£2,152,832

Besides this, the following compensation was also paid to the carrying companies who came under control :—

In 1917	£9,678
,, 1918	36,549
,, 1919 (approximate) . . .	53,284
	£99,511

making a total of £2,253,343.

It is extremely difficult to find anything to say about canals which has not been said time after time. Generally it is correct to say that they are in exactly the same condition as they were when originally constructed towards the end of the eighteenth century, and the early part of the nineteenth century. Then came the beginning of the railway era, and canals passed into the background and to a large extent came under the control or ownership of railway companies.

It seems to me that, instead of detailing the numerous disabilities from which the English canal system suffers, it may serve a useful purpose to refer to the numerous endeavours which have made been in the last forty years to get some improvement made in it. For this purpose I will start with the Select Committee which was appointed on February 22nd, 1883, "to inquire into the conditions and the position of the canals and internal navigations of the country, to report thereon, and to make such recommendations as may appear necessary."

The original Committee consisted of fifteen members, one of whom was discharged on April 26th, 1883, while two more had been added on April 18th. Thus the Committee really consisted of sixteen members.

On May 21st, 1883, the Canal Boats Act (1887) Amendment Bill was read a second time and committed to the Committee.

This Committee held eleven sittings and examined the following witnesses :—

1. Mr. H. G. Calcroft, Assistant Secretary, Railway Department, Board of Trade.
2. Mr. E. J. Lloyd, Engineer and Manager, "Warwick" Canals.
3. Mr. W. H. Bartholomew, Engineer, Aire and Calder Canal.
4. Mr. James Abernethy, President, Institute of Civil Engineers.
5. Mr. W. Evans, solicitor to Birmingham Canal Navigation.
6. Mr. J. Allport, Manager, Midland Railway.
7. Mr. J. S. Watson, iron steam-barge builder, Blackwall.
8. Mr. W. B. Clagram, Engineer and Superintendent, Sharpness New Docks and Gloucester and Berkeley Canal.
9. Mr. Thorpe, partner in Barkworth & Spalding, of Hull and Gloucester, timber and slate merchants.
10. Mr. J. H. Taunton, engineer and manager, Thames and Severn Canal.
11. Mr. F. R. Conder, M.Inst.C.E.
12. Mr. S. F. Vernon Harcourt, C.E.
13. Mr. F. Morton, of Fellows Morton & Clayton, canal carriers.
14. Mr. J. Hunt, canal carrier, of Leeds.
15. Right Hon. Sir H. Bartle Frere.
16. General F. Rundall, R.E.
17. Mr. G. Smith, of Coalville.
18. Right Hon. Sir F. Peel, Chairman, Railway Commissioners.
19. Mr. C. F. Clark, ironfounder, Wolverhampton.
20. Mr. F. S. Powell, Chairman, Canal Association.

In addition to the verbal evidence given by these witnesses many notes and statistical tables were put in, all of which are published with the report of the Committee.

Thus much useful information was collected, but the Committee came to no conclusion, nor did it make any recommendations, its report, which was dated July 12th, 1883, being in the following terms: "Your Committee have examined several witnesses upon the subject and upon the Bill referred to them, but as it will not be in their power to conclude the investigation in the present session, they have agreed to report the evidence already taken before them and to recommend that the Committee should be reappointed in the next session of Parliament." The Committee also agreed to report the Canal

Boats Act (1877) Amendment Bill without amendment.

The Committee was not reappointed. It will be seen that the list of witnesses includes canal and railway engineers, and managers, boat builders, traders, canal carriers and independent men, and it is much to be regretted that the time spent and information obtained led to no practical result.

In 1884 General Rundall, R.E., read a paper before this Society, in which he enumerated the advantages and defects of canal carriage as follows:—

Advantages:

1. Goods can be carried in the most economical manner suited to them, without interference with any other class.

2. Boats can load and unload at any point, and can receive or discharge cargoes from or to ships direct.

3. Dead weight to be moved, in proportion to the load, is a minimum.

4. Capacity of canal for traffic is practically unlimited, if locks properly designed.

5. No obligation on canal company to provide expensive plant, as boats will be provided by traders.

6. Almost total absence of risk to cargoes, therefore insurance is a minimum.

The defects are:

1. Absence of unity of management.

2. Want of uniformity in gauge of the canals and locks.

3. With few exceptions, not capable of being worked by steam.

4. Unequal system of tolls.

5. So many links in the communications being in the hand of railways.

On May 10th and 11th, 1888, this Society held a conference on the Canals and Inland Waterways, when the following papers were read and discussed:—

1. Canal Engineering, its Past, its Present Aims, and its Prospects in the Future, by S. F. Vernon-Harcourt, M.A.

2. History, Rise and Progress of Canal and River Navigation in Great Britain and Ireland, by M. B. Cotsworth.

3. History of the Rise and Progress of Waterways and Railways in England and Wales, and their Mutual Influence on each other, by W. A. Forbes.

4. Inland Navigation in Great Britain, by E. J. Lloyd.

5. Present Condition of Inland Navigation in the United Kingdom, with Suggestions for its Improvement, by M. B. Cotsworth.

6. Inland Transport in the Nineteenth Century by Land and Water, by F. R. Conder.

7. Transport by Canals and Railways, by G. Lester.

8. Canals and Inland Navigations properly National Works, by General Rundall, R.E.

9. Some Remarks on the Canals and Inland Navigations of France, Belgium and Holland, by W. J. C. Moens.

10. Improvements in Canal Communication, by Samuel Lloyd.

11. Inland Transport a New Departure, by S. Lloyd.

12. Relative Cost of Transport by Railway and Canal, by W. Shelford.

13. Water Transport, by Colonel W. M. T. Campbell.

Besides these there were special articles on:—

14. Canals and Shallow-draft Steam Navigation of Canal.

15. River Weaver Navigation.

16. Kennet and Avon Canal.

17. Improvement of the Water Communications between London and Birmingham.

18. Maintenance of Canals in Mining Districts.

19. Capabilities of the River Severn as an Inland Navigation.

20. The Laws of Canals.

It will be noticed that many of the papers were contributed by men who had given evidence before the Select Committee in 1883.

The first thirteen papers contain a complete history of the growth of the canal system, set out their many defects, indicate in what way they might be improved to become of greater national importance and usefulness, discuss the much vexed question of the effect on water communication of the ownership or control of canals by railway companies, point out the urgent necessity for the unification of the standard dimensions of canals, the necessity for the elimination of the numerous small companies, and discuss the advantages of State ownership.

The last seven papers deal with individual waterways, and are not so interesting for my purpose, except perhaps the one about the improvement of water communication between London and Birmingham. It would be impossible, in the time at my disposal, adequately to summarise all the papers; but I venture to think that at this time, when the fate of the canals of the country will shortly be under the consideration of the Ministry of Transport, it may be of value to bring these papers prominently to light. They are all written by men keenly interested in water transport, and I

would suggest that if the Society has still a few copies left of the pamphlet it published as a result of the conference, they could not be put to better use than to be transferred to the new Ministry for the perusal of those who will have the deciding of the general question regarding the future of inland navigation. As far as I can judge, the case for water communication is put as strongly as possible, and it will be for the Ministry to decide whether the arguments are sound or not.

You may wonder what results were obtained from this conference? As far as I am aware none whatever.

The next move was the appointment of the Royal Commission on Canals and Inland Navigations of the United Kingdom. This Commission was apppointed on March 5th, 1906.

The terms of reference were as follows:—

To Inquire into the Canals and Inland Navigations of the United Kingdom, and to report on:—

1. Their present condition and financial position.

2. The causes which have operated to prevent the carrying out of improvements by private enterprise, and whether such causes are removable by legislation.

3. Facilities, improvements and extension desirable, in order to complete a system of through communication by water between centres of commercial, industrial, or agricultural importance, and between such centres and the sea.

4. The prospects of benefit to the trade of the country, compatible with a reasonable return on the probable cost.

5. The expediency of canals being made or acquired by public bodies or trusts, and the methods by which funds for the purpose could be obtained and secured, and what should be the system of control and management of such bodies or trusts.

The report of this Commission may, indeed, be said to be a monumental work in eleven volumes. These contain three interim reports, issued on November 26th, 1906, October 30th, 1907, third Report October 12th, 1909, and a fourth and final report of the same date.

It will be interesting to see briefly what the recommendations in the main report were, and what were the reservations or qualifications in the subsidiary memoranda. Its recommendations were:—

1. The appointment of a Central Waterways Board for Great Britain.

2. The four main routes generally spoken of as "the Cross" to be vested in the Board, to whom the administration of all waterways vested in them should be entrusted.

3. That if for financial, or other reasons, the larger works of improvement recommended have to suffer some postponement, the unification of these waterways and the transfer of their administration to the Waterways Board should be effected without delay. This was considered most important, especially if accompanied by minor improvements and some reduction of tolls on unification.

4. The Waterways Board to review the whole situation on the lines of practical business with special regard to finance and benefit to trade and public interest, to the extent of local assistance, prospect of traffic and to competition of railways. It should prepare schemes for submission to Parliament.

5. It should propose further schemes from time to time when satisfied of the expediency of acquiring and unifying any further waterways, either as branches or feeders.

6. The acquisition of waterways now in the hands of railway companies should be included in the earlier schemes.

7. It is worthy of consideration whether the collection of information as to the flow of rivers and streams and as to water supplies in Great Britain, where there are navigable waterways, should not also be entrusted to the Waterways Board.

8. The Commission indicated the financial assistance the State should give for the acquisition and improvement of the waterways forming "the Cross."

There were many other recommendations, but it is impossible to mention them all in this paper.

The Commission consisted of nineteen members, all of whom signed the report except Messrs. J. F. Remnant, R. C. H. Davison and J. C. Inglis, who put in reports of their own; while Lord Farrer, Sir John Wilson, Mr. Waldron and Mr. Killick put in a memorandum and reservations on the report; Lord Farrer attached an additional note, and Mr. Russell Rea put in a memorandum of reservation.

It would be well to state briefly what were the reasons for the dissent of three members of the Commission and the additional notes and reservations of others. Mr. Remnant considered the report inconclusive, thought the inquiry they had made was sufficient to enable a final decision to be formed on the questions raised by the terms of reference, and was of opinion the evidence did not warrant any steps

being taken in the direction indicated by the report so long as the main factors then governing the transport of goods in this country continued to operate. On the main heads of the inquiry his opinion was :—

1. That the canals are a declining industry, being replaced by the cheaper and more expeditious railways. That the tendency of traders is to hold small stocks, relying on quick replenishments, and this would militate against the larger 100-ton barges advocated.

2. That the State would not be justified in finding capital to bolster up an obsolete system.

3. The cost of the scheme advocated would be enormous, and there was no evidence to show that trade would use it. It seemed likely the probable cost has been underestimated.

4. It was inadvisable that a board should be formed to acquire, administer or deal with the waterways.

Mr. Davison agreed with the report that any controlling authority should not become carriers, as the State should not compete with the privately-owned railways. He did not think the circumstances of the English canals were similar to those on the Continent. He questioned whether the 100-ton consignments will suit the present system of trade, and considered further information was necessary on financial points, while he questioned the accuracy of the traffic estimate. Generally, he considered railways more efficient, and that the State should not subsidise a decaying industry. Mr. Inglis, who was Chief Engineer of the Great Western Railway, considered this country really unsuitable for canals, owing to its configuration, and that the system is obsolete; that the State should not subsidise a decaying industry against railways, the capital for which was raised privately. The scheme proposed would favour works situated on the canals at the expense of those not so situated. He contended that no analogy could be drawn from the success of the Continental canals, and that we should not attempt to copy them. He considered the estimates of cost and traffic unreliable and incomplete in many items that he specified. He thought the setting up of a system of State-aided canals would arrest railway development, and that any State aid must be given to all forms of transport alike.

Lord Farrer took exception to the proposition that it is the business of the State to provide the best and most economical mode of transport if private enterprise failed to do it, as he held that this was favouring certain traders at the expense of others.

Mr. Russel Rea, though signing the report, objected to the recommendations that the Rivers Trent and Severn should be improved so as to pass boats of 750 tons to Nottingham and Worcester, and of 600 tons to Stourport. He objected on two grounds :—

1. Because he thought the 100-ton gross scheme a sufficient programme to engage the attention of a Waterways Board.

2. He had no confidence in the utility or prospects of any return from them.

The memorandum by Lord Farrer, Messrs. Wilson, Waldron and Killick, took exception to the proposition in the report that it is the duty of the State to provide cheap transport to inland districts. It stated that the report was based on the underlying assumption that improved waterways would supply cheap transit as compared with railways. In regard to this, they thought there were some general considerations which should be stated. Thus, water carriage by sea is undoubtedly cheaper than any other method of transport, the reasons being :—

(*a*) The existence of an ample waterway open to all carriers free of charge.

(*b*) The enormous reduction of the effort of traction necessary to remove a given weight as compared with other methods.

They held that the benefit this affords can only be obtained so far as, and in proportion to, the extent to which similar conditions can be created. They admitted that to a certain extent these advantages are obtainable on Continental waterways, but maintained that the economic conditions of France, Belgium and Germany cannot be reproduced in England. They could not agree that because it is not proposed that the State should become carriers the objection of State improvement of waterways is removed or diminished, and that therefore the question of the State improving inland navigation to compete with privately-owned railways requires further consideration. The evidence laid before the Commission had not satisfied them that there will be any reasonable return on the capital invested in acquisition and improvement of the waterways. They also thought that though the improved canals might tend to lower rates where they compete with railways, this fact would tend to prevent reductions elsewhere. Nor did they support the recommendation that further restrictions should be placed upon railway companies to protect State-owned waterways, or the suggestion that the cost of acquisition of waterways as distinct from their improvement should be borne by the State, either without any pecuniary

return or on other and less onerous terms than apply to outlay on improvements.

Ten years have passed since this valuable report was issued, but there has been no outcome from it. It is true that during five of these years we have been at war, but it must not be forgotten that five years elapsed between the conclusion of the inquiry and the outbreak of the war, during which time steps might have been taken to give effect to the recommendations, or some of them at least; but, as far as I am aware, nothing was done. To an ordinary person it does seem extraordinary that the three years' labour and expense of a strong Royal Commission should be thus thrown away.

I desire also to refer to the second report of the Select Committee on Transport published on November 14th, 1918. The reference to canals is very brief, and concludes as follows: "There can be no question that the arrangements which have been made for the working of the canals during the war have been of great public value and have relieved the railways of a considerable volume of heavy traffic with which they found it difficult to cope. Your Committee, in the absence of further evidence which it desired to take, has not been able to come to any conclusion in regard to the most advantageous organisation for dealing with the canals, except that further amalgamation would be advantageous."

Finally, I wish to refer to two lectures given by Mr. R. B. Dunwoody at the Institution of Civil Engineers on the 16th and 30th of last month. These were the Vernon Harcourt lectures, his subject being "The Economic Requirements for Inland Navigation Transport in the British Isles." Mr. Dunwoody was Secretary of the Royal Commission and of the Canal Control Committee, and has, therefore, an intimate knowledge of the canal systems of the country. His two lectures contain a most able *résumé* of the whole subject of inland navigation in this country.

What, then, is the position of the canals of England at the present day? I may safely say that, to all intents and purposes, they are in the same condition as they were when constructed in the eighteenth century. It is true that the Aire and Calder Canal did lengthen its locks so that they can now pass a train of twenty-five compartment boats. They have also improved and developed the Port of Goole, so that coal can be loaded into ships more cheaply than at any other port. It is also true that in 1900 the Grand Junction Canal Company spent nearly £50,000 in building a wide boat inclined lift to replace a flight of ten narrow locks on the Leicester branch of their system, but if they did, they failed to reap the benefit of this improvement by doing the same to the flight of seven locks on the same branch at Watford, so that this wide boat channel can still only pass narrow boats. What has been the result? The traffic never developed as it was anticipated it would do, and, in November, 1910, the Foxton lift was closed, and is now practically derelict. But worse still, in 1902 the Company found that the Watford narrow locks needed rebuilding, and this was done in good blue brick, but they were again built only 7 ft. 6 in. wide, so that this bottle neck still remains. Of course, all the canals have been maintained in more or less good order, and in some cases I believe the companies claim that there is now a greater depth of water than what they were designed for. This may be so, but still the fact remains that no general improvement has been carried out, and the canals are practically in the same condition as when constructed.

I must make one exception to this sweeping statement, namely, the Oxford Canal. This canal was built as a contour canal at a time when the tolls were levied on the length of channel traversed. It was, therefore, to the interest of the company that the distance between any two points should be as long as possible. I have been told that the boatmen used to be able to hear all twelve hours of the church clock strike in getting from one side of Banbury to the other.

Between 1829 and 1834 the Company decided to remodel the channel. The plan now on the screen shows in dotted line the original alignment of a portion of the canal, the solid line showing the new alignment.

The improvement was carried out between Longford and Wolfhampcote, the distance by canal being reduced from 37·6 miles to 24 miles, at a cost of £167,172. The particular cut-off at Rugby shown on the screen was 1,782 ft. long, replacing 3½ miles of the old line. It involved crossing a turnpike road and the River Swift by a three-arched aqueduct, the embankment being 25 ft. high.

The Royal Commission, in the statistical statements which accompanied the report, divided the canals into three groups, thus:—

	Miles.
Independent canals	2,565
Railway-owned canals . .	965
Railway-controlled canals .	218
Total	3,748

The railway-controlled canals comprise:—

(*a*) The Birmingham Canal System, controlled by the London & North Western Railway.

(*b*) The Sheffield & South Yorkshire Canals, controlled by the Great Central Railway.

Both these systems were taken over by the Canal Control Committee when it was instituted in 1917.

The above looks a very considerable length of waterway, but as it includes considerable lengths of navigable rivers, many short isolated lengths of canal and many miles which have been abandoned, the really serviceable total mileage is considerably less.

Thus, the total mileage given above may, for our present purpose, be rearranged as follows :—

	Miles.
1. Under Canal Control Committee	1,234
2. Managed by railways	965
3. River navigations	513
4. Small, isolated canals still working	154
5. Small navigations of no importance	539
6. Canals which have been abandoned	343
Total	3,748

From this it will be seen that over 880 miles have been abandoned, or are of no importance, leaving under 3,000 miles in efficient use.

In several appendices to this paper I have detailed the various channels which I have included in each of these groups, and in the cases of Nos. 1, 2, 3, and 4, have given statistics of the tonnage carried for the years 1888, 1898, 1905, 1913, 1918, and, in the case of the controlled canals, for 1919.

The map now on the screen shows the four routes known as "the Cross," which the Royal Commission proposed should be improved. It will be seen that the main idea was to provide through routes from the Midlands to the Humber, Mersey, Thames and Severn.

They gave much attention to the question of the capacity of the canals which were to constitute this "Cross." They evidently would have liked to recommend that they should be made capable of passing 300-ton boats, but on very detailed inquiry came to the conclusion that there would be insufficient water to maintain canals of that size, and eventually decided on 100 tons.

Much water has flowed down the locks since the Commission sat, and I am myself of opinion its recommendations for the construction of "the Cross" for 100-ton barges will never be carried out in their entirety, but that is no reason why a beginning should not be made, which, if it proved successful, could be extended later on.

The most important point is, whether Government is going to do anything towards forming a Waterways Board, as recommended by the Commission, so that the numerous small undertakings may be amalgamated and brought under a single administration.

I need not labour this point: the absurdity of short lengths of seven, nine, eleven and thirteen miles of canal, in a continuous through route, being under separate administrations, each with its own board of directors, secretary, or manager, and office establishment, is too well known to require further comment.

Then, although it may now not be practicable to carry out the ambitious scheme proposed by the Commission, I am convinced that there are certain minor improvements which might be carried out at no great expense, which would materially improve the efficiency of the waterways, both natural and artificial, and I should like to indicate a few of them.

Those which stand out prominently are the connection of the large industrial centres of Nottingham and Birmingham with the coast ports by a good waterway.

The map now on the screen shows, to a larger scale, the main through water routes of the country, those under the Canal Control Committee in solid lines, and those under railwway management in heavy dotted lines.

During the past summer, by the invitation of the chairman and directors of the Trent Navigation, I took a trip from Leicester to Newark by water. From Leicester to Nottingham, we were able to travel over the Leicester and Loughborough Navigations in the steam launch, but from Nottingham to Newark we were obliged to go in a small open motor boat, drawing 2 ft. to 2 ft. 3 in. of water, and even then we several times grounded on the bed of the river. Now there is not the slightest doubt that, for a comparatively small sum the River Trent can be made navigable for boats of a considerable size, say 500 tons, past Nottingham right up to the junction of the Loughborough and Erewash Canals. Think what it would be to see coastal steamers, possibly of special design, coming right up into the heart of this industrial area. At Sawley, where such an improvement would end, it would connect with the Erewash, Loughborough, and Trent and Mersey Canals, and the great railway system of the country, by all of which the produce brought in could be distributed by narrow boats or rail.

In this connection I ought to say that the Nottingham Corporation are under statutory obligation to improve the river between Nottingham and Newark, so as to pass boats of 100 to 120 tons. In 1916 the cost was estimated at £160,000, and the Development Commission recommended the Treasury that a grant of

£50,000 should be made, under certain conditions, out of the Development Fund. It was impossible to proceed with the work during the war, and the cost is now estimated at £300,000, but so far the Treasury has been unable to promise any financial assistance to the scheme, and it will be necessary for the Corporation to apply to Parliament for an extension of the time within which they are bound to complete the scheme. I venture to suggest that, for very little increased cost, the river might easily be made navigable for boats of 500 tons.

Again, consider the case of Birmingham. At present its only water communications with the coast are by narrow boats carrying 28 to 30 tons. The routes available are :—

(*a*) By the Worcester and Birmingham Canal.

(*b*) By the Dudley branch of the Birmingham Canal, the Stourbridge Canal, and the Stafford and Worcester Canal.

(*c*) By the Birmingham and Shropshire Union Canals to Ellesmere Port, distance about eighty-five miles.

(*d*) By several branches of the Birmingham Canal to the Trent and Mersey, and thence by that canal to Preston Brook on the Bridgewater Canal, distance about 100 miles.

The first route joins the Severn at Worcester, and is thirty miles in length. The second joins it at Stourport, and is much the same distance.

The construction of a big boat canal from Birmingham to the Mersey would, it must be admitted, be an extremely costly undertaking, and certainly may at present be considered beyond the range of practicable suggestions, but a connection with the Severn seems to me quite a different proposition.

Birmingham is only sixteen miles, as the crow flies, from Stourport on the Severn, up to which point boats with 100 to 150 tons can at present pass. Mr. Martin, in his paper at the conference already referred to, says, that with a comparatively small amount of dredging, boats of 300 to 500 tons could be passed to Stourport. The Commission contemplated widening the Worcester and Birmingham Canal to take 100-ton boats. This distance, as the crow flies, is twenty-three miles compared with sixteen to Stourport. It seems to me that it may well be a matter for investigation, whether it would not be better and more economical to cut a new canal, designed on modern up-to-date lines, possibly fitted with lifts, instead of locks, so as to conserve water, than to widen the existing canal, which in itself is a difficult matter, while still keeping traffic going. However, this is not a point which need be discussed at the present moment. The point of importance is, that boats of considerable size should be able to pass from the coast to a large basin at some suitable site outside Birmingham. This basin would be at the Birmingham Canal level of 453·0, so that produce might be loaded straight to, or from, the narrow boats of that large system. Surely, it would be worth spending a considerable sum on such a project, and considering the prosperity that has come to Manchester from its investment in the Ship Canal, I am somewhat surprised that so prosperous and enlightened a Corporation as Birmingham has not seen the direct and indirect benefits of assisting to finance such a project.

In advocating such a scheme I do not think that I should be right to ignore the fact that Mr. Samuel Lloyd, in his paper on Improvements in Canal Communication at the conference in 1888, stated that the following was then the calculated percentage of goods from Birmingham and the district shipped at the various ports :—

	Per cent.
From Liverpool	43
,, London	40
,, Hull	10
,, Severn Ports	3
,, South Wales	3
,, Harwich, Grimsby, etc.	1

I am unable to say whether the same percentages hold now. If they do, it would be a question for Birmingham merchants and traders to say whether they would not be altered if good water communication existed to the Bristol Channel ports.

If I were a younger man there is nothing I would like better than to have the job of finding a route from Stourport to Birmingham, and working out the details of the project, but I do trust that it will be done by someone. But if it is to be done, the sooner it is started the better. Prices will never return to those before the war, and Birmingham may well think regretfully of what it would have cost to carry out the scheme before the war compared with what it must cost if ever carried out in the future.

Another scheme of great importance, but which would not cost a very large sum, is the construction of a new entrance to the Sharpness Docks at Sheperdine about six miles below the present entrance. The object of this is to obtain an additional depth of nine feet of water over the sill, so that steamers may not be detained in the river for a sufficient depth of water, so often, or so long, as is now the case. The sanction of the Ministry of Transport has recently been given to this scheme being worked out

in detail, and when this has been done it is to be hoped that money will be found to carry it out; it would unquestionably be of great benefit to the town of Gloucester.

It seems to me that these three schemes would be a good beginning of improvement in our water communications, and would be ample to commence with. Personally, I am doubtful of the necessity for connecting the Midlands with the Humber, Mersey, Thames and Severn by 100-ton boat canals, and it seems to me that advocates of canal development, by asking for too much, have ended, and are likely to end, in getting nothing.

At the same time, I think a limited sum might usefully and economically be spent in improving the existing waterways. Thus, it would be sound to enlarge the canal between Birmingham and Braunston, so that wide boats, or two narrow boats abreast, could pass through the locks. This would make a uniform gauge from London to Birmingham. At present a narrow boat fitted with an engine and propeller leaves London towing another narrow boat behind her. They can both pass into the wide locks of the Grand Junction Canal side by side, as far as Braunston. From there to Birmingham the canals are narrow, and the carrier finds it better to send the self-propelled boat on alone and to provide a horse to tow the other, instead of detaining the former while the two boats are passed separately through each of the locks. This improvement would not be a very costly matter.

Whether it would be worth while widening the Watford locks on the Leicester branch and reopening the Foxton lift, must depend upon the development of canal traffic. At present there is no indication that it would be a paying proposition. There are other minor improvements that might, with advantage, be carried out, but it seems to me quite useless to take up your time detailing them until Government has decided what its policy is going to be in regard to the canals as a whole. On this subject the evidence of Sir Maurice Fitzmaurice before the Select Committee on Transport is worthy of careful attention.

There is one question which is very seriously affecting the canal carrying trade at the present moment, and that is the attitude of the labour unions.

The introduction of the forty-eight hour week and the refusal of boatmen to work at night has affected the canals and carriers possibly more than any other industry. The manager of the Aire and Calder Canal recently told me that before the war a train of empty boats would travel by night from Goole to the colliery, load next day and return to Goole the following night; unload next day and again return to the colliery at night. Now the men will only work by day, with the result that it takes three days—72 hours—to do the trip, instead of a day and two nights—36 hours.

But the industry is likely to be affected in other ways. One of the clauses in the recent Peace Treaty provides that children under the age of fourteen shall not be employed in any industry. The labour union leaders have also recently approached Government with a view to prohibiting living on boat, at all, either by men, women or children. They urge that the accommodation is too small, insanitary and unhygienic; they admit that the families are content, and will resent being compelled to abandon living on their boats, but state that it is necessary for their social betterment. They also say that a very high percentage of children are drowned, and that they cannot be properly educated. As regards the first of these points, I can only say that my own observation is that I have seen no healthier families anywhere than those on the canals, and this is borne out by the pictures exhibited on the screen. Personally, I do not think there can be any comparison between the healthiness of canal boat family life and that of a family brought up in a city, I will not say a slum, because we all hope these will be done away with in time. The excessive loss by drowning is denied by the people most concerned, namely, the boatmen themselves. The question of education is, of course, a difficult one. The present system is that children on canal boats are given a travelling ticket permitting them to attend school at any place where the boat is tied up. No one can pretend that this is a satisfactory arrangement, and the education obtained must indeed be elementary. I believe it is a fact that the standard of education amongst canal boat workers is low, but in my opinion education is not everything in this life, and a lower standard of education with better physical fitness may in the end give the most useful citizen.

I have not made exhaustive inquiries as to what proportion of boatmen live on their boats with their families. I understand that on the Shropshire Union Canal, 90 per cent. of the boats are in charge of a man and his wife, and nearly all have young children on board.

The director of the Anderton Company, who own and work eighty-three boats, informed me that of their boatmen, one-third own houses and live in them when not actually working on the boats; one-third own houses, very seldom occupy

them, but use them mainly as headquarters to store their belongings; one-third live entirely on the boats.

I am unable to say, without further inquiry, whether these proportions would apply generally to other carriers. Some years ago a census of the canal and river population was taken, with the result it was found that of 60,000 employees, 10,000 men, 4,000 women, and 2,000 children lived on the boats.

There can be no doubt that children are of the very greatest service on a canal boat. It is no uncommon thing for a man and his wife, with the aid of their children, to work two boats. The man takes charge of one and his wife of the other, the children guiding the horse, who probably knows them well, and is obedient to their orders. One case has been reported to me where a man and his wife, with nine children, regularly work three boats. The four eldest of the children are respectively eighteen, seventeen, sixteen and thirteen years of age, the one of sixteen being a boy and the other three girls. The whole family lives on the three boats. If children are to be allowed on boats at all, it is difficult to see how parents can be prevented from using them in work suitable to their strength and ability; anyone travelling over the English canals cannot but be struck by the appearance of the children, fine and healthy with rosy cheeks. They are, in my experience, well fed and clean. I am infomed that to prevent young children under the age of fourteen being initiated into the intricacies of canal transport would be disastrous. If young boys and girls are not allowed to assist their parents, there is every likelihood that, when they attain the age of fourteen, they will not take up work on the canals at all, but will find work in the towns.

The rules at present governing the residence of children in canal boats are those contained in Part III. of Local Government Regulation No. 7,768 of March 20th, 1878. I need not recapitulate its provisions here, but it will be seen that they consist entirely of rules fixing the number, age and sex of persons who may be allowed to dwell in a canal boat having regard to the cubic space, ventilation, separation of the sexes, healthiness, and convenience of accommodation of the boat—subject to these rules, there is no limit to the number or ages of the children that may reside in a boat.

In conclusion, I may say that it is certain that any order prohibiting living on boats would apply to a very large number of people, and would very seriously affect the canal carrying trade. Indeed, it is difficult to see how long-distance traffic could be continued at all, if boatmen are not to live on their boats. It would be practically impossible to provide rest houses for them to stop in at night, for a man cannot always be certain where he will get to, nor would it be safe to leave valuable cargoes unprotected at night by the side of a canal. There is, of course, no certainty that action will be taken in the matter by the Government, but the application of the union leaders shows what is moving in their minds, and may very greatly determine the future of canal transport.

In this connection, too, I may state that one of the items in the national programme of the National Federation of Transport Workers, which has recently been put forward and is now under consideration of the Ministry of Labour, is that two adult males should be in charge of every boat. As, at the same time, they also demand a wage of £4 10*s.* per week for the captain, and £4 5*s.* for the second man, for an eight-hour day, with overtime at time and a half or double time for any hours in excess of eight per day, it will be seen that the expense of carriage by canal may render that means of transport prohibitive.

I regret that my paper should not depict the canals of the country and the prospects of canal carriage in a more favourable light; but there is no gainsaying the fact that at the present moment most, if not all the canal companies are bankrupt, and that unless something is done to revivify them they must eventually close down, which, I venture to believe, is unthinkable.

That the above statement is no exaggeration is shown by the fact that there were only eight of the controlled canals whose receipts in 1918 exceeded their working expenses, while on the whole of the controlled canals the deficit amounted to £240,774. This without the payment of debenture or any other interest to shareholders. As expenses in 1919 have still further increased, the deficit in that year will be much greater, as indicated by the increase in the Government contribution. I have not considered it necessary in this paper to refer to the question of the increase in railway freight rates and their effect on the canals. The matter has been carefully studied by a Committee, of which I am a member, at the Ministry of Transport. I may, however, say that increases in the canal tolls and freights, similar to those introduced on the railways from January 15th, would not be sufficient to put the canals, as at present administered, in a sound financial position.

DISCUSSION.

The Chairman (Mr. Neville Chamberlain, M.P.), in opening the discussion, said the paper was very interesting, informing, and carefully prepared. He was much gratified at being invited to preside at the meeting, because for a good many years he had made it a practice to seize any opportunity that presented itself to talk about canals to anyone who would listen to him. Although the intervention of the war made it necessary to shut down the activities of the Waterways Association, of which he had the honour to be Chairman, yet he might say that at the beginning of the war the Association had made some substantial progress in educating not only public opinion but also Departmental opinion upon the advisability of taking the subject of canals a little more seriously than had been done before. With regard to the present situation of canals and inland waterways, the author had concluded his paper with a picture of the present financial position of canal companies which was melancholy, but, he was afraid, not in the least exaggerated. That was not the fault of the companies, but was due to the circumstances of the war. The Government, by artificially keeping down the railway rates, had made it impossible for canals, which were not subsidised to the same extent, to compete with the railways, and consequently traffic had been driven off the water and on to the rails. For the most part nothing whatever had been done to the canals since they were constructed to improve them and to enable them to take advantage of modern advances in engineering science, and they had to compete with railways on which some of the finest brains in the country had been perpetually at work until they had been brought to a high pitch of efficiency. Therefore it was absolutely impossible to suppose that for many years to come canals could be on an equal footing with railways. This country had got to make up its mind whether it was going finally to abandon the prospect of inland water carriage altogether, or, if it was not prepared to take that view, then it must be willing to foot the bill and to treat the matter, not as a commercial proposition, but as a preparation for an improved state of affairs, when canals would be brought up to a condition comparable with that of railways and would be able to do for this country something that might fairly be compared with what canals on the Continent were doing for Continental countries. The author said in his paper that he did not think it was of much use to go into details of minor improvements until the Government had declared what its policy was going to be with regard to canals as a whole. That particularly affected him, because two days ago in the House of Commons an announcement was made by the Parliamentary Secretary to the Ministry of Transport that the Minister intended to set up a Committee to inquire into the possibility of minor improvements to canals, and that he hoped to have his (Mr. Chamberlain's) assistance as Chairman of that Committee. He regretted somewhat that that statement was made, because it was entirely premature. The fact was that he took precisely the same view of the question as the author took. In his opinion it was necessary first of all to have a definite policy decided upon, and only then would it be worth while to consider what minor improvements could be carried out in canals. Under the Transport Act powers were given to the Minister of Transport to take possession of the canals for a period of two years, and those words "take possession" had a technical meaning in the Act. They did not mean necessarily to buy up the canals, but they meant to take control of them. If the Minister of

Transport took possession of the canals he had power to do a good many things. He could close such parts as were at present useless; he could give grants and make small improvements; he could have the canals dredged, many of them having got very badly silted up during the war; he could enlarge locks; and he could set up a Committee to control the whole of the canals, railway-owned as well as independent, and that Committee, by co-operation with the Railway Executive Committee, could see that rates were so arranged as to divert to the canals the heavy and bulky traffic which they were particularly well fitted to carry and which at present was congesting the railways. During those two years the Minister of Transport could do what it was laid down in the Act he was to do, *i.e.* he could consider and formulate a permanent policy with regard to the inland waterways of the country. If he did what he had the power under the Act to do, *i.e.* if he took possession of the canals, he would come up at once against the very difficult problem of what was to be the ultimate ownership of the canals. The author had pointed out that at the present time canals were owned by a multiplicity of authorities; short lengths of comparatively few miles, forming parts of a through route, were under the direction of different Boards. If during the period of two years the Minister were to carry out improvements upon any of those short lengths, the question would arise at the end of that time, supposing he intended to hand that canal back to its original owners, what was to be done about the improvement—who was to pay for it, who was to have the benefit of it? The railway companies, too, would have something to say if the railway-owned canals were taken from them for the period of two years and were then to be returned to them. Therefore he thought it was absolutely necessary that the Ministry of Transport should make up its mind quickly as to what was to be the ultimate ownership of the waterways. He did not hesitate to say that in his opinion it had got to be public ownership. He liked to see private enterprise developed to its utmost extent, and developed as much as possible in the direction of carrying upon the canals, but he considered that the economic return upon money expended in the maintenance and improvement of the waterways themselves was so doubtful that, seeing it was in the interest of the whole community that the waterways should be maintained, the cost should be borne by the community and could not be expected to be borne by any private enterprise. Just as the roads of the country were maintained by the community and put at the disposal of anyone who chose to run a vehicle upon them, so he thought the canals also ought to be kept and maintained at the public expense, but of course always subject to the payment of tolls. If that policy were adopted and declared, people would know where they were and what they were working towards. The two years given to the Minister would not be any too long for having the whole subject investigated as to what large major improvements should be carried out, such as some of those mentioned by the author, where through routes, and especially river routes, offered a prospect of considerable benefit to the industries of the country. There would be questions connected with those large improvements which had never yet been thoroughly thrashed out. How were they to be financed? How were the contributions to be made by the State or by the great local authorities, which stood particularly to benefit by the improvements, to be assessed? What was going to be done, for instance, with the landowner who had a frontage upon the present route, a frontage which would be immensely improved in value if the widening of the canals took place to the 100-ton standard? Was he to have the whole benefit of that, or was some portion of it to come to those who were finding the money for the improvements? He believed those problems could be solved, but they had never yet been given to anybody to solve. He would like to see a Committee set up to consider what would be the best policy to follow in respect to those large improvements, and, by the time they had investigated the whole subject and made their report to the Minister, it was at any rate conceivable that the financial position of the country would have so improved as to make it possible to put before Parliament a scheme which would certainly require the expenditure of a considerable sum of money—an expenditure which at the present moment would have very little chance of acceptance by the Government or by the House of Commons. Briefly, he believed the first action of the Minister of Transport should be to take possession of the canals; that he should announce his policy at the earliest possible moment, first as to whether the canals were to remain an integral part of the transport system of this country, and, secondly, as to what was to be their ownership; that he should set up a Committee to operate and control the canals of which he took possession, to recommend to him the points on which a comparatively small expenditure would produce the best result; and that he should have an Advisory Committee set up to investigate and to report to him in due course upon the policy to be adopted as to major improvements. If those suggestions were carried out, he thought the problem would have some substantial prospect of solution in the near future.

Sir John Eaglesome, K.C.M.G. (Aire and Calder Navigation), said the author had written a very interesting paper on a subject that was usually regarded as an uninteresting one, but he had forgotten to mention the part he himself played in connection with canals during the

war, first of all as Chairman of the Southern Sub-Committee and then in organising and successfully working a system for training men belonging to the Transport Workers' Battalion, which was afterwards introduced all over the country. Later on the author succeeded Sir Maurice Fitzmaurice as Chairman of the Canal Control Committee, which might be regarded as a model to some other Government Controls. Personally he thought the chief thing the matter with canals was that they were not sufficiently understood. People went along in a train and saw a barge with a horse pulling it, and that reminded them perhaps of a shady walk somwehere, or, as he heard the Chairman once say, of a rustic angling club. If people ever went so far as to talk about canals they said: "I suppose canals are out of date," or, "Why do not you make more use of your canals, as they do on the Continent?" It was no good making that sort of comparison —one might as well compare an English river with the Mississippi, which had 14,000 miles of navigable waterway. The Rhine carried 40 per cent. of the whole of the water-borne traffic of Germany, the four chief rivers in Germany carried 80 per cent. of the whole, and the Seine carried 26 per cent. of French water-borne traffic; but this country was an island with a backbone running down the centre that took a lot of climbing, although where the country was flat, as it was in some parts, water transport was very suitable. Another point to be remembered was that there was not a single manufacturing town in this country more than seventy miles distant from a sea port. That fact gave rise to two schools of thought. One said: "The sea is very close and there are plenty of railways—what more do you want?" The other said: "The sea is close; why do not you develop along the natural lines of drainage and bring it closer still?" That was done once, in the case of the Manchester Ship Canal; the shareholders made nothing out of it, but Manchester improved and developed greatly in consequence. That happened in a good many other cases where people who did not usually patronise canals made use of them for keeping railway rates down. There were two points that he would like to bring before the meeting with regard to English canals. The first was that where the country was suitable for a canal that canal would be successful; but many of the canals in this country were built when they had to compete with pack animals or a primitive kind of wheel transport; then the era of steam began, and workshops and factories were built which all wanted water, and therefore they were built with their walls right on the canal bank and were all dependent on the canals now for water even. Those places had a certain amount of advantage, because it was obviously better to take coal out of a barge right into the works than to take it out of a railway wagon in a yard, even if it only had to be wheeled fifty yards. Many of the canals in this country were like one in North Wales that he once travelled along in a comfortable barge with no traffic to interrupt the view; the other kind of canal could be seen at Birmingham, Manchester or Liverpool, where all the heavy work was done, and that was the kind of canal that the average man did not see. The second point he wished to mention was the question of improvement. The canals were built with different draughts, different sizes of locks, and different gauges, by men of genius who had a great many difficulties to contend with; they had not large funds, and they had difficulty in the kind of country through which the canals travelled. Therefore the question now had to be considered of improving them. Any improvements would greatly benefit the country, but if the Minister of Transport said, as he once did, that every transport undertaking had got to stand on its own legs, he would find it difficult to obtain a direct return from the capital expenditure involved in the improvements. If ever a town deserved a good canal, that town was Birmingham. Seven million tons of traffic were carried on the Birmingham Canal every year before the war, and he was told that the goods traffic per ton mile on the Birmingham Canal was actually heavier than the goods traffic per ton mile on the London and North Western Railway. With regard to a canal being suitable if it was in the right kind of country, that applied particularly to the canal that he knew most about, the Aire and Calder, which was quite different from the derelict and old-fashioned canals that people were apt to think of. It started at the junction of the Trent and the Ouse, and 2,000-ton boats could go up it to Goole, where there was accommodation for about eighty ships. From Goole there was a canal 70 ft. to 90 ft. wide, navigable by boats of 7½ ft. draught, which allowed the large barges which navigated the rough water of the Humber to go through the port of Goole and right up to Leeds and Wakefield. The canal had got the system of compartments which the author had described, like a railway train, with couplings and buffers and pulled by a tug, like an engine. Mr. Dunwoody had produced figures showing that in France and Germany before the war more than one-third of the water-borne traffic was coal and more than one-quarter was building material. That was the sort of traffic that canals ought to have, and this country might well follow the example of the Continent in that respect. The ideal arrangement was to have a canal on one side of a works and a railway siding on the other, and to bring up the heavy material, such as coal and ore, by water, and the material that required to be brought quickly by rail, and to send away the finished products by rail. Unfortunately that ideal combination

had very often in the past resulted in a senseless rate-cutting competition, with the evil result occasionally of cutting down the wages of the lower-paid operating staff. The dock and navigation trusts that had done such great service to the nation in the past were now, as the author pointed out, not in a position to pay their way, except by raising the tolls and by increasing traffic facilities. But increased traffic facilities meant increased capital expenditure, and most of the companies were not in a position to borrow. No one was going to lend money at 2½ or 3 per cent. when he could get gilt-edged securities at 6 per cent. It would be little short of a national disaster if those trusts were compelled to curtail their services, to reduce their maintenance, and to suspend all developments for want of a little support during the period of stress through which they were now passing.

Mr. R. F. de Salis (Grand Junction Canal) congratulated the author on the very interesting paper he had read. There was one criticism he would like to make on the author's remarks concerning his own Company, as he was rather severe on the Foxton lift and Watford locks. The fact was that the Company bought the Leicester canals primarily for their valuable water supplies, and then, as a second string, tried, by dredging, to put them into a fit state to carry traffic. The Company were induced, by the hope of increasing traffic from the Midlands, especially coal traffic, to build the Foxton lift, which would carry two narrow boats or one wide boat or barge, but they found the traffic did not come. In fact, one canal, the Nutbrook Canal, which should have been one of the principal feeders, had been allowed to become derelict, and they also found that the canal tunnel connecting the Erewash and the Cromford Canal was allowed by its owners to become impassable. They therefore felt they could not ask their shareholders to put up a lift at Watford, as was originally proposed, and as they found that practically all the traffic was carried in narrow boats they felt that to widen the Watford locks would have been waste of money until they saw their way to obtain more traffic, of which he was sorry to say, there was no prospect at present. The author had spoken of the necessity for amalgamation of canals. That was so obvious that the natural criticism must be: "Why on earth have not these canals amalgamated before?" But the canals in the south found themselves faced with the question of parochial rates. At present they were rated as agricultural land, but directly they went to Parliament for an Act, which was necessary for amalgamation, the parochial authorities wanted to put them on the basis of railways and rate them on their trade. His own canal did make an arrangement to amalgamate with the Warwick Canals some years ago, and that would obviously have been a great improvement and would have caused the enlargement of the locks on the Warwick Canals, which were narrow, while those on the Grand Junction Canal were wide. That scheme had the warm support of the late Mr. Joseph Chamberlain, but he was unable to overcome the rating difficulties. If they had gone on with the Bill and changed their form of rating they would have lost more than they would have gained by the amalgamation. That was another argument for some form of Government or central control. With regard to the general question of canals, the view put forward by the author and the Chairman was, he thought, the view of all those who were expert in canal management. With the present heavy demands of labour, both in money and in concessions, it was utterly impossible for either the canals or the traders on the canals to carry on in competition with other forms of transport. If the rates were raised to anything like the railway level, that would be a mere drop in the bucket; it would not enable the canals or the traders to live, and the natural consequence was that if the canals were not subsidised in some form or other they would to a considerable extent become derelict. There were certain sections of the canals which would pay and would be kept going as commercial concerns, but the Government had now to decide whether they were going to look on canals from the commercial point of view, and if a canal or a section of a canal did not pay, to let it become derelict, or whether they were going to look on the subject of canals as a national question and, either by taking them over or in some other way, keep them going with possibilities of improvement where money could be usefully spent.

Sir James Bruton, M.P., wished to congratulate the author on his singularly capable address, and to thank him for the very clear and interesting slides that he had shown. He drew the attention of those present to the fact that in 1913 there was traffic to the extent of 32½ million tons carried on the inland waterways of this country, representing some 4,500,000 truck-loads. If the recommendation of the Canal Commission alluded to by the author had been carried out during the war, an enormous advantage would have accrued to the country and a great saving of railway traffic would have been brought about. If the same support and encouragement had been given to canals as to railways, it would undoubtedly have had a good effect. No encouragement, however, was given to canals; in fact, it was not until 1917 that any attempt was made to protect their men. By that time a large number of them had gone, and it must be borne in mind also that boats were not being built and there was the greatest difficulty in getting boats repaired. Altogether the traffic on the inland waterways had decreased

during the war by 33 per cent. Those interested in canals looked to the Chairman as their leader in the House of Commons to press forward the question of waterways, and they were sure that if the Minister of Transport appointed a Committee, as suggested, it would be a step in the right direction.

Colonel J. A. Saner (River Weaver Navigation) said that, like the other speakers, he desired to congratulate the author on the way in which he had brought the subject of canals before the meeting. It was not at the present time a very happy thing to be connected with canals and waterways. He had personally taken part in the Conference convened by the Society of Arts in 1888, and he was sorry that more progress had not been made up to the present, but there were many difficulties in the way. One was the fact that the canals were now very much as they were a hundred years ago—they had not been brought up to date. People did not take into consideration (or at any rate they had not up to the time of the war, when they suddenly became aware of the fact that it was necessary to be economical with coal and with other forms of energy) that carriage by water was more economical in regard to coal and petrol and other forms of energy than carriage by rail. That was one of the most important points that ought to be taken into consideration by the Minister of Transport when he was deciding whether to resuscitate the canals and to take them over for the benefit of the nation as a whole. He had been Engineer to the River Weaver Navigation for about thirty years, and he had always wondered why it was that he could not persuade people to improve the waterways, especially the Weaver, further inland. The Trent and Mersey Canal was connected with the Weaver and also with the Mersey, and boats could come up the Weaver with anything up to 400 tons on board. They came up to Winsford, which was forty miles from Liverpool, and at Anderton there was a lift worked by electric power, which raised the small canal boats up into the Trent and Mersey Canal. At the present moment paraffin-driven boats went up the Anderton lift and to Middlewich, six miles beyond Anderton, and then they could go no further, because the locks were small seven feet wide locks up to Stoke, which could only take 25-ton boats. If those paraffin-driven boats, which could carry seventy tons of material at an expenditure of three-quarters of a gallon of paraffin per mile, could go up to the potteries at Stoke, a very great improvement would be effected and the result would be commercially successful. Up to the present there had been two owners of the waterway from the Mersey to the Potteries—the North Staffordshire Railway owned part of it and the Weaver Trustees the other part—and they had never come to any arrangement to work it mutually or to improve it. Those were the sort of things that would have to be considered when the policy with regard to canals had been determined. It was no good carrying such materials as coal and limestone and bricks by rail, taking them at the rate of forty or fifty miles an hour and then allowing them to lie in the contractor's yard for three or four weeks before they were wanted. If they were carried by water at five miles an hour they would get to their destination in time, without the expenditure of so much energy. He hoped the experience of the war would teach the people of this country to conserve the energy that they had in the country. He also hoped that under the new Ministry of Transport the canals would be worked more economically and more harmoniously, and that the difficulties which had arisen through the competition of the different Companies would be overcome.

Mr. G. R. Jebb, M.Inst.C.E., said no one could have appreciated the paper more than he had done. When he heard that a Committee was to be appointed "to consider what development of canals and waterways was practicable, having regard to the financial position of the country at the moment," he was afraid that the author and the Chairman might possibly recommend a resuscitation of the larger schemes referred to by the Royal Commission, which he had always opposed on economic grounds, and he had come prepared to state his arguments against such schemes, but after listening to the moderate and temperate suggestions made in the paper, and the remarks of the Chairman, he decided to say nothing about the larger schemes. It would, however, be necessary that any recommendations that might be made by the new Committee, and particularly any that might have reference to the making of a new canal from Birmingham in the direction of the Severn, should have very careful consideration, with the view of ascertaining whether they could be justified, having regard—among other things—to the financial position of the country.

Mr. R. B. Dunwoody (late Secretary, Canal Control Committee) said he was pleased to have had the opportunity of listening to the paper, which had brought out a number of new points. The Chairman had stated very clearly the exact position of the question at the present time. The Minister of Transport had to decide what was to be done; he could advise the Government to carry out the recommendations of the Royal Commission or some other scheme. If the report of the Commission was read carefully, it would be seen that it did not say that the "Cross" scheme should be carried out at once—what it recommended was that a Board should be set up which should have the power to go into the whole question afresh and make recommendations to the Government as to what should be done. Nothing could be done until

Parliament passed new legislation, and therefore to say that the Royal Commission recommended the Government to go ahead at once and carry out the scheme was not exactly stating the facts.

On the motion of the CHAIRMAN, a hearty vote of thanks was accorded to the author for his interesting paper.

MR. PRESTON, in reply, desired to say, with reference to Sir John Eaglesome's remarks, that if he had had any success as Chairman of the Canal Control Committee it was entirely due to his predecessor, Sir Maurice Fitzmaurice, who laid the foundations of the canal control. He had only carried on, with the aid of Mr. Dunwoody until quite recently, what Sir Maurice had begun. In conclusion, he would like to repeat one remark which he made with reference to the present state of the canals when Mr. Dunwoody read his recent lecture on canals at the Institution of Civil Engineers. Could one imagine what would be the present state of motor traffic if the roads of England were in the same condition as they were before Macadam lived, and if they had been dependent for development and improvement on the turnpike tolls? Could motor traffic ever have developed under those circumstances? Even after Macadam had made his beautiful metal roads, directly the motor came they were inadequate and tarred roads had to be constructed. Yet the canals were in the same condition now as when they were built.

The meeting then terminated.

CORRESPONDENCE.

CAMOUFLAGE.

With reference to the paper on "The Dazzle Painting of Ships" I send you a note on various meanings of "Camouflet" or Camouflage."

"Camoufle" was an old French word meaning smoke.

"Dictionnaire Usuel de la langue Française," par A. Bourguignon, Paris, 1877, has the following: —

CAMOUFLET, s.m. Fumée épaisse qu'un souffle malicieusement au nez de quelqu'un avec un cornet de papier allumé. Fig. et Fam. Sanglant affront.

"Dictionnaire Historique d'Argot": Loredan Larchey, Paris, 1880, has the following: —

CAMOUFLER. Déguiser. (Beauvillier.)

And in the Supplement:—

CAMOUFFLÉ. Homme portant fausse barbe. (A. Pierre.) De Camoufler (se): se déguiser.

CAMOUFLER LA BIBINE. Falsifier (mot à mot: déguiser) la bière.

The "Penny Cyclopædia," 1836: —

CAMOUFLET or STIFLER, in military mining, is a small charge of powder sunk in the wall of earth between two parallel galleries, in order that by blowing the earth into one of them to suffocate or cut off the retreat of the miner who is at work in it.

"Camouflet" or "Camouflage" was used by the criminal classes in Paris, and I believe meant "to disguise or deceive," and it is clear that this is what was meant by "camouflage" during the war.

C. J. SEYMOUR BAKER.

OBITUARY.

CHRISTIAN WILLIAM LAWRENCE, D.L.—The death has occurred at his residence, Sandywell Park, near Cheltenham, of Mr. Christian William Lawrence, in his eighty-fifth year. He entered the diplomatic service in 1859, and, among other offices, he was Secretary of the British Legation in Stockholm, and British Minister to Ecuador. The last post he held from 1883 to 1890, when he retired. Mr. Lawrence was a magistrate and Deputy Lieutenant for Gloucestershire, where he was a considerable landowner. He was elected a member of the Royal Society of Arts in 1904.

GENERAL NOTES.

RECLAMATION OF THE PONTINE MARSHES.—A company has recently been formed, according to the *Anglo-Italian Review*, for the reclamation of the famous Pontine Marshes. The company's policy is based on drainage and canalisation of the mountain torrents which, after foaming down the gorges of the Lapini Mountains, spread over the plain irregular masses of rock detritus, thus forming a *terai*, which the absence of defined channels for the drainage of the water turns into dangerous breeding-grounds for the Anopheles mosquito. Canalisation is now in rapid progress, and as soon as the water is confined within banks it becomes possible to deal with the shrub-covered land. This is done with the aid of British "Fowler" steam ploughs, the only type found powerful enough to deal effectively with the strongly rooted brushwood. This levelling and aeration of the soil is expected to exterminate malaria in a very short time.

FLAX CULTURE IN RUSSIA.—The *Textile Mercury* of December 6th, 1919, contains some interesting particulars of the efforts which are being made by the Flax Growers' Association to extend the production of flax in Russia. Whilst the average yield of flax for the years 1903-1914 was 363,000 tons for Russia, the yield for all other European countries only totalled 116,000 tons. On the other hand, the average yield to the acre for Russia was only 300 tons as against 400 to 700 tons to the acre for other countries. The Association is now organising the peasants on co-operative lines, to restore and extend flax cultivation in the country.

Journal of the Royal Society of Arts.

No. 3,514. VOL. LXVIII.

FRIDAY, MARCH 26, 1920.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

INDIAN SECTION.

FRIDAY, MARCH 19th; THE RIGHT HON. LORD CHALMERS, G.C.B., LL.D., in the chair. A paper on "The Indian Currency System and its Developments" was read by SIR WILLIAM S. MEYER, G.C.I.E., K.C.S.I., Financial Member of the Council of the Governor-General of India, 1913–18.

The paper and discussion will be published in a subsequent number of the *Journal.*

FIFTEENTH ORDINARY MEETING.

WEDNESDAY, MARCH 24th; SIR HENRY TRUEMAN WOOD, M.A., Vice-President and Chairman of the Council, in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Bellamy, F. S., Teneriffe, Canary Islands.
Board of Trade, Great George-street, S.W. 1.
Cleghorn, Miss Maude Lina West, F.L.S., Calcutta, India.
Colvin, Sir Elliot Graham, K.C.S.I., London.
Durham, The Right Hon. the Earl of, K.G., G.C.V.O., London.
Green, Frank Ernest, Uxbridge.
Griffith, John Henry, Llanbedr, Merioneth.
Jones-Keith, W., Rouen, France.
Keller, Miss Frances A., New York City, U.S.A.
Mutch, Stanley Robert, M.A., London.
Osborne, Charles Haddon, J.P., Luton.
Pole, Major D. Graham, London.
Randell, Charles Edmund, London.
Sankey, Charles Herbert, Chislehurst, Kent.
Sutherland, Daniel Manson, Teddington.
Taylor, John Brown, Dundee.
Wren, Captain Frederick, M.G.C., Bedford.

The following candidates were balloted for and duly elected Fellows of the Society:—

Bond, Colonel Charles John, C.M.G., F.R.C.S., Leicester.
Gane, Charles, London.
Kahn, Otto H., New York City, U.S.A.
Kerfoot, Thomas, Gee Cross, Cheshire.
Murray, Victor F., B.Sc., London.
Pullin, Victor Edward, London.
Rawson, Thomas Gregory, Borrowash, Derby.
Reed, Clifford, Nelson, Lancashire.
Robarts, Harvey B., M.A., F.R.G.S., London.
Roberts, Joseph Henry, Rotherham, Yorks.
Tagore, Raj Kumar Nawab S. K., Calcutta, India.

A paper on "Industrial Lighting in its relation to Efficiency" was read by MR. LEON GASTER, Hon. Secretary of the Illuminating Engineering Society.

The paper and discussion will be published in a subsequent number of the *Journal.*

COVERS FOR JOURNALS.

For the convenience of Fellows wishing to bind their volumes of the *Journal*, cloth covers can be supplied, post free, for 2s. each, on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

ELEVENTH ORDINARY MEETING.

WEDNESDAY, FEBRUARY 25th; THE RIGHT HON. SIR JOHN TUDOR WALTERS, M.P., in the chair.

THE CHAIRMAN, in opening the meeting, expressed his regret at the unavoidable absence of Sir Robert Horne, who was to have presided, and who took a close personal interest in the subject of the paper and in the work that Mr. Currie had been doing for some time past. He had personally had an opportunity of seeing something of the urgent necessity for industrial training in the work he had been doing at the Ministry of Health for the last two years. A great deal more trained and skilled labour was required by the Ministry than was available in the country at the present time, and if the scheme Mr. Currie was responsible for could so extend its operations as to provide the Ministry of Health with some trained carpenters, bricklayers, slaters, and plasterers, there might be a remote possibility of getting some houses built some day. The problem which existed before the war had been accentuated by war

conditions, and it surely could not be wise, from the standpoint of national health and efficiency, that so large a portion of the population should be inadequately trained or not trained at all in some useful technical art or handicraft. Many thousands of men during the five years of war conditions lost the ordinary opportunities of receiving industrial training, and it was the duty of the State to see that, in such measure as was possible, it made up for those lost opportunities. It was lack of education from the very commencement of life that was our most serious handicap. He believed there were tens of thousands of men and women who were willing and anxious to be trained, and if, by wisely directed State operations along the lines Mr. Currie and his colleagues suggested, they could be brought within the sphere of training it would be a great advantage to them. If they had abundant opportunities of receiving a skilled training it would enlarge their outlook, make their work less monotonous, and enable them to discharge larger and more important functions in the State, and it would be of benefit to all concerned.

The paper read was—

INDUSTRIAL TRAINING.

By JAMES CURRIE, C.M.G.,
Ministry of Labour (Training Department).

Industrial training of the type for which the writer of this paper has been to some extent responsible is the product of the war.

In the sense in which it was used during the war period it meant, speaking roughly, the training of men and women, as quickly as possible, to perform certain definite operations required in making munitions. When the war was over there remained the problem of finding new occupations for discharged and disabled soldiers who, unfortunately, were unable to follow their former trades, and not unnaturally the machinery which tackled the munition problem is now largely employed with the problem of the soldier.

The problems are, of course, not identical, the object of munition training being to train a specialist in one or two operations in the minimum period of time, that of the latter to turn out a skilled workman by means of intensive training in an abbreviated period.

The magnitude of the task imposed on the Training Department may be best gauged by the fact that it is estimated that a sum of at least twenty-two millions will be spent on this work during the next two or three years, and that from sixty to eighty thousand disabled men will be trained for the numerous trades in the various industries.

The particular schemes adopted have not been framed by Government; they represent the labour of joint bodies of employers and workmen, called National Trade Advisory Committees, which, in many cases, are affiliated to the newly constituted National Joint Industrial Councils.

Schemes have been prepared by practically all the principal English trades. For purpose of illustration I would refer to two such—engineering and building. In my opinion these are extremely important and interesting documents, as this is really the first occasion when the trades themselves have been responsible for the framing of what are, in effect, elaborate schemes of training for industry.

At this stage it is perhaps worth while to trace the evolution of the movement in some detail. In 1915, when the Ministry of Munitions was formed, the scarcity of skilled and semi-skilled labour was not among the least of the difficulties with which it was confronted. Dr. Addison, who at that time was in charge of the labour side of the Ministry of Munitions, conceived the idea that it might be possible to utilise the technical schools of the country to assist in meeting the great and growing scarcity of semi-skilled workmen, leaving the skilled workmen free for the more difficult operations. A small section was established in the Labour Supply Department of the Ministry of Munitions to organise the efforts of the local education authorities. Beginnings were made on a small scale, but it was not until towards the end of 1916 that the seriousness of the situation became manifest to every one, notably on account of grave labour shortage in connection with aero engine production, and Mr. Montagu, then Minister, gave categorical instructions that the situation was to be thoroughly explored. One of his last letters on leaving the Ministry in 1916 was as follows:—

"If I had remained here, I should have asked for an immediate investigation of the possibilities of increase, and I would recommend this topic as worthy of the immediate attention of those responsible in the Ministry of Munitions.

"I recognise the difficulties about the machinery, but I feel that even recalcitrant local bodies and private institutions, even the grave objections to considerable training in factories which are also producing, must be overcome, and we must make arrangements to turn out semi-skilled and skilled men and women at a far greater rate than anything yet achieved."

From that time progress was rapid, and training schemes assumed definite shape.

So far as the Ministry was concerned training was conducted under three categories :—

1. Training in technical schools.
2. Training in instructional factories.
3. Training in instructional bays attached to particular works.

Technical schools were under the management of local education authorities, financed and inspected by the Ministry of Munitions. Instructional factories were under the direct control of the Ministry. Instructional bays were under the management of individual firms, sometimes financially assisted by the Ministry, sometimes not. In no case was help given unless the trained product was mobile and available for work anywhere in the United Kingdom.

The development of training proceeded apace in proportion as the production engineer, with his gospel of manufacture on specialised repetition lines, gained general acceptance.

Prior to the outbreak of the war he had not, generally speaking, found convinced listeners, but the development of machine tools and the setting up of enormous establishments for the manufacture of articles for which there was an unlimited demand, revolutionised both technical and public opinion.

The history of the training movement, so far as it was successful, consisted—(*a*) in the acceptance, by the training section of the Ministry itself, of the production idea as the basis of their operations ; (*b*) in their education of the local education authorities along the same lines: this involved the equipment of the schools with modern machinery which would render actual production possible ; (*c*) in a similar process of evolution taking place among works managers and manufacturers.

At first the section fumbled rather blindly, preaching a gospel it half believed to a limited number of somewhat sceptical adherents. It owes its technical salvation to some half-dozen production engineers—to Mr. Purdy and Mr. Buscard, representatives of leading American machine-tool manufacturers; to Sir Alfred Herbert and Mr. Oscar Harmer, of Coventry ; to Mr. Schofield, Principal of Loughborough Technical College ; Mr. J. L. Hall, of Coventry ; and Mr. Binns, formerly district secretary of the Amalgamated Society of Engineers in the Manchester district.

These men were quick to see the possibilities of the movement and ready to assist it. Conferences were arranged between education authorities, principals of technical schools, and the gentlemen named above, and a clear understanding arrived at as to methods and objects.

Progress subsequent to that conference was continuous and vital. Needless to say, many obstacles were encountered. Trade Union prejudices, or perhaps it would be fairer to say rank-and-file fears due to a variety of causes, undoubtedly retarded progress. Bad works management in the hands of men to whom the production idea was totally unfamiliar constituted another serious difficulty. Such officials merely saw in it a convenient method for tinkering with wages and were blind to the possibilities. It was impossible to convince them that unless they could furnish the Training Department with a detailed analysis of the methods by which they proposed to attack any particular production problem, the whole idea of intensive training at once broke down. It is almost no exaggeration to say that the higher the standard of production attained by a firm, the more intelligent the use made by them of the trained men and women who were sent to them.

But, in the main, the general idea gained acceptance, and progress was continuous. The men and women trained were of all types, varying from country girls with a good Scotch education from Aberdeenshire, anxious to help the national cause, to textile engineers in Lancashire, whose general education, thanks to the cursed half-time system, certainly left something to be desired, anxious to take their chance of being up-graded to more ambitious forms of machine-shop work. In all, at least 50,000 must have graduated through the training establishments into one form or other of war production. Generous testimony was borne by many firms as to the help they had received Most gratifying of all may be quoted a letter from the Department of Aeronautical Supplies, which states :—

"I should like to take this opportunity of thanking you and your Department for the exceptional services rendered in connection with the training and supply of labour. We are certain that if it had not been for this effort, the supply of aeroplanes and aero engines would have been very seriously retarded, if not altogether held up."

When the Armistice was proclaimed, the Ministry had equipped one hundred technical schools with first-class plant, and possessed nearly a dozen large instructional factories, each capable of holding from 400 to 800 learners.

But meanwhile a second problem, and one, in

many respects, of greater difficulty, had been developing. The disabled soldier, steadily growing in number, was asserting a claim to employment. Training in some form or another was clearly necessary for him, but training of a widely different character and with different objects from munition training. It was clearly useless to attempt to train the soldier for work of a temporary nature. What he desired was permanent employment, and for him work under dilution conditions was, from the individual standpoint, really a snare, however highly paid, or however desirable in the national interest. It was necessary, if possible, to devise a system under which he might become a skilled craftsman and be admitted to the ranks of skilled men. This obviously involved negotiations with both employers' organisations and trade unions, and under the general direction of the late Mr. St. George Heath, at one time Warden of Toynbee Hall, and of Mr. D. T. John, of the Ministry of Labour, a series of negotiations were conducted during 1916 and 1917 with well-nigh all the leading British industries. The results of these negotiations were embodied in a series of agreements, to which representatives of employers' organisations, trade unions, and the State were contracting parties. Under these agreements the interests of all were, as far as possible, duly safeguarded—the rates of pay the disabled man was to receive, the amount of State contribution, and the regulation of the number of men to be admitted to any industry—all these considerations were provided for.

Further, at an enormous expenditure of time and labour, these special representative training committees, *i.e.* the National Trade Advisory Committees, composed of employers and workmen, were charged with the duty, not only of devising schemes of training, but of supervising them after they had been devised. These schemes, in their complete state, all have one common feature, viz., a preliminary period varying in length from six to eighteen months to be spent in some technical school or instructional factory, and a further period of eighteen months as an improver in works, at the end of which time the training would be completed and the man would be eligible to become a member of the appropriate trade union. There were also established Local Technical Advisory Committees, constituted on a basis similar to that of the National Committees, whose functions were to select the men for training and to supervise their progress during the period of training. By this means the co-operation and advice of those actually concerned with a particular industry, both nationally and locally, were obtained.

It will readily be recognised that a fundamental feature of the training of disabled men is that careful selection be made, so that a man may be trained for a trade suitable to physical and temperamental disabilities. For this purpose the need for expert technical advice is apparent.

In 1919 the Government decided to take up this question of training on a large scale; in fact, it figured as a definite plank in the platform during the 1918 election. All industrial training was taken over by the Ministry of Labour, in which it formed a separate Department. The *personnel* of the old Training Department was largely represented in the *personnel* of the new Department.

Women, in addition to disabled soldiers, came into many of the schemes. Many thousands of women who had given the apprenticeship period of their lives to the making of munitions, instead of learning some typical woman's trade, found themselves out of employment. It was difficult for them to get absorbed in any of the typical women's industries, as the employer, if staff had to be taken on, naturally preferred the young girl, who was more adaptable and who would not expect the wages of an adult woman. For this type of woman intensive schemes of training had to be devised, which after a brief period would render their admission into typical women's occupations, at reasonable wages, an economic possibility.

It has been calculated that the number of disabled men who will require training facilities is not far short of 80,000. At first it was hoped that it would be possible to arrange for the vast majority of the number by directly placing them in work at the same time making provision for part of their maintenance during the "improver period"; but as the majority of the National Trade Advisory Committees proceeded with this work they became more and more impressed with the necessity of a moderately long period of preliminary training in something corresponding to an instructional factory, winding up with eighteen months as an "improver" in works under careful supervision.

From a Treasury viewpoint, and it may be added from the standpoint of many of the disabled soldiers, this is an unfortunate development. Why, the Training Department is often asked, is the disabled man not sent straight

into works?—on the analogy of the ordinary apprentice—and he can be trusted to absorb the craft by degrees. Unfortunately, the disabled soldier is not a boy but a man, who is endeavouring to do in three years what takes a boy five or six. Experience has convinced all practical men that it is vain to hope for the success of the soldier in an average shop, unless he goes in equipped with sufficient knowledge to enable him to take an intelligent part in actual production.

In the case of very large firms, no doubt instructional bays could be established and treated on the lines of instructional factories; but that would not affect the principle that instruction and production will not blend, but must be kept separated from one another. Under the instructional factory system that divorce from factory life is avoided which, from the point of view of adult training, may be considered the defect of the technical school, and the concentration on production, which from the same standpoint is the defect of the factory.

In the instructional factory the primary object is not the production of components or finished goods, but of skilled men, and it is the chief duty of the manager and of his instructors, who are the equivalent of the charge hands or foremen in the factory, to train men for particular branches of industry by methods of approved utility. The work in an instructional factory takes a practical form from the start; the "preliminary exercises" of a technical school being replaced by simple forms of production work, chosen from the point of view of their value for training purposes, from which the learner passes forward in due course to the more advanced processes. In this way an impression of reality is created and interest aroused. This form of training also provides opportunities, informal or otherwise, for imparting a knowledge of the fundamental principles underlying the various skilled operations, such as can rarely, if ever, be given in the ordinary workshop. Moreover, the instructional factory, working to normal factory hours and with normal factory discipline, affords an invaluable introduction to workshop life, and the worker when transferred to a firm at the conclusion of the training course finds himself in an environment with which he is already very largely familiar.

Briefly, it is claimed for the instructional factory system that by its means a high degree of proficiency can be acquired more rapidly and effectively than through any other system of training, whether in technical school or workshop, than has as yet been tried.

It is no exaggeration to say that this attitude adopted marks a revolution in the several industries as regards the opinion formed of the possibilities of training for actual work in places outside the works themselves. The engineering trade led the way, the reason for this being that they had had a better opportunity than most of the other industries of studying the possibilities of the system during the five years of war.

The National Trade Advisory Committee for the Engineering Industry, which prepared the training scheme, was as representative of the industry both on the side of the employers and workpeople as any body of men could possibly be. They made an exhaustive examination of the various instructional centres; I quote the Chairman's report on one of the centres of which a particularly exhaustive inspection was made:—

"I was very much impressed with my visit. I think it is ideal and you have got the right man in the right place looking after it. If all technical colleges were like that, we should be at the top of the tree. If you could only get other technical colleges formed with equally good men to look after them, you have solved a most important question and rendered a national service to England.

"There are only two points that I consider require most careful consideration and must be faced. The first one is: a certain sum must be put by every year for depreciation, so that the machinery in these technical colleges may be kept up to date. It is not sufficient to put up-to-date machinery in, but the machinery must remain up to date. The second condition, which is equally vital to my mind, is that the work done by the students, or whatever you like to call them, who are working in the college, must be commercial and done at a fixed price, so that students and foremen may realise that the work that is done must be done not only well, but cheaply."

The writer of this paper is far from saying that the question of training disabled soldiers is anywhere near solution, but if premises can be acquired with sufficient speed he is distinctly of opinion that a great part of the problem is capable of solution. But the main point on which for the moment he desires to lay stress is, that all the great industries of England have been forced to conduct an exhaustive analysis of their own methods, and have been themselves primarily instrumental in laying down (and are responsible for supervising) the methods by which in the shortest time a skilled man can be evolved. It might perhaps be advisable to

examine here in detail the conditions which determine the type of training given in the trade which will probably be of most importance in the future—the engineering trade.

It should be recognised as a fundamental fact that the type and amount of skill required in any industry, in any period, exactly corresponds to the degree of accuracy of the measuring tools of that period. In the engineering trade, for example, thirty or forty years ago it was the practice to measure articles with a tool called the caliper, which is really two pieces of steel fastened together and swivelling on a pin. Here the accuracy in measuring was dependent on the skill of manipulation of the calipers, and to gauge the size of a shaft required a great deal of skill on the part of the man. He had to develop what is known as a correct "feel." His accuracy was limited generally to just under the thickness of a paper, although the old time mechanic, where the measurement was a relative one, could gauge its size to an extraordinary degree of accuracy; but, whilst he could tell by "feel" with the calipers the difference between, say, two shafts, he would be unable to register on paper the exact difference between them. The secret lay essentially in the lightness of touch of the mechanic. To-day the modern schoolboy can measure with a far greater degree of accuracy with instruments that not only neutralise the difference of "feel" between two individuals, but also register on a dial the correct amount of difference between various articles measured.

It should be obvious from this example alone that the methods of technical education required to-day differ enormously from those required, say, thirty years ago. Again, the old type of mechanic was frequently asked to repair an engine, and because of the fact that measuring instruments were not sufficiently developed to allow two people to make their work interchangeable, he was accustomed to complete the job himself—turning, shaping and fitting operations would all be done by the same man. You had in those days what I might term a formula—

Simple Machine – Skilled Labour.

To-day, through the development of measuring instruments and machines, and of semi-automatic and automatic machines, hundreds of parts are turned out by different men, every part of which is interchangeable. It will thus be seen that, generally speaking, the old-time mechanic is no longer an industrial requirement, except for highly intricate forms of tool-room work. Technical education to-day requires the production of a useful unit of industry. To be modern, one must train to suit modern requirements and successful technical training requires close co-operation with the modern factory.

A brief statement of the procedure adopted in one of our engineering factories, both during the war and at the present time, should explain exactly the principles involved.

At Twickenham we have an instructional factory devoted entirely to engineering. This factory is equipped with the most modern machinery obtainable. Perhaps the point on which most stress should be laid is that not only is the factory equipped with the most modern appliances used in engineering, but the whole of the atmosphere of the institution is that of the workshop. The chief aim has been to eliminate, if possible, what is known as the "school" atmosphere, and develop factory conditions, so that after the person in training has finished his course he is not only trained in the technique of the industry, but he is familiar with, and able to fall readily into, the usual customs of the trade. His instructors are known as charge hands. He has foreman, works manager and superintendent. He makes out time sheets, and "clocks in" and "clocks out"; so that, when he enters the modern factory he enters as one who is thoroughly familiar with his surroundings and its procedure.

During the war this factory was utilised for the purpose of training women on munition work. The main work of the factory was the production of aeroplane engines, particularly the "Le Rhone" type. The problem facing us at that time was an insistent demand from the factories for a large and speedy supply of people able to do only one or two operations on this type of engine. In the factory one particular operation of the engine would be done by one operator, day in and day out, and the demand from the factory was not so much for a person able to manipulate a particular machine as for a person able to perform a particular operation. This demand was supplied, I think most successfully, by the adoption of exactly the same system in producing the engine as was carried on in the factory requiring the trained persons.

Take a concrete example. What was known as the T piece for the "Le Rhone" engine was done on a Herbert No. 4 capstan. The firm required women capable of doing this T piece. Twickenham factory had a large battery of Herbert No. 4 capstans, and promptly placed the girls in the factory to do these T pieces. They would be given instruction in the art of measuring with

calipers and also with the micrometer. The girl would also be given some elementary notion of tool-grinding, but her main work would consist of turning T pieces. When she left the training factory she left as a competent capstan operator, able to manufacture T pieces and jobs of a like nature.

When it is realised that we had to produce in the short space of three months operators of this type, I think it will be agreed that it was absolutely necessary to specialise up to the hilt. Our problem was to take a girl who had been accustomed probably to nothing but housework, unaccustomed to factory life, and who generally estimated an inch as being equal to the length from the tip of her thumb to the first joint, and make her thoroughly acquainted with the most modern methods of measurement, and also to break the disciplinary conditions of factory life as gently as possible to her. This could only be done in such a short time by the adoption of a National Training School whose conditions were exactly similar to those of the ordinary factory.

To-day, however, the problem is somewhat different. We are asked to train men and make them skilled mechanics. Disabled soldiers, who for some reason are unable to follow their own particular employment, are to be made efficient in a number of trades, amongst them being engineering, and whilst, as already stated, the problem is somewhat different from that of training women for munition work, it is a difference of time rather than technique; for, as already indicated, the type of mechanic required to-day is vastly different from the mechanic of forty years ago. Mass production is the order of the day, and its success depends essentially on the specialisation of labour.

Modern requirements in engineering demand a specialised fitter or turner as the case may be, whose greatest qualification is speed rather than quality. We have now the formula—

Simple Labour – Skilled Machine,

and our chief aim at Twickenham at the present moment is to produce not a mechanic with little bits of theory sticking out all over him and with a slight knowledge of everything connected with the industry, but an efficient workman in a particular trade.

A man who is to be trained in turning, for example, is given a few lessons in measuring instruments, machine drawing, and elementary mathematics. He is then placed upon simple operations involving turning articles to size, and he learns as he works. That is to say, he is placed upon a machine, say a lathe, and given a job to do. He is not only told what it is for and how to do it, but he is expected to do it under conditions exactly similar to those he would be called upon to work under in modern factory life. He is given everything that he will require to become a practical man and an economic unit in his trade.

We have reached the stage, I hope, when it is recognised as being a waste of valuable time to teach a man who is destined to work in tools the elements of civil engineering.

A point worthy of notice is the fact that from the moment our trainee is placed in the factory to the time when, equipped with a full set of tools and a good knowledge of his trade, he leaves the factory, he has never once been asked to do a useless exercise. All the work that he has performed has been of a useful character, and calculated to develop his interest in the work in hand. It is the complaint of many engineers of to-day that the major portion of the time spent by them in technical schools was devoted to exercises involving the fashioning of metal into all sorts of obviously useless shapes. Nothing is more calculated to destroy a person's interest in his labours than the knowledge that the material on which he is working will find its home in the scrap heap. Useless work of an exercise nature, then, is excluded, and the essence of our training is the equipment of men in the shortest possible time with sufficient knowledge and skill to enable them to take their places side by side with the craftsmen of to-day, and earn by their own exertions the recognised rates laid down by the trade unions; and the key-note of success in this direction is the adoption of training schools with plant and methods of production equal to those of the most modern factory.

The reason for the slow progress in production methods in England prior to 1914, was due to the fact that this critical analysis had never been carried out before by industry as a whole.

It would appear likely that this training work, so far as the discharged soldier is concerned, will go forward vigorously for some three years. The Advisory Committees, both national and local, will be functioning vigorously during that period, and instructional factories capable of holding some 20,000 men at one time will be in operation within a comparatively short time.

It is well at this stage to observe that although the general training work is centred in the Ministry of Labour, a great deal of the administrative work is carried on by local education

authorities, and that in many of the most important areas into which the country has been divided, the Ministry have been fortunate enough to secure local directors of education as their administrative officers.

Whatever demand the future may hold for adult training, it is quite certain that the problem of training the youth of the country between fourteen and twenty has not yet been faced.

The Fisher Act may be taken as the first acknowledgment that such a problem exists, but the attempts to put a part of it into operation are not much more than tentative.

That Act provides ultimately for the extension of part-time education of juveniles and adolescents to as high an age as eighteen. In my opinion many of the large population which will be required or entitled to receive such education will not be content with any form of instruction which is not largely vocational, and the instruction must be on lines which will appeal to the working-classes, both parents and the actual recipients, as of direct practical bearing upon their occupation.

There are two other possible directions in which the new system of vocational training may be of value. One is in the re-education of the cripples of industry, the other is the training of men and women thrown out of employment through the fluctuations of industry in the trade on which they have first embarked, for other callings.

As to the first point, it is interesting to note that the French are already considering the diversion of some of the training centres established for the training of disabled soldiers to the training of men injured in industry. If, for example, a soldier, who was formerly a mechanic and through injury to his legs is unable to continue to pursue his trade, can be trained in precious-stone cutting and thus become a contented and productive citizen instead of a discontented burden upon his family, his industry, or the community, there is no reason why the same process should not be applied to the rehabilitation of civilians rendered incapable by industrial injury of following their previous trade. No doubt the great shortage of man-power from which France was already suffering before the war has made this problem to her a more real and pressing one than it is as yet in this country, but in England, too, the present serious shortage of skilled labour, which has largely been caused by the ravages of war, may make it necessary to tackle the problem of the cripple in industry in the near future, even apart from the increasing effect of what may be called humanitarian considerations and the increasing recognition of the duty of the State to those who are incapacitated in its service.

As to the second point, the Ministry of Labour have found in several instances—for example, the clothing trade in Yorkshire—that skilled men and expensive buildings and machinery were standing idle simply and solely because there was a shortage of semi-skilled women to carry out certain parts of the work, for want of which the skilled men were idle and the plant could not be employed. We have found it possible, by training women to perform less skilled parts of the work, to fill the gap and to bring the skilled men and the machinery into operation. I need not enter here into the reasons for which it was found practically impossible for the employers, without State intervention, to fill the gap themselves.

The Insurance Act of 1911 contained an interesting forecast of this possibility, for it contained a clause which enabled the Board of Trade to arrange for the training of unemployed persons where they were satisfied that such training would enable them to obtain employment. So far as I know, neither the Board of Trade nor the Employment Department of the Ministry of Labour, who took over their responsibliity under the Insurance Act, were able to put this clause into operation. It was only under the strong compulsion created by the Armistice, when large numbers of women were thrown out of work through taking on munition work at an age when they would ordinarily have entered some peace time avocation, but were deprived of their normal opportunity of learning a trade while they were still young, that the State was driven to tackle this problem.

The welfare work done in the Ministry of Munitions may be said to have killed stone dead the theory that to throw a lad into a large works and leave him to pick up what he could was any other than a villainously wasteful method of evolving a skilled man, to say nothing of a good citizen.

What was in existence in 1914 was really reminiscent of the old apprenticeship system, under which the boy lived with his master and worked on the very varied jobs as they came in. It was an excellent system, there was a personal tie between the two, the boy received an excellent discipline and a good all-round craft training. It was suited to an age of small private production. It still survives under

satisfactory conditions in the case of the village blacksmith, wheelwright, or small builder.

But this patriarchal condition of things, while it may still function in a country village, is in the main unsuited to an era of huge works and mass production. Personal relations between the employer and the apprentice ceased to exist, and no substitute was provided for them. The whole conditions of teaching the trade altered; but it ceased to be the particular interest either of the employer or the workman to teach the unfortunate apprentice.

The question of what a skilled man should learn, nay more, what constituted a skilled man, was never faced. Even the best employers were satisfied with the old methods of the workshop, and at most thought it sufficient to supplement them by technical and general educational classes. These were good in themselves, but they left the problem of the sequence of training inside the workshop entirely untouched. With English production in the chaotic condition I have described, the problems of 1914–18 had to be faced.

I have described how the Ministry of Munitions attempted to face them. I do not say that their methods were perfection. So far as training was concerned I now believe we might have done better had we done more in the direction of scientifically upgrading in the industry itself. We might have done more in the way of introducing the textile engineer, who had already served an apprenticeship in his own branch of the industry, to the higher walks of engineering, and had we done so we should have encountered less opposition and prejudice than we did. But it seems to me that we established one fact beyond the possibility of doubt, and that was that the waste of time and life in the existing system of craft apprenticeship was beyond computation.

And though our further task of creating a skilled man by the application of intensive methods has not yet reached a stage at which it is possible to talk dogmatically as to possible results, the schemes themselves, which, be it remembered, are the creations of representatives of the industries themselves and not of any bureaucratic Department of State, would seem to warrant somewhat similar conclusions.

The particular point on which I desire to lay stress (and this is the reason why I have written this paper) is to point out that, say, in 1924 at the very latest—by which time we hope that our debt to the disabled soldier will have been discharged, so far as it is possible to discharge it, by means of training—there will be in existence a complete machinery of instruction in every skilled industry in England, and that the joint managers of these industries will be the industries themselves and the State. There will also be by that time, I would hope, chairs of industrial production method in all the new universities and higher technical colleges, while the extension of the school age and the developments produced by the Fisher Act generally, will have raised the whole standard of the entrants to industrial life. In addition, increased wages and a higher standard of living will have rendered the elimination of waste from industry a matter of sheer economic necessity; it will simply not be able to afford the old chaos.

What I plead for is the necessity of watching with the utmost carefulness the results obtained from the present unparalleled experiment. It also appears to me that this experiment has a direct bearing on certain aspects of the unemployment problem. The problem of training the unskilled, and of transference from one industry to another, is clearly not of the hopeless character we were taught to think it.

We are not saying too much if we assert that if we can only reconcile the legitimate interests of particular trade unions with the interest of the common good, we can see daylight through many dark problems. Before that can be done a satisfactory solution to this problem of unemployment must be devised. We must therefore confine ourselves at present to the assertion that the possibilities of transference from one occupation to another are far greater than, before these experiments were commenced, anyone thought them to be. But, as I have always said to my friends at the Board of Education who shrink from the prospect of hearing temples of learning echoing with the din of industrial disputes, the real interest of education lies in the fact that from time immemorial it has been the subject on which the whole world draws knife; nor do I believe that either Mr. Smillie or Mr. Brownlie, Mr. Clynes or Mr. Thomas, can be found more troublesome than the tribe of warring theologians who in the mid-Victorian days were the lions in the path of progress. Considering that the interests primarily involved will be those of their own children, I confidently rely on the intelligent support of Labour in this problem of Training for Industry.

DISCUSSION.

Mr. W. R. Davies, C.B. (Board of Education), said he desired to speak entirely for himself and not for the Department with which he was connected. He was sure everyone present had been very much interested in the author's enthusiastic presentation of the subject, and personally he did not wish to say a word against the claims that the author made as to the success of the schemes for training munition workers, apprentices, and disabled soldiers. He thought, however, that what the author wanted all those present, and himself in particular, to think about was the lesson that the work in question had for those whose lot it was to deal with the industries of the country and the training of the people engaged in those industries, and personally he wished to have the widest opportunities of seeing the work as it progressed. He had spent a certain amount of time in an institution dealing, not with the training of the rank and file, but with a somewhat different subject, the training of the leaders in industry—the production of engineers. He thought the author had been speaking about the rank and file, machine operators, and so on, and he agreed that it would be foolish not to make the very best use possible of the experiments the author dealt with—for they were experiments in their bearing on some of the problems of the future, although they had been very successful for their particular purpose. We ought to consider how what had been achieved could be incorporated into our national life, our national system of industry, and our national system of education. But when one came to practical propositions there were one or two points that it happened to be his business to think about and that he would like to bring before the meeting. At the present time the State was about to spend something like £40,000,000 a year on education, and a great deal more was spent by the ratepayers. Of that £40,000,000 not much more than £250,000 went directly to anything that could be described as technical education, apart from what was done in the universities. The author had stated that about £20,000,000, possibly more, would be spent in the next few years on the instructional factory training of disabled soldiers and apprentices.

Mr. Currie pointed out that that sum included maintenance allowances.

Mr. Davies, continuing, said he believed the training was full-time training, and up to the present nobody had ever suggested that the educational system of the country should include a universal system of full-time training of a technical character for young people who at some later time were going to enter the various industries of the country. That sort of training was only provided to a very limited extent. There were no maintenance allowances, either for those in secondary schools or for those in technical schools, except so far as individual local education authorities, representing the ratepayers, might think it desirable to provide those allowances for promising young people. The expenditure of the London Trade School for Girls was about £20 or £25 a head per year—possibly a little more at the present time, owing to the increased salaries paid to the teachers. He had seen an instructional factory and had heard something about the cost of the machinery it contained, and had heard references to depreciation and obsolescence. Speaking frankly, if the suggestion was that boys should only enter the engineering industry *viâ* the instructional factory, or that a very large proportion of the boys entering the industry should do so in that way, he considered the instructional factory ought to be an instructional bay of the works, run by the firm concerned and not maintained by the taxpayers and ratepayers of the country. If employers, engineering employers in particular, were satisfied with the results of the scheme of industrial training which came into existence during the war—and he had every reason to believe they were—they might think it worth while as a business proposition to undertake similar work themselves if their firm was large enough to do so.

Mr. W. A. Brockington (Director, Leicestershire Education Committee) said he was very glad that the author looked beyond our present difficulties and discontents to the future bearing of his system of training upon our education policy in general. At present one was oppressed with the difficulty of its application to the trainee, the initial difficulty of allocating the right number of trainees to any particular industry, and the even greater difficulty of getting those trainees placed after their institutional training and during what was known as their improver period, and he was glad that the author had looked beyond those difficulties to the future. He was inclined to agree that, whatever might be said of the demand for non-vocational education in our continuation schools, for example, when that education was extended right up to the age of eighteen—as it would be after seven years—there would be a very considerable demand that it should have some relation to the real interests and daily occupations of the students. To that extent such education must be vocational. He did not think that, when what had been done in industrial training was applied to our general education policy, it would have so much relation to day continuation schools as it might have to the higher whole-time type of education. There was room in this country for one or two institutions which combined the teaching on

the mathematical and physical side of engineering with very definite workshop practice, and he hoped what had been done in the past would be applied to the future of education in that direction. There were one or two points that very clearly emerged from all that had hitherto taken place. They were not new ideas; they were old ideas that had been very strongly developed in the minds of many of those who were concerned with education. One of those points was the idea of training upon production, an idea which permeated the elementary schools of this country, where classes were held in cookery, dressmaking, woodworking and metalworking. That added a very great interest to the life of the child. If carried forward to anything like an advanced engineering training that idea would prove very expensive, but was the expense commensurate with the object in view? He thought it was, and that it was a very good thing to experiment along the lines towards which one was directed by that single idea of training upon production—half-time workshop practice side by side with class-room training on the physical and mathematical side of a great industry like engineering. He therefore hoped that the difficulties with regard to expense caused by depreciation of machinery and other matters would be overcome. Another point that had emerged very clearly was the idea of localisation. Those concerned with technical schools had from the very beginning tried to get them into actual touch with the industrial atmosphere of their own neighbourhood. Owing to lack of funds and other reasons that attempt had not been successful in the past, and technical training had to a very great extent lagged behind the actual requirements of the neighbourhood. The technical school, therefore, had not always been looked upon with respect by the manufacturers in the surrounding districts. The idea of localisation, however, was very strongly held, and he believed that the foundation of the local technical advisory committees —which, after all, were only the old technical advisory committees that most really advanced education authorities set up to help them in the various industries—would be a very great help in the future to the cause of education, because they would bring together experts in every particular branch of industry who might be counted upon to explore the needs of the industry and to educate the education authorities.

Mr. H. Purdy said he had spent most of his life in the United States, but he returned to England in 1900 to represent a leading American firm and see if there was any prospect of doing business in this country. He went through many works in Birmingham, Manchester, Newcastle and other places, and he had been astonished at the high efficiency of the labour and the low efficiency of the plants. In many cases the firms did not know the definition of production. One component part had no relation to another from the point of view of standardisation. A sporting gun made by any big firm in England might be a beautiful gun in itself, but owing to lack of interchangeability it might be difficult to get a spare part for it if one wished to do so. At the time he visited England in 1900, bicycles were being imported from the States, where labour and material were both more expensive than in this country. A number of British manufacturers studied the American methods, and within a few years they were making a much better and cheaper bicycle than was made in the States. If that could be done with regard to bicycles it could be done in sewing-machines, motor-cars, typewriters and other lines of a like nature. When the British Government wanted rifles during the war, firms spent money on the necessary plant, with the result that the manufacturers in this country made better and cheaper rifles than were made in the States. The brains were here; England did not have to send to America for them. He had been working with the author of the paper for four years, and had the greatest admiration for him. It was astonishing how he had grasped the mechanical possibilities of England. The boys of this country had the best possible brains when they were trained aright, but why pitchfork them into miserable factories that spent thousands of pounds in keeping the daylight and fresh air out? Actual production was more or less monotonous. There were enormous numbers of unskilled men unemployed; the parents of many large families could not apprentice their boys, for when the lads were fifteen years old they had to help to keep the younger children. This type of unskilled men were the men that actually obtained the production, but the means of obtaining it were in the hands of the highly skilled men. Unlike the actual production, the means of obtaining production were exceedingly interesting. In the factory with which he was connected in America, a great percentage of the workmen were Scotsmen and Englishmen, but they were much more efficient than they were when they left home, owing to working under more efficient conditions and in a different environment. It was often said that highly efficient machinery was too expensive, and many firms worked on the lines of buying low efficient and cheap machines, trusting to the high efficiency of the operators to obtain results. He contended that all the technical schools should be supplied and maintained with completely up-to-date machinery. The low efficient machinery was not only a waste of money, but was also wasting the time of the young men and handicapping their whole future.

Lady Parsons said she had very much enjoyed listening to the author's interesting paper. Women highly appreciated all that the author did for them during the war, by helping them to obtain employment in engineering works, and by successfully devising dilution schemes. The sum of £22,000,000 had been mentioned in the paper as the estimated amount to be spent on technical schools, and she would like to ask whether a little of that might be spent in training women, not in domestic science or laundry, or anything of that kind, but in making them efficient units of such an important industry as engineering. She would also like to know whether, if that was done, there would be any prospect of those trained women being allowed to sell their labour, so that women too might participate in the improved conditions of life that men were claiming with so much insistence. The welfare work and improved conditions in factories that had been brought about were due to the entry of women into the factories during the war—if any air, light and sunshine were now admitted, it was owing to the women; but now they were on the scrap-heap, whilst the men were enjoying the improved conditions that the entry of women had obtained for them.

Mr. Currie, in reply to Lady Parsons, said that with regard to the question of women in engineering works, it might be desirable to see them there, but it was hardly his business, as a Civil servant and a member of the staff of the Minister of Labour, to forecast the future. The second question Lady Parsons had asked was a hypothetical one; he thought she might put it again after a year or two had elapsed and the dilution pledges had been honoured.

Mr. G. E. Hart said he had been very much interested in the paper. As one who had taken a good deal of interest in the training of a number of boys, he took it that the first object was to obtain efficient workmen. He could quite appreciate what had been said in regard to the intensive training of wounded soldiers, because he was actively interested in that work. It must be borne in mind that the trade union rules were withdrawn during the early time of the munition training, and that the rules and regulations laid down by the National Committees of the various trades provided an excellent scheme, not only for training disabled men in particular trades, but also for assuring them permanent employment at the end of their training. Many people had said: "Why train a man for three or four years, when we can teach them to do certain things in a year?" The answer was that a man could not learn a skilled trade under such conditions, and even during intensive training a certain period of time had to be allowed. So far as the printing trade was concerned, that period of time had been arranged as between the skilled workmen and the employers. The periods varied in the different departments, and ranged from one year to four years. The disabled soldiers entered the trade with a clear perception that they had to provide for themselves and their families, and it was only fair that they should be given such a training as would enable them to enter the craft just as well equipped as the ordinary apprentice was when he came out of his time; otherwise intensive training would be useless. When boys came into the printing trade at the age of fourteen, their education was such that they were not fit to be employed for a year or two after their admission to the factory, and the consequence was that, for the first two or three years of their apprenticeship, they were merely errand boys, instead of being able to take up their craft and learn it right away. He therefore thought that boys should, for the first two years of their apprenticeship at least, have such an extension of their ordinary elementary education as would fit them for the trade in which they were going to obtain their living, and even before they left school at the age of fourteen there should be some kind of bias towards that trade. So far as the workshop was concerned, he thought that national workshops for particular trades would be very largely a mistake. First of all, a boy should receive a general education which would fit him for the trade he was going to enter, and then his education should be continued in the technical school and in the workshop combined. It was no good putting a boy into a shop where he knew that the work was not on a commercial basis. He should become acquainted with the varying conditions in an actual workshop, and with the varying grades of work which no national workshop could afford to provide. He wished to lay stress on the need for specialised education for the boy in addition and prior to that which he received in the technical school.

On the motion of the Chairman, a hearty vote of thanks was accorded to the author for his interesting and instructive paper, and the meeting terminated.

WATER-SUPPLY IN JERUSALEM.

The question of water-supply has always loomed large in the history of Palestine. The geological formation of the country accounts for the fact that very little water remains on the surface of the ground, the winter rains percolating quickly through the fissures and crevices. No rivers exist in Palestine, except the Jordan, and there is very little rain during seven out of the twelve months of the year. Once a prosperous agricultural region, it is now a barren waste, largely through the Turks having stripped it of its trees.

A book could easily be written to describe the interesting part which water-supply has played in

the history of Palestine. Hezekiah was instrumental in tunnelling a conduit 1,750 ft. long through a limestone hill with a view to effecting local improvements; and Solomon, Pontius Pilate, and Herod were amongst those who attempted to get a supply of pure water into Jerusalem. It remained for the British Army engineers to do the job successfully in a little less than seventy working days.

The supply of water for Jerusalem is obtained from the springs at Arub, 16 miles to the south of the city and beyond Bethlehem. A wonderful piece of work done by the engineers of ancient Rome was the development of these springs in the form of a gallery, and collecting and conducting the water by an aqueduct into a stone reservoir with a capacity of about 5,000,000 gallons. This reservoir was situated at a distance of some 2,000 ft. from the main spring. From the reservoir the water was conducted to the centre of Jerusalem by an aqueduct which stands almost intact to this day.

British engineers have put the spring and reservoir into service again. The water is now elevated by a pump worked by a 66-h.p. gasoline engine into a new reservoir at the top of an adjacent hill, over 500 ft. above the Temple site in Jerusalem.

Practically every house in the town has its own rainwater cistern, but most of them were found to be in a filthy condition—one had not been emptied and cleaned for nineteen years. The owner of a cistern must now obtain a certificate to prove that it has been put into a thoroughly sanitary condition before it can be filled with pure water from the new supply. The organised effort to provide water for the 50,000 inhabitants of Jerusalem has enabled them to have ten times more than formerly. The picturesque water-seller, with his pigskin pack, will soon be a memory of the past, as also will be the figures of the charming native ladies carrying jars on their heads. What is more important is the improvement of the health of the community, and it is to be hoped that there will be no more of those terrible water-borne diseases such as were so common when Turkish rule prevailed.

INDUSTRIAL LABORATORIES IN ITALY.

Appreciating the importance of applying scientific methods in its industrial development, if it is to solve successfully the great problems of reconstruction and to meet competition from other nations whose industries are more highly organised, Italy is devoting special attention to the questions of industrial experiment stations and of technical education. The necessity for such action is made more urgent by the adoption, in many industries, of an eight-hour day. If the working day be shortened to eight hours, increased efficiency in manufacturing methods must be brought about if production is to be maintained.

In this connection the Italian Government, together with the manufacturers, is establishing experiment stations for the principal lines of industry. In addition to studying new processes and making new applications of old methods, these stations will supply the industries with a trained *personnel*.

According to a report by the United States Trade Commissioner at Rome, four stations have been established—two at Milan, for paper and fats respectively, and two at Naples, for leather and ceramics. Another is being established at Reggio Calabria for essential oils and perfumes, and three more are to be established as follows: At Rovigno, for the sugar industry, in connection with the existing school of beet culture; at Milan, for the development of the refrigerating industry; a third, probably at Rome, to study the distillation of gases and their by-products, and, in general, all the processes of combustion. One section of this last-named station will devote itself to the question of the utilisation of national fuels and lignite. Later on consideration will be given to the creation of stations, on the initiative of the manufacturers, for the electro-technical and photo-technical industries and for dyestuffs.

In order that the standard of vocational education might be raised, provision was made at the end of 1918 for the establishment of laboratory schools. At first there will be twenty of these schools, of which two will be at Milan. In addition to a Government subsidy of 25,000 lire each, the laboratory schools will receive appropriations from the local authorities and the obligatory support of the manufacturers. The schools established during the war at Turin, Milan, Genoa, Modena, Florence, Rome, Naples, and Palermo, will be transformed into laboratory schools. Provision will also be made for the ordinary industrial schools, in all of which short courses of study, both practical and theoretical, will be instituted.

CAMPHOR PRODUCTION IN TAIWAN.

According to information obtained by the United States Commercial Attaché at Tokio, as a result of interviews with officials and selling agents of the Government Monopoly Bureau, and from other sources, the reasons for the decline in the production of camphor in Taiwan in recent years may be summed up as follows:—

There is a shortage of labour to gather the crude material, due partly to the higher wages paid by other industries, especially the sugar industry, and partly to the necessity of going farther and farther into districts which have not yet come under Government control, and are therefore unsafe, in order to get good trees. Labourers prefer to work in safe industries, since the wages they receive in those industries are equal to, or even greater than, the wages paid in this comparatively dangerous occupation. Good trees have become scarce because of the wanton and unorganised cutting down in the past. The companies from which the Monopoly Bureau obtains the raw product

naturally desired to procure the largest quantity of camphor at the smallest expenditure of time and labour. This led to a great deal of waste, only such parts of a tree as gave the largest yield being utilised, while the branches, twigs, and roots were simply neglected.

To systematise the method of gathering the camphor and to prevent waste, these camphor companies have recently amalgamated into one large concern. It should be easy for this combination to compete in the labour market with other industries, as it will be a more simple matter for one company than for three or four to negotiate with the Government regarding the price to be received for crude material, this price being based on cost of production plus a fair profit. It is expected that production will get back to the normal by the beginning of April, 1920. From then on the output is expected to be between 5,000,000 and 6,000,000 kin (kin=1·32 lb.) per annum.

The Government is now engaged in investigations to show the exact amount of camphor which may be expected from all the wild trees in the island, but this survey will not be completed for three or four years. According to a rough estimate, however, the "wild" trees will be available for ten to fifteen years, at the rate of a 5,000,000 kin production per year, after which time the cutting down of the trees, which have been planted by the Taiwan Government, will begin. Although a camphor tree does not reach maturity until it is about sixty years old, it will be necessary at first to cut down trees which are only twenty to twenty-five years old. It is expected that the production will increase as soon as operations on the planted trees commence, before which time all the unsafe districts should be under complete Government control.

The production of camphor during the last four fiscal years (April 1st to March 31st) was as follows:—

	Lb.
1915-16	10,389,521
1916-17	11,506,447
1917-18	7,915,890
1918-19	6,137,732

The Monopoly Bureau sends to Europe what is known as "BB" or "improved" camphor, whereas the United States takes "B" or "crude" camphor. The above figures refer to "B" camphor. In the manufacture of "BB" from "B" camphor there is a loss in weight of 12 to 13 per cent.

OBITUARY.

HENNEN JENNINGS, M.Inst.C.E.—Information has just been received of the death of Mr. Hennen Jennings, which took place on March 5th. He was born at Hawesville, Kentucky, in 1854, and educated at the Lawrence Scientific School, Harvard. After practising as a mining engineer in California (1877-87) and in Venezuela (1887-89), he proceeded to South Africa, where he was consulting engineer to Messrs. H. Ekstein and Co., Johannesburg, and to many Transvaal gold-mining companies, subsequently becoming consulting engineer to Messrs. Wernher, Beit and Co., London (1898-1905). He was also consulting engineer to the Convey Placer Mining Company, Montana, and to the United States Bureau of Mines. In 1903-4 he was President of the Institution of Mining and Metallurgy, London, and he was a member of a large number of engineering and scientific societies in this country, the United States and South Africa. He was elected a Fellow of the Royal Society of Arts in 1901.

NOTES ON BOOKS.

MATHEMATICS FOR ENGINEERS. By W. N. Rose. London: Chapman & Hall.

This work belongs to the Directly Useful Technical Series, and is in two volumes, Parts I. and II., published in 1918 and 1920 respectively. The editor, the late Wilfrid J. Lineham, B.Sc., states in the preface that the books of this series are intended to occupy a midway position between those which are designed to be (1) theoretical, (2) practical. It was the desire to admit the proper amount of scientific explanation, while at the same time omitting matter of purely academic interest. In this endeavour a considerable amount of success has been attained.

Part I. may be stated to be a course of elementary mathematics for engineers, with examples and illustrations largely drawn from engineering practice. It is a graded course, comprising algebra, plane trigonometry, mensuration, and graphs. Chapter VII. is concerned with the practical measurement of irregular areas, such as indicator diagrams, and a good account is given of the practical use of modern forms of the Amsler planimeter and of the application of Simpson's Rule and allied methods. There is no account of the power-driven machines which have superseded the planimeter in the measurement of leather hides, etc. These have been in use for many years in Europe and the United States of America, and some description of the types and the principles upon which they depend, which yield a high degree of accuracy, should find a place somewhere in these two volumes. They may be seen in daily operation in London and other manufacturing towns, and the number of hides measured annually runs into hundreds of thousands. The Leather Measurement Act, passed last year, provides for their official recognition for purposes of trade.

Part II. is devoted to the study of the Differential and Integral Calculus, with the addition of chapters on Spherical Trigonometry and Mathematical Probability. The calculus is treated with special reference to its uses in thermodynamics, strength of materials, applied mechanics, applied electricity, and hydraulics. There are numerous illustrations, and the examples appear to be well

chosen. The chapter on Probabilities will be found useful, but we think more examples might be given, as it is so essential to a practical man to be able to determine the best values that can be obtained from a number of discordant experiments. Too little attention has been usually given to this matter by engineers. The subject is, in reality, as important to them as to astronomers. On page 372 of Vol. II. there is confusion as to the meaning to be assigned to the phrase "linear function of x." $f(x)$ is stated to be a linear function of x in contrast with $f(x^2)$. The oversight should be corrected when a new edition is called for.

The work is well printed, and we have found very few printers' errors. Both for study and reference it is well suited to anyone who is engaged in any branch of engineering.

P. A. M.

Early Bulgarian Art. By Professor Dr. Bogdan D. Filow, Director of the National Museum in Sofia. Berne: Paul Haupt.

One cannot but be struck with the enterprise of the committee of scholars and artists in Sofia who, before their country can have had time to settle down after the devastating effects of the last five years, have been able to produce this handsome volume, printed in English, and illustrated with numerous figures in the text and fifty-eight full-page plates.

The subject is treated historically, and is divided into three main sections: the first kingdom of Bulgaria, the second kingdom of Bulgaria, and the Turkish period. Although, through the ancient Greek colonies scattered along the coast, Greek art penetrated into Bulgaria at an early date, there was a still earlier native art derived from the Thracians. Recent excavations in the burial mounds of Southern Bulgaria have brought to light many specimens of this, which are now to be seen in the National Museum of Sofia; a special characteristic of the period is a love of fantastic representation of animals, and generally the work resembles the Scythian objects of art found in the south of Russia.

It is only natural that in a work of this description one's interest should be centred mainly in the illustrations. These are admirably reproduced, and convey an excellent impression of Bulgarian skill, especially in the carving of wood and stone. The carved wooden doors in the church of Christ in Arbanassi, and the church of St. Nicholas in Ochrida, the marble pulpit in the church of St. Sophia in Ochrida, the door in the mosque of Pazvantoglu in Vidin, the iconostasis in the church of St. Spas in Skoplje—to take but a few, picked out almost at random—are all masterpieces of design and execution. Nor can one overlook the exquisite work in silver, such as the bowl of 1644 in the monastery of Batskovo, and the cross made in Tshipwotzi (17th century). The paintings strike one as primitive and crude in comparison with the high level attained by Bulgaria in the "Arts and Crafts."

GENERAL NOTES.

The King's National Roll.—The first edition of the King's National Roll, a book of over three hundred pages containing the names, address and trade descriptions of patriotic employers who have given undertakings for the employment of disabled men under the National Scheme down to the end of 1919, is now in circulation. The book contains nearly ten thousand names, with full particulars of the scheme, and copies are to be placed at the employment exchanges, in free libraries and other public buildings, with trade unions, employers' federations, and the ex-servicemen's organisations, and in the hands of those whose offers to embrace the scheme have been accepted by the local employment committee of their district. All that the employer has to do is to sign an undertaking that his staff shall include a percentage of disabled men, the percentage being agreed with the local employment committee at the nearest employment exchange. In return the employer has his name placed on the King's National Roll, which is kept for the present at the headquarters of the Ministry of Labour, and is given the right to use a distinctive "seal of honour" on his business stationery. More than one local authority has passed resolutions restricting the giving of contracts to firms who have embraced the scheme, and it may be anticipated that a close scrutiny of the pages will very soon be in progress. Since this book went to press the number of patriotic employers registered has grown to over twelve thousand, and the later additions will appear in new editions of the Roll. The total is still growing, but the supply of disabled men is unhappily by no means exhausted. There are thousands yet to leave hospital; all will have to be found livelihood employment.

Copper in South Timor.—Rich copper deposits have been discovered in South Timor, in the district of Tjamplong. According to the British Consul at Batavia the ore is worth 250 to 400 guilders a ton (£25 to £40 at present exchange), and is reported to be the richest ore in the world. Tjamplong is connected by a motor road with Kolpang, the capital of Dutch Timor, which is about thirty miles away, but a road will have to be constructed from Tjamplong to the mines. It is said that no local labour is available, as the inhabitants of Timor are disinclined even to do the necessary work to cultivate their land.

Power Supply in Victoria.—Boring at Morwell, Victoria, Australia, has revealed within an area of one square mile the existence of between 120,000,000 and 150,000,000 tons of brown coal which can be won by the open cut method. This would be sufficient to provide a 100,000 kilowatt power station with fuel for 150 years. The

Victorian Government, according to the *Engineer*, has decided to erect in the first place a station of 50,000-kilowatt capacity to meet the immediate needs of an adequate supply of electric energy for the Melbourne area. The scheme is sufficient for the needs of the area in 1923, and is regarded as the first step of a greater scheme having for its ultimate objective the linking up of all the available sources of power supply, whether steam or hydro-electric, for the benefit of the entire State.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday afternoons, at 4.30 p.m. :—

April 14.—Joseph Thorp, "The Fundamental Basis of Good Printing." Sir Herbert Morgan, K.B.E., will preside.

April 21.—Air-Commodore Edward Maitland, C.M.G., D.S.O., A.F.C., "The Commercial Future of Airships."

April 28.—Brigadier-General Charles H. Sherrill, LL.D., "Ancient Stained Glass." The Right Hon. Lord Desborough, K.C.V.O., will preside.

May 5.—Dr. C. E. Kenneth Mees, "A Photographic Research Laboratory." Sir Henry Trueman Wood, Chairman of the Council, will preside.

May 12.—

May 19.—John Somerville Highfield, M.Inst.C.E., M.I.E.E., "Electrical Osmosis." Alan A. Campbell Swinton, F.R.S., will preside.

Indian Section.

Thursday afternoon, at 4.30 p.m. :—

April 15.—Sir Geo. Cunningham Buchanan, K.C.I.E., M.Inst.C.E., "The Ports of India: their Administration and Development."

Thursday afternoon, at 5 p.m. :—

May 20.—Brigadier-General Lord Montagu of Beaulieu, C.S.I., "Roads and Transport in India."

Monday afternoon, at 4.30 p.m. :—

May 31.—Albert Howard, C.I.E., M.A., A.R.C.S., F.L.S., Imperial Economic Botanist to the Government of India, "The Improvement of Crop Production in India." Sir Robert W. Carlyle, K.C.S.I., C.I.E., will preside.

Date to be hereafter announced :—

Sir Valentine Chirol, "The Enduring Power of Hinduism." (Sir George Birdwood Memorial Lecture.)

Colonial Section.

Tuesday afternoon, at 4.30 p.m. :—

May 4.—Professor William A. Bone, D.Sc., Ph.D., F.R.S., "Lignite."

Indian and Colonial Sections.

(Joint Meeting.)

Friday afternoon, at 4.30 p.m. :—

June 4.—Professor Sir John Cadman, K.C.M.G., D.Sc., F.G.S., M.Inst.C.E., "The Oil Resources of the British Empire."

Dates to be hereafter announced :—

Graily Hewitt, "Rolls of Honour."

Charles Crowther, "The Arts and Crafts of Japan" (with examples from the author's private collection).

William Cramp, D.Sc., M.I.E.E., "Pneumatic Conveying Plants, with special reference to the Transport of Grain."

Cantor Lectures.

Monday evenings, at 8 p.m. :—

Walter Rosenhain, B.A., D.Sc., F.R.S., Superintendent, Department of Metallurgy and Metallurgical Chemistry, National Physical Laboratory, "Aluminium and its Alloys." Three Lectures.

April 12, 19, 26.

Arthur Thomas Bolton, F.R.I.B.A., F.S.A., Curator, Soane Museum, "The Decoration and Architecture of Robert Adam and Sir John Soane, 1758–1837." Three Lectures.

May 3, 10, 17.

MEETINGS FOR THE ENSUING WEEK.

Monday, March 29...Farmers' Club, at the Surveyors' Institution, 12, Great George-street, S.W., 4 p.m. Mr. W. A. Haviland, "Land Tenure."

Geographical Society, 135, New Bond-street, W., 8.30 p.m. Commander D. G. Hogarth, "War and Discovery in Arabia."

British Architects, Royal Institute of, 9, Conduit-street, W., 8 p.m. Mr. D. Joseph, "Higher Buildings for London."

Tuesday, March 30...Illuminating Engineering Society, at the Royal Society of Arts, John-street, Adelphi, W.C., 8 p.m. Mr. J. W. T. Walsh, "Motor-car Headlights in Relation to Traffic Requirements."

Photographic Society, 35, Russell-square, W.C., 7 p.m. Mr. E. W. Harvey-Piper, "Gloucester Cathedral."

Zoological Society, Regent's-park, N.W., 5.30 p.m. 1. Sir Frank Colyer, "Exhibition of Skulls of *Macacus rhesus*." 2. Dr. C. F. Sonntag, "On Abnormalities of the Abdominal Arteries of a Young Panda." 3. Mr. A. Loveridge, "Notes on East African Lizards collected 1915-1919, with Descriptions of a New Genus and Species of Skink, and a New Subspecies of Gecko." 4. Mr. A. M. Altson, "The Life-history and Habits of Two Parasites of the Blowfly."

Wednesday, March 31...Post Office Electrical Engineers, Institution of, at the Royal Society of Arts, John-street, Adelphi, W.C., 5 p.m.

PROCEEDINGS OF THE SOCIETY.

COLONIAL SECTION.

A meeting of the Colonial Section was held on Tuesday, March 2nd, 1920; Colonel Sir Thomas H. Holdich, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., in the chair.

The Chairman, in introducing Mr. Scott Elliot, said the subject of his paper, which dealt with the whole length and breadth of Africa, was a most fascinating one. It was not so much the result of the war as what had taken place since the war that had made it so evident to the British public that it was more necessary now than it had ever been before in the world's history that Britain should develop to the utmost capacity possible the resources of her over-seas Colonies, in order that she might obtain all the raw material supplies which were so necessary for her well-being. In the consideration of such a complicated problem as that under discussion, it was a great advantage to obtain the opinions of men who had actually been in the Colonies and who had brought back a record of what they had themselves observed. One did not want theorists in such a matter, but men of practical experience, and such a man was Mr. Scott Elliot. Some years ago the Royal Geographical Society awarded the Cuthbert Peek Grant to Mr. Scott Elliot for his exploration of the region to the west of the Victoria Nyanza Lake, and in 1906 he read a paper before the Royal Society of Arts on the commercial prospects of British Central and East Africa. Since then he had seen service in the war. Some little time ago it was hoped that Colonel Steele, who was well known to the Royal Geographical Society, and who had contributed some most important papers to the literature on Africa generally, would be able to attend the present meeting. He, however, very much regretted to say that Colonel Steele had since died at Omsk in the discharge of his duties as a British instructor in artillery.

The paper read was—

TRADE ROUTES FOR THE BRITISH EMPIRE IN AFRICA.

By G. F. Scott Elliot, M.A., B.Sc., F.R.G.S.

At the present moment, that is to say within the next five years, there are opportunities in British Africa which I am afraid are not realised by the general public. Just now we either hold or have a sort of option over nearly a third part of the Continent of Africa, but, unless the chances of to-day are developed with energy and on a carefully planned and designed scheme, it will be the privilege of some other nation to spread commerce, civilisation and Christianity through the most backward of all the continents.

My own experience of the countries concerned is antiquated and perhaps out of date. It is twenty-five years since I trudged the whole weary way from Mombasa to the Victoria. At that time it was a matter of two and a half months to reach Uganda; now it is hardly more than two and a half days. There was then neither railway nor road, except in the very first part of the route. Nairobi did not exist. I do not think there were more than twenty Europeans in the whole of East Africa. Now Nairobi has a population of 15,000, a town council with six hundred municipal rules, five hotels, rickshaws, motor-cars, horses, even a pack of hounds, and the railway system amounts to something like 800 miles.

Though I had my full share of the adventures and alarms incident to travel in those early days, I will only mention that the expedition was a botanical one and that I was collecting plants throughout the whole way from Mombasa to Uganda, on to Ruwenzori, and across Ankole thence by the Kagera Valley, through Urund to the head of Tanganyika.

I had thus a good opportunity of estimating the resources of this wonderful asset of the British Empire, and am thankful to say that there is extremely little of what I ventured to publish at the time that I would like now to withdraw.

The experiences of the last twenty-five years have shown conclusively that there are at least five main climatic divisions in tropical Africa which must be carefully distinguished.

Valleys and alluvial flats as well as all the lower ground up to 3,000 feet altitude make up the first zone. Originally occupied by wet jungle such as that of the Zambesi or the Congo or by the east coast tropical forest, land at this altitude can never be healthy for a European. It is a country for sugar plantations, palm-oil, cocoa, and perhaps rubber and a certain amount of other valuable tropical products. The natives are usually the least interesting and most backward of all Africans, and are also of poor physique.

In country such as this no white man can retain for more than a very short time his normal vigour and energy. Not only are there frequent cyclonic disturbances of his system due to malaria, dysentery, and other tropical ailments, but the regular daily climate is exhausting, and depresses even the strongest natural constitution. Frequent visits to Europe are necessary.

The second zone, between 3,000 and 5,000 feet in altitude, which includes a large part of Nyasaland and Uganda, is entirely different. The climate is not of the same exhausting and debilitating character. Europeans can retain a white man's normal energy for five or ten years, and, as has been proved during the last twenty-five years, conditions generally are probably better than in many parts of India. This zone is characterised especially by cotton, coffee, tobacco, maize, and other important products.

Above 5,000 feet there are large districts which are covered with grass or thin forest; the rainfall is not excessive, and one finds occasionally frost at night; on these plateaux and mountain ridges the climate is to all intents that of Europe; a white man can remain European in vigour for an indefinite time, and white women and children can not only live, but thoroughly enjoy their lives. British East Africa, *e.g.*, contains an enormous area of this sort of country. Sir Harry Johnston's estimate is 10,800 square miles for the eastern section alone.*

* See *Geographical Journal*, January, 1902.

It is a difficult question as to whether these temperate highlands will ever be colonies in the Australian or New Zealand sense. I have heard recently that "nerves" make it impossible to stay more than ten years in Nairobi. Of this I cannot speak, for in the nineties one never heard of this disease. The point is an important one and requires careful research. But whether Europeans can live permanently in the Nairobi highlands or not, manual and heavy labour will always be done by the native African. I do not think any well-informed person would have it otherwise, even if it were possible, which it is not.

The importance to tropical Africa of these temperate highlands can hardly be over-estimated. Each of them is a possible centre, an embryo nucleus for commerce, civilisation, and Christianity, from which development will radiate in every direction.

The Empire in Africa contains, and fortunately, not one but at least four of these temperate highlands; we also have a mandate to develop and control two others, which were formerly in German hands.

There are, of course, other districts which cannot be classed along with the three which I have mentioned above. Much of Africa consists of acacia or scrub forest of a very dry or semi-desert character, such as most of Jubaland, Somaliland, etc. The value of such country is, at present, negligible. Then there are mountain forests such as those on Mlanji, Ruwenzori and Kenia, with a very high rainfall. A certain number of tea plantations will no doubt be possible on the slopes of one or of all these glorious mountains, and there are other possibilities as yet rather undefined.

The distribution of these five varied climates is intricate, but the future of trade depends on their differences being thoroughly understood; otherwise great waste will be inevitable.

But one may say generally that the architectural plan according to which Africa has been designed and constructed gives a very simple guide to the location of, at any rate, the temperate highlands or health centres.

Beginning near Beira in the Pungwe River plains, there is a remarkable trough or Rift Valley, generally some thirty to forty miles or more in width, which runs nearly due north to the head of Lake Nyasa. This belt of country has been let down, so to speak, or has sunk during the contraction of the earth's surface; from which it follows that elevated tracts of land, plateaux, ridges, or mountains, parallel

its course; they are sometimes on the eastern, sometimes on the western, and occasionally on both sides of the Rift Valley.

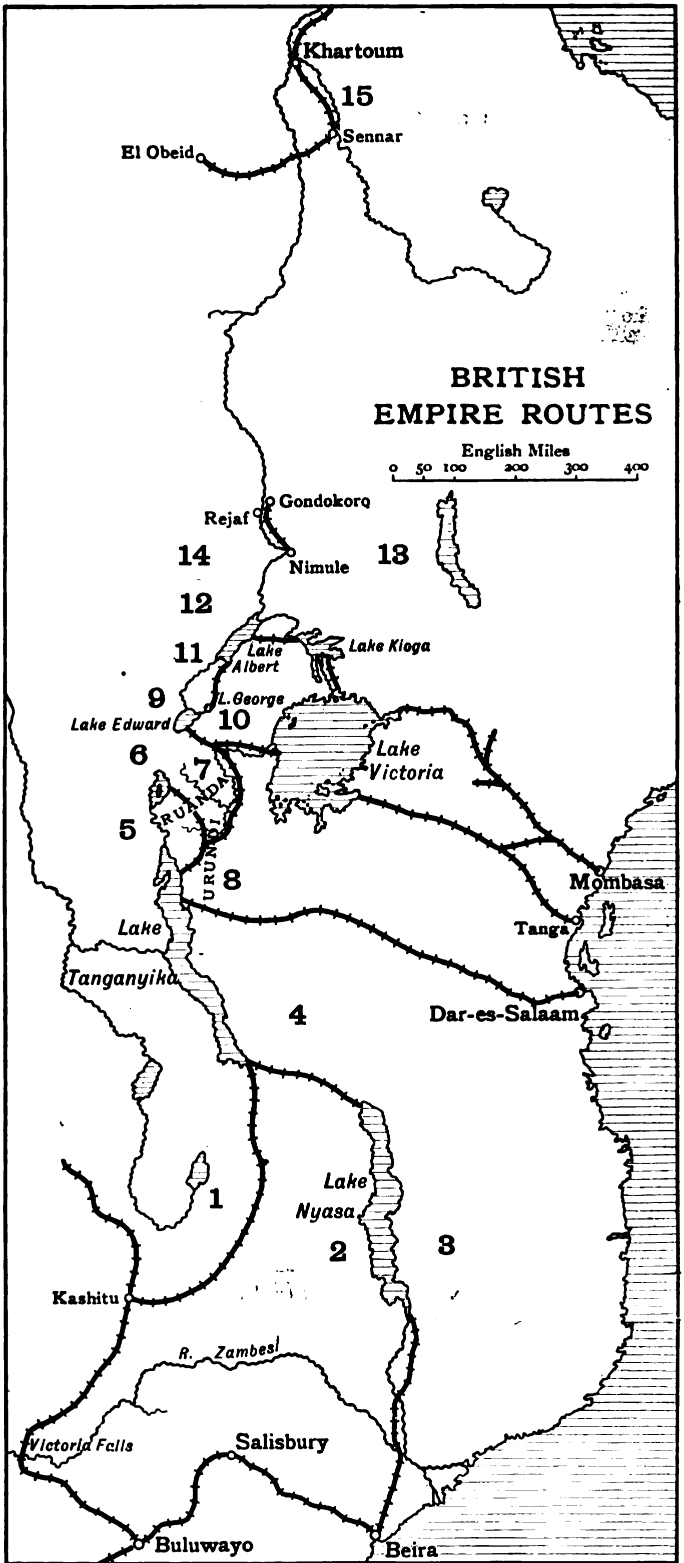
From the head of Lake Nyasa it is continued right up through German East Africa and through British East Africa to Lake Rudolf, and even farther, but I do not want to go into geological details.

A branch Rift Valley, the Central African Rift or Trough, contains the chain of great lakes, Tanganyika, Kivu, Edward and Albert, as well as part of the Nile Valley.

If one remembers this roughly Y-shaped Rift Valley system, the number and positions of the various temperate highlands can be quite easily grasped. They are found to right and left of this gigantic Y-shaped valley or trough.

It is unnecessary to do more than refer to Southern Rhodesia. The eastern edge of the South Rhodesian plateau, which is limited by an abrupt scarp of over 5,000 feet, can be traced for over two hundred miles.

A little further north, if we suppose a rough section taken across the Rift Valley, one finds first the lower ground about Lake Nyasa, which is a most promising cotton, coffee, and tobacco country. It is flanked to the west by the Nyika plateau and the high land about Fort Jameson. After the rather narrow but deep trench of the Luangwa Valley, there is a great healthy highland, the "Plateau" of North-eastern Rhodesia. North-eastern Rhodesia, including Fort Jameson and the Nyika



plateau, form the first (No. 1) of our estates. Here there is probably an area of some 12,000 square miles over 5,000 feet in altitude. Most of it is covered with grass or thin forest. It is extremely healthy and enjoys a European climate, with night frosts in June, July and August. Cattle thrive and are increasing in numbers. Wheat, oats, maize, barley and potatoes do very well. The Awembe, formerly mere land wolves, robbers and raiders, are now becoming usefully industrious.

The "Plateau" is an ideal site for development. Valleys such as the Luangwa, that of the Luapula, and the low ground about Lake Bangweulu are, of course, not included in this highland area. Not only cotton, but rubber, tobacco and coffee have given promising results at these lower altitudes. Sir Frederick Lugard and a very small band of gallant volunteers freed the whole of this region from the tyranny of the Arab slave trader, and the natives are now increasing in number and prosperous.

The lower ground between 3,000 and 5,000 feet about Lake Nyasa forms No. 2 of our undeveloped estates. It is not necessary to give details of its products, for cotton, coffee, tobacco, maize, wheat, ground-nuts and rubber have advanced far beyond the experimental stage.

Hitherto development has been choked and strangled by bad communications. A bale of cotton, *e.g.*, has to be sent by rail from Blantyre to Chindoia; it is then taken by river steamers down the Zambesi at a cost of 82*s*. per ton (Blantyre to Chinde). Here it is again transhipped (for the bar at Chinde has only twelve feet of water at half tide), and goes to Beira (freight 30*s*.). From Beira it is carried to Liverpool at a freight of 115*s*. per ton.

A through railway from Beira to Blantyre and on to Lake Nyasa is an urgent necessity. When the railway has reached (it is to be hoped) Malindi, the whole coast-line of Lake Nyasa (probably 800 miles) will be opened up. A most promising sign is that a large part of the cotton grown now is cultivated by the natives themselves. Probably not one-fifth part of Nyasaland, our estate No. 2, which is 40,000 square miles in extent, has as yet had any chance of developing. Mount Mlanji, with its tea plantations and timber forests differs from the rest of the Protectorate, but has its own possibilities.

On the east of Lake Nyasa, there is in Portuguese and former German territory, a very large area over 5,000 feet in altitude. Some of it, from the descriptions of Stevenson Hamilton and others, certainly consists of healthy grass-covered highlands; this includes the Livingstone range, and other hills forming the watershed.

This estate (No. 3) is quite undeveloped. A large part of it has not even been, so far as I know, prospected. When the railway reaches Lake Nyasa it will begin to go forward. The Trans-Zambesia railway from Beira is already in course of arrangement, and also the necessary continuation to Lake Nyasa.

If this communication to Beira is opened up within the next two or three years, exports and imports should come to Britain. If not, one or other of the competing schemes, either a Portuguese railway to Quilimane or to Mozambique, or the line planned by the former German authorities to connect with the Midland Railway or with the Port of Lindi, will assuredly divert the commerce of these three huge estates to Belgium or Germany.

But you will observe that this Beira railway, though it opens up Lake Nyasa, does not properly serve North-eastern Rhodesia.

Another line is required starting from Kashitu on the Rhodesian system to Kituta and Abercorn. There it should connect with a line from Tanganyika to Lake Nyasa.

The Beira-Nyasa railway is necessary even if it is only to cope with the very promising cotton, coffee, tea, and other possibilities in Nyasaland itself, but it is not by any means enough.

North-eastern Rhodesia, the Stevenson Road plateau, and Kondeland require a direct line of communication with the vast expanding markets of the Transvaal and Rhodesia. I need not spend time on this part of the question, for Mr. H. Wilson-Fox, in the February number of the Royal Geographical Society's *Journal*, shows, on the authority of Lieut.-Colonel Murray, D.S.O., that the construction of a railway from Kashitu north of Broken Hill *viâ* Serenje Mpika to Kasama, Abercorn, and the port of Kitutu on Lake Tanganyika, would be simple and easy. This would be between five and six hundred miles long and place the huge coast-line of Tanganyika within the grasp of British enterprise. Also a connection between Tanganyika and Nyasa, either from Abercorn to Karonga or from Bismarckburg to Mwaya, is clearly an essential matter. This taps the whole of the healthy highlands to the east, and also affords an alternative to the direct route to the port of Beira. I refer you to Mr. Wilson-Fox's paper for details.

Though the Beira line is an essential main line, it is a fact that a large part of it runs

through Portuguese territory, and ends in a foreign port.

Lake Tanganyika is a magnificent waterway, with a coast-line of more than 1,000 miles. Its altitude is variously estimated between 2,740 and 2,759 feet, and it is the second deepest lake in the world, for a sounding of 4,708 feet has been recorded. There are also good harbours. The climate is not at all healthy, but before sleeping sickness ravaged the country, there were large native populations at Karema and three other places along the eastern shore, and coffee, palm-oil, rubber, bananas and other products are grown. To the north at Usumburu begins the rich district of Urundi, which I hope to refer to later.

Along the west side, the country is broken and in places mountainous, but there is on this side continuity with the Congo river system; some suppose that in Jurassic times the sea extended to Lake Tanganyika.

From our point of view, however, the important point is that there are, on the eastern side, two healthy grass-covered plateaux or mountain ridges which can be considered as temperate highlands or health centres. The first (No. 4) lies about 8° latitude, but extends south to our Estate No. 8. I have not been able to get definite information of its extent or altitude, but it is high, well-watered, and grass-covered. It is close to the mission stations of Kirando and Kala, and is also a little north of Bismarckburg.

Further north a similar plateau densely peopled and supporting large herds of cattle is found east and north-east of Kigoma. I do not include this district or the Kitunda mountains, for they are obviously already well served by the direct Kigoma-Dar es Salaam Railway.

As one reaches the northern end of Tanganyika the prospects become more and more promising. On the western side there are grassy highlands 6,000 to 8,000 feet, as well as fine open country at elevations of 5,500 to 9,000 feet to the west of the Rufisi River and Lake Kivu. The grass is short and sweet and the country full of cattle, and apparently well-inhabited. Sir Alfred Sharpe has described this district, and I will call it Sharpe's Highlands.

It is, of course, in Belgian territory, but it should be remembered that it exists when one considers the development of Lake Kivu. We therefore call it No. 5.

On the eastern side of the Rift Valley, before it is interrupted and obliterated by the gigantic transverse ranges of the Mfumbiro volcanoes, are the rich countries of Urundi and Ruanda.

If we take a rough cross-section of the Rift Valley in this latitude, it shows on the west Sir Alfred Sharpe's Highlands, then Lake Kivu itself, lying below 5,000 feet, and on the east again the great green pastures and mountain ridges of Ruanda and Urundi, which rise well over our limit for European settlement.

Lake Kivu itself (No. 6) is said to be the most beautiful lake in Africa. The scenery, following a nice phrase of Grogan's, is a happy blend of Scotland, Japan and the South Sea Islands. There are hills with magnificent pasture and patches of volcanic soil of a very fertile character, but there are also thick tropical forests, barren lava flows and volcanic eruptions are to be expected. Ordinary tropical products should be produced in abundance and without difficulty.

Ruanda (No. 7) and Urundi (No. 8) are admitted by all who have seen them to be perhaps the most promising countries in the whole of Central Africa.

The first has an area of 10,000 square miles and Urundi 11,000 square miles (our northern counties of Northumberland, Cumberland, Westmorland, Lancashire, Durham and the North Riding of Yorkshire amount to about 10,000 square miles).

The population of these two countries is estimated by Dr. Schnee (formerly Governor of German East Africa) as 4,000,000, which is about half the supposed number in the whole enormous area of German East Africa. There are huge herds of cattle. Indeed, all round Lake Kivu Sir Alfred Sharpe estimates 6,000,000 cattle, that is from all these districts, Nos. 5, 6, 7 and 8. The exports from Bukoba were as follows: In 1908, hides and skins weighing 229,000 kg., and valued at 202,000 marks; in 1912, hides and skins weighing 1,119,615 kg., and valued at 1,756,033 marks.

A considerable amount of hides reaches Mombasa from this district even now, so you see that the prospects are extremely promising.

Besides the undoubtedly healthy character of the Ruanda and Urundi highlands, which, as we have observed, are "flowing with milk and honey," the lower ground is extremely fertile. The natives are strong, peaceable, and industrious, and the Wahutu are excellent agriculturists.

I remember even to-day the swarming population and multitudinous banana groves of Urundi near what is now Usumburu. Beans (two or even three crops per annum), peas,

sweet potatoes, earth-nuts, rice and tobacco are grown, as well as millet and other crops.

You will see then, surely, that here there are estates of the greatest value. Such trade as exists finds its way either across the Victoria or to Tanganyika and down the Midland Railway.

Now let us pass along and up the Rift Valley to Lake Edward. The district bordering this lake in British territory (No. 9) is not attractive; but it can hardly be possible that along all the coast-line of a lake of this size there is nothing of value. The salt mines at Katwe have been abandoned to the Congo Free State.

It is otherwise with the grassy and thinly-forested highlands of Ankole (No. 10), which are confidently expected to become the sanatorium of Western Uganda and are surely another health centre for the development of plantations and commerce. With Ankole may be included Rukiga, a wild and rugged land of long, narrow ridges running north-west to south-east, with broad rounded tops and very steep-sided valleys, sometimes narrow and with swift streams, or broad and full of papyrus swamps. The country (after Major Jack) is healthy, and lies at 6,000 to 8,000 feet altitude, and there is no fever.

Passing further north, we arrive at Ruwenzori (No. 11), which is a gigantic upthrust mountain, mostly forest-covered. During my four months' stay in this most interesting of all the countries I have ever seen, it rained almost incessantly. On the lower slopes there are chances for plantations of tea and other tropical products. Ruwenzori resembles Mlanji and Kenia in prospects. It is too soon to say what may or may not be done on these splendid hills, and the discussion of this would be far too elaborate a question to open to-night. At any rate, there will surely be no lack of passengers to the Mountains of the Moon while practical questions are being decided from the results of experiment.

Further north, the Rift Valley is occupied by Lake Albert, which is a beautiful waterway, with a good harbour at Butiaba. A rough section shows on the west, again a splendid health centre, the Balegga Highland, which is a grass-country of a fertile and promising character, and with, close to it, the valuable Kilomoto goldfields and all that can be obtained from the forests and rivers of the Congo (No. 12). A motor road leads from this plateau to the northern end of Lake Albert. The strip of low-lying land on either side of Lake Albert is too narrow to be of much importance.

On the eastern side lies the Protectorate of Uganda, of which the prospects are fairly well known and need not be considered.

But I am tempted to add another estate (No. 13) situated to the east of the Nile, and close to and over the boundary of the Anglo-Egyptian Sudan.

It is the district containing the hills and mountains known as Latuka, Egadang, Dodinga, Kimoto, and perhaps Laroma. Very little is certainly known of these districts, but from the fine descriptions of the late Captain Leeke it seems probable that there are here not only fine forests, but grass plateaux and fertile, well-watered valleys. We will call it Leeke's Mountains. One river falls a sheer thousand feet into the valley of the Kos. The area lies between 32½° to 34° longitude and from 3° 30′ to 4° 30′ N. latitude, but only part of it is high land.

Moreover, on the western side of the Nile, the watershed between its system and that of the Congo is reported as being for a considerable distance fine grassy ridges with a sufficiency of water. This I will call Dr. Christy's Highlands, after the explorer who has specially drawn attention to it (No. 14).

But as regards the actual valley of the Nile (Bahr El Jebel), in what may be called the Sudd region, the prospects are hardly promising so far as trade is concerned.

Sir William Willcocks takes a very hopeful view in his "Egypt Fifty Years Hence": "From Lado to Khartoum will be one unbroken stream about 500 metres in width, of pure and wholesome water, with long rows of willows by the waterside on either bank. The sudd regions and the sudd marshes even, in great part, will have ceased to exist, and in their place will be the beginning of millions of acres of rice-fields and water-nuts."

At present this valley of the Nile north of Lake Albert is unhealthy. Mr. Cana describes the wide unknown region stretching to the border of Abyssinia as "an undulating plain, a swamp in the rains and a thirsty land at other periods of the year. It probably possesses much sylvan richness, and supports a considerable population of unsophisticated negroids."

Nevertheless there are possibilities, for these same people appear to have great herds of cattle, and certainly hitherto they have had no chance to develop.

At the Murchison Falls, which are 140 feet in height, the Nile is contracted to a narrow rock cleft not twenty feet wide; the discharge

is probably constant at about 20,000 cubic feet per second. Surely this is an ideal position for an electric power-station.

There is clear navigation from Lake Albert for 140 miles northward. Then follow some 100 miles of rapids and falls, after which from Gondokoro the fall is only two inches per mile for 1,080 miles northward, and the only obstacle to navigation is the sudd.

In the Ghezira plain (No. 15), between the White and Blue Niles there is the most promising cotton proposition in the world. Some 4,500 square miles (between three and four million acres), are suitable for cotton, and there appear to be good prospects of this enormous area being actually developed provided irrigation can be obtained.

Now, as to the necessary lines of communication for opening up and developing these enormous assets. The Ghezira plain and the whole district of the Bahr El Jebel as far south as Gondokoro is already provided for. The natural outlet is by the Nile and out to Port Sudan, which is said to be a good harbour. But there is a break between Nimule and Rejaf of 100 miles.

British East Africa, the whole coastline of Lake Victoria and of Lake Kioga, are already tapped by the Mombasa-Victoria Railway and its continuation from Jinja on the Victoria to Lake Kioga. This railway must obviously be continued to Butiaba on Lake Albert.

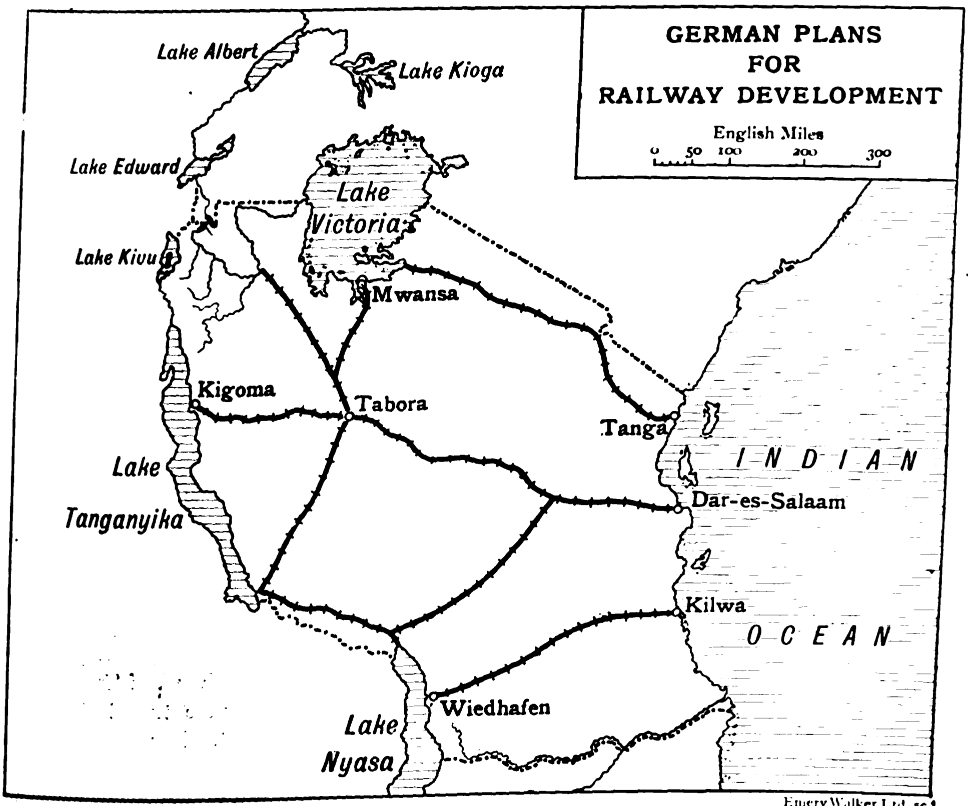
But you will observe that the Murchison Falls, Lake Albert, Lake George, Ruwenzori and Lake Edward, are not provided with any line of communication except roads and tracks.

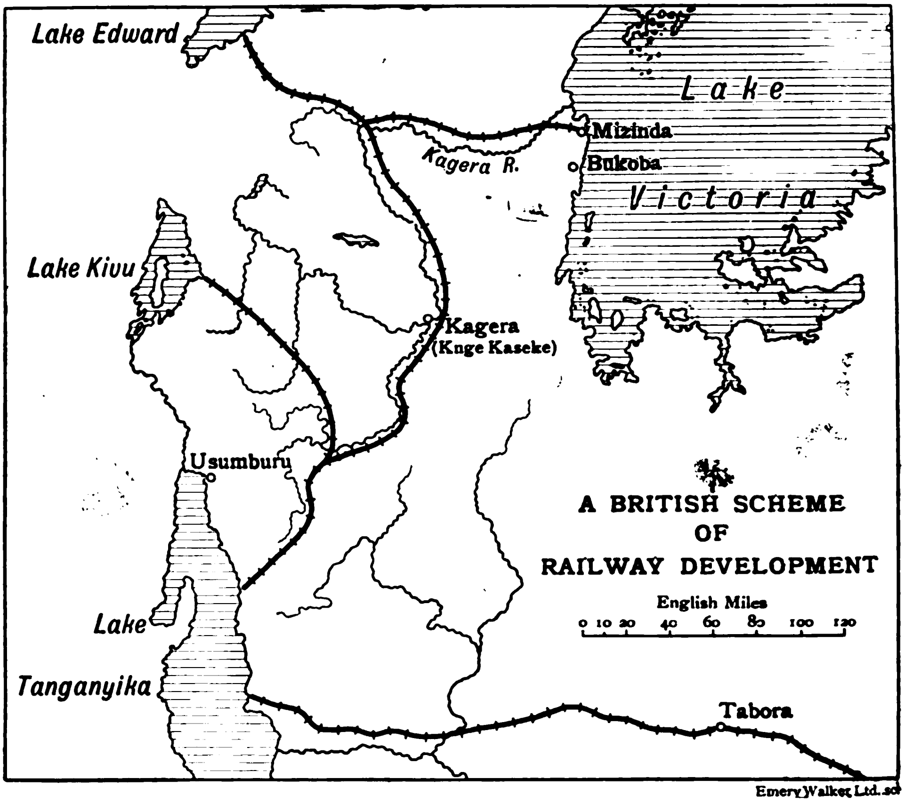
As regards what was formerly German East Africa, the railways actually built and the plans for their extension are well worth close attention.

The Tanga-Kilimanjaro line supplied not only the settlers in the healthy highlands near that mountain, but was most useful in war time.

The Midland to Tanganyika from Dar es Salaam tapped the enormous coast-line of that lake. A branch was to have been built from Tabora to the Kagera Knee near Nyaka-hassa or Kaseke.

This place is a nodal point for future traffic of the very first importance. Starting from Kaseke, which is the Ruvuvu confluence, stern-wheel light-draught steamers could explore the Ruvuvu, which is navigable for twenty-five miles, pass up the Nyaworongo for 200 miles as far as a point within forty miles of Lake Kivu as well as along its tributary the Akenjaru (also navig-





able for sixty-five miles) and along the Kagera itself for 125 miles to the very border of British territory.

Later on, a side line was to go to Muansa on Lake Victoria. From Kilimatinde a branch was to have been built to Lake Nyasa or else a separate railway direct to the sea at Lindi.

Let us consider this system a little closer. All trade from Kivu, Ruanda, and Urundi would be intercepted on its way to the Victoria and carried to Dar es Salaam. So also with any trade from Lake Nyasa, our districts Nos. 3, 4, 5, 6, 7, 8 and 10.

It is true that some, indeed most, of the best German specialists objected to these plans. Thus Dr. Meyer preferred a line from Lake Victoria to the Kagera Knee. Father van der Burght proposed a somewhat different route leading direct to Lake Kivu. Quite a number of German authorities pleaded hard for a railway from Moschi to Aruscha and thence to Lake Victoria.

Commercially those objections were very sound. They were based on a thorough knowledge of the country and its possibilities, but the German Government wished to prevent any traffic reaching the Victoria. Once all the Kivu-Urundi-Ruanda trade had got well into the habit of going to Germany, then they would open the Victoria connection and compete with the Mombasa Railway for the whole trade of that huge inland sea.

As interior lines of communication, and for military purposes, one could hardly wish for a better system.

Had Germany been content to wait in peace and quietness, I have no doubt that nearly one-third of the trade of Africa would have drifted into her hands!

As, however, it is necessary to develop these estates in the interest of Great Britain, the problem is radically different.

For British trade, however friendly our relations may be with other nations, the first necessity surely is that communications should be with British territory and end in a British seaport.

This rules out many of the plans already put forward, *e.g.*, the line already surveyed by the Belgians from the north end of Tanganyika to Lake Kivu and on by the Semliki River to the west of Lake Albert. It also rules out the "Christy" route by the Nile-Congo watershed (see Wilson-Fox). Also, and obviously, the

Tabora-Kagera Knee connection drops out. It was designed by the German Government to destroy British trade with Ruanda and Urundi. It has been most clearly pointed out by Dr. Meyer, Father Van der Burght and others, that this line does not develop Urundi and Ruanda, and is clearly commercially and economically inferior.

What is required is a rail connection between the Victoria and Tanganyika, also between Lake Edward and the Victoria, and such connections should also develop and open up those five vast and promising estates—Sharpe's Highlands, Kivu, Ruanda, Urundi, Lake Edward and Ankole-Rukiga

Now, part of this country has never been, perhaps of design, accurately mapped. One must also and of course admit that a special survey by thoroughly competent railway engineers is necessary before any route can be safely recommended.

Nevertheless, if you consider the wanderings of that vagabond and doubtful-minded river, the Kagera, you will see, I think, that there is a possible route which appears to fulfil all essential requisites.

There is a fair to good possible harbour at Mizinda on Lake Victoria. Thence a railway up the Kagera River would be possible. Colonel Delmé Radcliffe says: "From the mouth of the river to the thirtieth meridian, a road might be traced without any appreciable change of level . . . From the lake shore 3,726 feet above the sea, to Lake Karenge 4,500 feet, the rise is a perfectly gradual one of 775 feet approximately . . . The line could be constructed under the easiest imaginable conditions."*

Moreover, just west of Karenge Lake is the Ruakatenge swamp, practically on the watershed between the Kagera and Lake Edward. If a railway is practicable, therefore, from Lake Karenge along the Kahenji, Chombo or Ntungwe river to the shore of Lake Edward, then half the difficulties disappear. Ankole-Rukiga and Lake Edward, as well as its continuation, Lake George, and Ruwenzori would be in rail or steamer communication with the Victoria and so with Mombasa.

To reach the important nodal point of the Kagera Knee should be a perfectly simple matter; the only difficulty then is to connect this with Tanganyika and Kivu.

Now, German experts state that Father van der Burght knows Urundi and Ruanda better than any other European; the route suggested by him, and no doubt after careful consideration, takes us to Lake Kivu through the very heart of those valuable countries, Ruanda and Urundi.

Should a branch be possible up the Ruvuvu River to Usumbura and Tanganyika, then the whole problem is satisfactorily solved. We have direct lines opening up Lakes George, Edward, Kivu, and Tanganyika to Victoria, and all those valuable estates Nos. 5, 6, 7, 8, 9, 10 and 11 are provided with a chance of direct import and export with Great Britain. I had written this paper before I had seen the February number of the *Geographical Journal*. Captain Phillips's most valuable information published in this paper appears to bear out most of these suggestions.

Many German colonial experts are enthusiastic about a railway line from Moschi to Aruscha and on to the Victoria Nyanza. They did not agree as to the best route and admitted that much of the country traversed was waterless and uninhabited. Moschi is, however, now connected with the Mombasa Railway. No doubt a short and strategically useful line might be constructed to the southern end of the Victoria; in times of peace also a competitive route to Tanga would no doubt relieve the Mombasa-Victoria line, which has even now more traffic than it can carry.

But any line to the Victoria should be well within British territory, and not on the other side of the frontier.

There is, however, no connection between Lake George and Lake Albert. There can hardly be very much difficulty, except a large number of bridges, in constructing a line from Lake George towards or near Fort Portal, but from this place there is a very steep descent to the shores of Lake Albert. The Wasa River may, however, afford a possible route.

Should these connections be made we have a real Cape to Cairo line in the sense in which it was understood by Cecil Rhodes.

With regard to this sound business proposition, which has been libelled as a "phrase" or "ideal," I venture to suggest that the insight and genius of Cecil Rhodes have been amply justified by the results of the last few years.

Had the Cape to Cairo line been built when he first suggested it, there would never have been a German East Africa in a military sense.

Had it been in existence in 1914, thousands of lives, not to speak of many millions of money, would have been spared, for Von Luttow

* "It is protected against eastern and south-eastern gales."—G. J. Delmé Radcliffe, December, 1905.

Vorbeck could not possibly have maintained himself for so long a period.

Indeed, I venture to suggest that the extra millions wasted through the protracted resistance in East Africa would have built the railway ten times over.

Rhodes, moreover, was a man of business. He realised, and I am sorry to say his critics did not then and do not now understand, that it is only in British territory that our exports have fair play and only from British ports that raw materials have a chance of coming to our shores.

He also foresaw (and Rhodesia has abundantly justified him) that starting from the great ever-expanding markets of the Transvaal, the true line into Africa is by the Rift Valley, or rather along the healthy highlands bordering it.

The expansion of Rhodesia surely proves that his view was correct.

By the scheme outlined there are some half-dozen areas as promising or even more promising than British East Africa used to be some twenty-five years ago.

The failure to carry through Cecil Rhodes's "ideal" at the time when it was suggested appears to me to have delayed the development of Africa for a quarter of a century.

Against the scheme to-day, I find usually the same arguments that were used then.

First, the "breaking of bulk" at every change from rail to steamer; I have been informed that breaking-bulk used to cost about 2½d. per ton in the Sudan.

Secondly, that lateral railways should be built by the quickest possible route to a seaport. Those who allowed the Cape to Cairo line to be side-tracked on account of this argument should have seen these east–west lines carried through at once, specially that to Nyasa, which is not even finished to-day.

This objection, however, falls to the ground in any case, for the system here suggested provides direct access to all the African lakes as well as the essential and necessary north-to-south line.

The cost of these railways will, of course, be very considerable.

The following table gives the approximate cost per mile of various African railways. Most of it is taken from German sources (Baltzer, *loc. cit.*), and it must only be considered as approximate, that is, as a rough guide as to what may be expected.

RAILWAY TABLE.

Length. Miles.	Nationality.	Name.	Passenger kilometres (millions).	Tons. Kilometres.	Cost per mile.	Excess Receipts over Expenditure.
					£	£
26	German	Togo Coast			2,124	
	German	South-West Africa (lowest)			3,000	
75	German	Togo Inland			4,085	
102	German	Togo Hinterland			4,108	
223	British	Sierra Leone			4,320	22,000
113	French	Ivory Coast	3·8	2	5,069	
	French	Dakar St. Louis	32	22·5	5,400	90,160
90	British	Magadi			5,914	
2,500	British	South Africa Company			6,000	
368	French	Konakry Karussa	8·6	6	6,195	92,000
346	French	Upper Senegal	6·6	8	6,300	
	French	Guinea			6,437	60,000
273	German	Tanga Aruscha	13·6	3·2	6,630	11,000
782	German	Midland Tanganyika	22·3	6·5	7,966	75,000
	German	South-West Africa (Upper Limit)			8,000	
100	German	Kameruns (North)			8,046	
300	German	*Estimate* Tabora-Kageraknee			8,368	
76	British	Lagos Ibadan			8,595	
114	British	Nyasaland, Port Herald to Blantyre			8,771	
618	British	Uganda Railway			10,513	209,000
171	British	Gold Coast, Sekondi			10,943	165,000
261	Belgian	Congo	7		13,200	
176	German	Kamerun Midland			13,711	

Herr Baltzer (Die Kolonial-Bahnen, Berlin. 1916) states that the shareholders of the Matadi Leopoldville Railway, in the Belgian Congo, received a dividend of 19 per cent. The Otavi Railway in 1912 gave a return of 9·95 per cent. I think, in 1911, the Nigerian Railway gave a return of over 4 per cent on the capital expended.

The data (except Uganda Railway) refer to the years 1910 to 1912. The net earnings of the Shiré Railway were £281 per mile in 1917

and £292 in 1918. Marks were reckoned at twenty and francs at twenty-five to the pound sterling.

This system, which will open up practically one-third of the Continent of Africa to British trade, may be taken as follows :—

		Miles.	
Southern Section	1. Kashitu—Kasama—Kituta—Abercorn	600	800
	2. Abercorn—Karongas	200	
	3. Luchenza—Malindi (Nyasaland)	(133)	
	4. Trans-Zambesia	(165)	
Central Section	1. Tanganyika to Kaseke	100	541
	2. Kaseke to Kivu	137	
	3. Kaseke to Kakitumbo	100	
	4. Lake Karenge—Lake Edward	60	
	5. Lake Karenge—Kagera Mouth or Mizinda	144	
Northern Section	1. Lake George *viâ* Fort Portal—Lake Albert	75	275
	2. Lake Kioga—Butiaba	100	
	3. Nimule—Rejaf	100	
	Or leaving out Southern Section, Nos. 3 and 4, a total of	1,616	

A special survey would, of course, be necessary before any one of them can be recommended. Mr. Wilson-Fox estimates for the Southern Section £6,000 a mile. One might take for the Central Section, say, £7,500 a mile, and for the Northern Section, say, £7,500 for No. 1 and 2, and £6,000 for No. 3.

During my service in the Egyptian Campaign I had frequent opportunities of observing the manner in which the Egyptian Labour Corps made a railway seem actually to grow before one's eyes. If it were possible to use Egyptian labour for the third line of the Northern Section I believe the cost would be far less even than £6,000 per mile. Their methods were practically those employed by their forefathers at the construction of the great Pyramid, but the rapidity and efficiency of the work done was beyond all praise.

The only lines on which there might be such difficulties as were encountered on the Uganda Railway are Central Section No. 1 and Northern Section No. 2.

The total capital required would then appear to be somewhere about £10,170,000, to which £1,000,000 for repairs to the Uganda line must be added.

As to the prospects of dividends, I have already given a few details of the railway earnings in various parts of Africa.

These show that there is hardly one of these railway lines that is not either already a paying affair or may be with reasonable probability soon expected to become remunerative.

Or, one may take it from another point of view, by considering the total imports and exports and their rate of growth.

From the general point of view, prospects are surely promising enough.

The Central Section in particular will open up a huge district with a population nearly as large as that of Scotland, and with a considerable trade already established.

The Northern Section has one known and valuable goldfield, and will assuredly open a further large cotton field. North (No. 3) is the only line of which at present the commercial prospects are a little obscure (see below).

		Imports. £	Exports. £	Total. £	White population.
British East Africa	1913–14	2,148,000	1,483,000	3,631,000	
„ with Uganda	1917–18	2,810,000	1,742,000	4,552,000	6,132
Nyasaland	1913–14	189,000	201,000	390,000	
	1917–18	354,000	157,000	511,000	731
Rhodesia South	1918	2,957,000	5,254,000	8,211,000	30,000
„ North	1917	356,000	343,000	699,000	2,165
German East Africa	1913	2,668,000	1,778,000	4,445,000	5,336

There are two or three special and particular prospects which should be mentioned.

Large supplies are required by the many missionary stations, and no doubt such stations will increase in number as well as in influence with the railways.

The tourist traffic by a real British Cape to Cairo route will surely be considerable. Ruwenzori and Mfumbiro are much more interesting as a tourist resort than modern Switzerland.

Then, also, a through route by rail and steamer would bring pilgrims direct to Jerusalem and Constantinople as well as to Medina, *en route* for Mecca.

There are many Mohammedans in Central Africa, and a large number will certainly undertake the Mecca pilgrimage when it can

be properly arranged. It is not possible at present.

In addition, there is the Government traffic, which is sure to be considerable. I regard those four sources, missionary, tourist, pilgrim, and Government traffic, as affording an immediate revenue, so that from the purely dividend-earning point of view the prospects are sound. But that is not by any means all that there is in it.

To the British working-man these railways are of immediate and vital importance. Our trade in cotton, and its manufactures, means at least £100,000,000 a year. I need hardly enlarge on the danger in which this great industry lies. It is up to us to produce somewhere in the Empire all the cotton we require. The production of America is annually less, and annually more and more swallowed up by increasing manufacture in the United States. The British Cotton Growing Association are making splendid efforts to drive this point home to the comprehension of the working-man, and I need not enlarge on it. Without criticising Government in the past (which I have studiously avoided) I venture to put a question which requires explanation :—

Seeing the importance of encouraging cotton cultivation, why did the Uganda authorities impose an export tax of £1 per bale on cotton?

Here in these railways to Nyasa, and from Victoria to Tanganyika, Albert and Kivu lies the present opportunity for Britain.

Almost as important is the question of oil seeds and feeding-stuffs. The prices of feeding-stuffs are at present enormous. It is to this, in large part, that is due the high price of eggs, of bacon, of milk, butter, and cheese. Ground-nut cake, *e.g.*, costs the British farmer £24 10*s*. per ton, cotton-seed cake £27 10*s*., and bean meal £27 per ton.

In all these new districts there is a practically limitless field for beans and peas, ground-nuts, gingelly or beniseed, for maize, as well as for rice, wheat, and oats. I am only mentioning a few of the more important products in which, as a practical farmer, on a very small scale, I am deeply interested.

The other side of this question is just as important. The whole of these countries form an ever-expanding market for manufactured articles of every sort. Cotton cloth is in most parts of Africa the chief article of import, but it is in the thousand-and-one articles of European make that the opportunity for the British manufacturer is at present open.

It seems to me that there will be the severest possible competition for this hardly tapped and practically inexhaustible market during the next few years. Japan, Germany, Belgium, and other countries are alive to the possibilities of Africa.

I have never been able to understand why the British working-man takes no apparent interest in this question of African development, for his existence as such in Britain depends upon it.

As regards the native himself, the more Africa falls to the guidance and control of the British, the better off he becomes. If European control were removed, then there would be *at once and within one generation* an immediate relapse to the horrors of the slave trade and the devilish cruelties of the native chiefs. When our officers first visited the Awembe country, many people, some mere children, were found with ears, lips, noses and hands cut off.

The population of the Anglo-Egyptian Sudan dwindled from 8,000,000 to 1,800,000 through massacre and famine during the occupation of the Dervishes.

Under British control, the natives in Africa are increasing in number; they are becoming more prosperous and learning the salutary lessons of civilisation.

In a British Capetown to Cairo line we have perhaps the most splendid opportunity that has ever been placed before any nation on the face of the earth. All along it there are fine healthy ridges and plateaux. There missions can be established, and from them Christianity can permeate and penetrate the whole of Africa; a string of bright stars will shine out along the entire length of the Dark Continent.

From the point of view of security and strategy alone, a Cape to Cairo line of communication is an absolute necessity; surely the bitter experiences of the last few years have abundantly proved this. Abyssinia lies to the east and north of it, and the Sudan and Uganda must be in the closest possible touch.

Although everybody must admire the enterprise and courage displayed by the Government in establishing an air route along the Cape to Cairo line, I feel that while these stations will be strategically of infinite importance, they are hardly yet of great commercial value. If every aëroplane requires four mechanics, and petrol has to be supplied in quantity, it is clear these stations will involve a very large extra traffic.

If, as appears from the most recent announcement of Government intentions, Ruanda and

Urundi are to be handed over to Belgium, and if the Congo Free State or Belgium is to have an *enclave* at the Port of Dar es Salaam, then the construction of these railways is even more urgently necessary. Otherwise, all the trade from this port, inwards and outwards, will go to Belgium, or more probably to Germany.

It is really impossible to quote all who have written on this question, but I wish specially to mention Sir Alfred Sharpe, Sir Harry Johnston, Sir Charles Metcalfe, Mr. MacCarthy, Mr. H. Wilson-Fox, Colonel Delmé Radcliffe, the late Colonel E. A. Steel, Major Grogan, Major Bright, Major Cuthbert Christy, and the late Captain Leeke, to whose works I am greatly indebted. I have also to thank the Royal Geographical Society for the loan of maps and lantern-slides.

DISCUSSION.

The Chairman (Sir Thomas H. Holdich), in opening the discussion, said that the author was to be congratulated on having read a very useful and interesting paper. He had not wandered into any flights of fancy with regard to the aeroplane, as he might have done, because he was as convinced as he (the Chairman) was, that it would be many a long year before aeroplanes could be brought into any kind of competition with railway traffic for commercial business. Those present would have observed from the paper that there had lately been a good deal of controversy on the subject of railways in Africa, particularly at the Geographical Society. Mr. Wilson-Fox had recently made a rather startling proposal about a railway from Beira to Cairo, his idea being that the communications between those places should be connected by rail-ferries on the lakes, and in that way a great deal of railway construction would be avoided. For practical reasons, however, that idea did not find very much favour. He thought one could not do better than accept the author's division of the country into three districts, the south, the centre, and the north, and confine one's attention generally to what was wanted in each. Anyone, by looking at the map, could see at once that railway problems in the south-east were very far forward. There had for many years been one gap between Beira and the Zambesi, but that was rapidly being filled in. In the south-west, however, there was no communication between the Transvaal and the western coast, and he had often been surprised that no such communication had yet, so far as he knew, been suggested. He thought use might be made of Walfisch Bay for a much closer and more direct communication with Pretoria. On the north one was faced with the everlasting choice between a direct line following the Nile Valley and the detour, which had already been commenced to a certain extent, from Khartoum to Obeid and Fasher, then turning southward and leading up to the Nile-Congo watershed, which the author had called "Christy's Highlands." That would cover a very large amount of country which appeared to be particularly suitable for railway construction, not only on account of the physical character of the country, but from the character of the inhabitants. If that plan was carried out, he could not help thinking that the railway forecasted by Dr. Christy, through Belgian territory along the Congo from Stanleyville to the head of the Northern Rhodesia Railway, would be the first opening of a direct line from the Cape to Cairo. Although he personally had no acquaintance with any of that part of Africa, he had had the opportunity, from the highlands of Abyssinia, of looking over the stretch of broken hills and lowlands which flanked Abyssinia on the west and formed the western revetment of the Abyssinian plateau. From the very limited view he had of it, it certainly appeared to be most unpromising country, and he could not believe, on account of the enormous amount of bridging that would be necessary, that it would ever be possible to bring a line from the Cape to Uganda to the east of the Nile. With regard to Central Africa, the author's third division, that was the crux of the whole position and the kernel of everything connected with future developments in Africa. He had formed no opinion at first hand with regard to the matter, but he thought that the railway connection through all that part of the country contained so many isolated plateaux and highlands entirely favourable for European occupation that it was inevitable that eventually the general line of communication would not be either north to Cairo or south to the Cape or Beira, but to the east, and that the outlet for the central trade would be found on the east—it was to be hoped as soon as possible, because if the outlet was found on the west it would be simply putting the trade into the hands of the Belgians. Although he had not had the opportunity of working professionally in Africa, he had worked in very rough country on the north-west frontiers of India with a view to railway developments, and, so far as he knew, in every case where a railway survey had been made purely for the purpose of alignment, without waiting for a general geographical map of the whole district to be made and put into the hands of the engineers before they commenced the work, a line had been chosen which would not have been chosen if a geographical map had been available at the time. Such a map, which was quite large enough if made on the scale of four miles to the inch, should be made before anyone became obsessed with the idea that any one particular line was the only line to follow; otherwise the engineers engaged in the work could not tell what physical difficulties they might have to encounter, or what the prospects of traffic would be on alternative routes. There was no such map of Central Africa at the present time, but he hoped it might soon be obtainable.

SIR ALFRED SHARPE, K.C.M.G., C.B., said the author had spoken of the Cape to Cairo railway. He thought possibly he might have had him in mind, as he had expressed opinions at one time and another regarding this project. He had never wished to depreciate for a moment the value of a railway through from the Mediterranean to Cape Town; from a strategic point of view alone it would be of enormous value. What he had always said, however, was that the magnificent countries lying along what might be called the backbone of Africa required first of all outlets to the nearest ports on the sea coast. He had not the slightest doubt that the Cape to Cairo through route would eventuate of itself in a very short time, by the inter-connection of the present railways one with another and with the great lakes. The author had shown where the natural trade outlets would be—Beira for practically all Rhodesia, Nyasaland and Zambesia; Dar es Salaam for the Tanganyika territory; and Mombasa for Uganda, British East Africa, and no doubt a considerable extent of the eastern part of the Belgian Congo. He would like the author to say whether his scheme and all the other schemes being put forward at present were based on the idea that this country was ever going to give German East Africa back to Germany. He had never contemplated before that Germany's African territories would be returned to her. If they were, then our railway schemes in Africa would have to be arranged so that we could bring all the trade to our own ports; if not we could simply bring it to the most convenient ports. The paper had been one of the very greatest interest, and was the most lucid description of the conditions governing the development of Central African territories to which he had ever listened.

ADMIRAL THE HON. SIR EDMUND FREMANTLE, G.C.B., said he would not attempt to go into the geographical or commercial details with which the author and the Chairman had dealt, but wished to strike a personal note. He had the pleasure of meeting the author about thirty-two years ago in Madagascar, where, if he recollected aright, Mr. Scott Elliot was practically marooned through an outbreak of smallpox, and he took him, in the flag ship, from there to Zanzibar, from which place he was able to conduct further investigations into the subject on which he was then engaged. That was to a certain extent a proof of the great length of time during which the author had been studying Africa and his competence as an African observer. Another proof of that was to be found in the exceedingly able and interesting paper that had been read that afternoon.

MAJOR E. H. M. LEGGETT, R.E., D.S.O., in moving a vote of thanks to Mr. Scott Elliot for his very illuminating paper, said he was sure the large number of people throughout the world who would read the paper when published in the Society's *Journal* would feel their indebtedness to the author as much as did those present at the meeting. He had undoubtedly made an important contribution to the great Imperial problem of communications throughout Africa, in which country England was fortunately pre-eminent. He would not attempt to follow the author into his magnificent visualisation of the future or to discuss with him the many routes which he knew Mr. Scott Elliot himself would be the first to admit were open to discussion, but there was an aspect which overshadowed all the pros and cons of this or that proposition, and that was the intense Imperial need for the development of Africa. Its potentialities as a producer of raw material and as a consumer of British-made goods must be developed, and, as the author had said, Africa was a country in whose future the British working-man had a stake which could hardly be overestimated. The author had laid stress on the point that there must be no links missing in the chain of communications. The first great link was that of the ocean—the ocean was the Imperial line of communication with all the world. Then, as this country commanded the ocean, it must consider how it could get from the ocean on to the mainland, and that was a point he hoped the author would deal with on a future occasion—the harbours. Harbours were essential in the Empire trade routes, and needed the attention not only of thinkers and travellers but of statesmen and business men. It was easy to waste large sums of money in squeezing through a bottle-neck harbour, and the trade, both import and export, which spent those large sums hardly knew why it was suffering from such a tax as was imposed by anything that was not fully efficient in the working of the harbours, which gave the access from the sea to the land. Another point which the author might deal with in a future paper was the question of whether the existing railway lines were capable of carrying the traffic which was now developing so rapidly. It was obvious that the extension of railway lines was so necessary that the great strategy of railway development throughout Africa should be taken in hand, but he would suggest that in the conduct of all affairs both strategy and tactics were required. Strategy without good tactics might fail, and the tactics of traffic were the efficient conduct of the minor details. He therefore suggested that the existing lines needed a very thorough inspection and overhaul, and a calculation as to whether they were equal to the traffic of the next two or three years. The events that occurred during the next two or three years in the great African territories would have a bearing on the financial success and even on the prospect of obtaining the strategic lines of communication of the future, because it was existing lines which gave confidence to capital and to Governments by the earning power which they showed. Their earning power had hardly yet begun to be developed, and with comparatively small outlays the earning power of the existing lines could be quadrupled, or multiplied to an even greater extent than that. After the five years of war, during which they had

necessarily passed through a period of deterioration, without the opportunity of being kept up to their pre-war standard, the railways of Africa now had to cope with a far greater traffic than before the war; and he suggested they should be thoroughly overhauled, and that in discussions such as the present one, where the great future before Africa was dealt with, no one should forget or gloss over, or allow those who controlled money or Governments to forget, that the existing lines must be kept up to date and even ahead of the traffic they were at present carrying.

MAJOR H. BLAKE TAYLOR, in seconding the resolution, said that, as a former General Manager of the Uganda Railway, he could endorse the remarks Major Leggett had made as to the very great necessity of keeping the railways up to the full carrying capacity to meet the rapid development of the country. Many parts of East Africa and Uganda were developing trade far beyond that which the railways were now fit to carry, and that applied also to Africa generally. He agreed with Sir Alfred Sharpe that traffic would go to the nearest port, and any attempt to divert to Mombasa traffic the natural outlet of which was at Dar es Salaam would absolutely fail—it would not be economic. He also agreed with Sir Alfred that Germany's African colonies should not be returned to her.

The vote of thanks was carried unanimously.

MR. SCOTT ELLIOT, in reply, said he was not afraid that German East Africa would be given back to Germany, but what he was afraid of, was that the trade of German East Africa would go back to Germany. That was the important point. With regard to trade outlets, it would be found that the railway scheme he had drawn up gave the shortest route to the coast, although it did not go to Dar es Salaam. It provided quite as short a route from Central Africa to the coast by going to Mombasa as it would if it went to Dar es Salaam.

The meeting then terminated.

GENERAL NOTES.

STAINED GLASS AT THE VICTORIA AND ALBERT MUSEUM.—The Victoria and Albert Museum has lately received two important loans of stained glass. The first, lent by Mr. William Burrell, comprises five panels of French sixteenth-century work that were at one time in the collection at Costessey Hall, Norfolk. Two of these are from a "Tree of Jesse" window of the early part of the century. The remaining three, representing scenes from the life of St. John the Evangelist, with figures of the donor and his family kneeling below, may be assigned to the year 1530 or thereabouts. They are all five thoroughly characteristic examples of late French Gothic glass, showing great skill in the balance and harmonising of the colours. The second loan, from Mr. George Eumorfopoulos, consists of two specimens of English work of the fifteenth century. One, a panel representing St. George, and formerly in the collection of the late Mr. Lewis F. Day, belongs to the first quarter of the century. The other, a roundel of the Annunciation, and formerly at Ditton Park, Bucks, is slightly later in date, and was probably made about 1450. It is a charming piece of work and thoroughly English in character.

CAROLENE GAS.—A new gas, to take the place of acetylene in blow-pipe work, has been produced in America. It is called carolene, and, according to the *Engineer*, is said to have a thermal value of 1,580 British thermal units per cubic foot. The composition is 84 per cent. carbon and 14 per cent. hydrogen, and as the gas can be safely stored in unpacked cylinders at a pressure of 3,500 lb. per square inch, a considerable saving in weight can be effected. The maximum temperature obtainable is put at 6,200° F.

RAILWAY ELECTRIFICATION IN ITALY.—According to *La Tribuna*, the work of the Commission for the electrification of the railways, appointed by the Minister of Transports, is proceeding actively. The Railways General Management are continuing the electrification, on the three-phase system, of the line between Turin and Genoa of about 400 kilometres, and by means of a private undertaking the lines Turin-Milan and Milan-Voghera for another 200 kilometres, in order to complete as soon as possible the principal links of this system. With regard to central Italy, a meeting was held recently, under the presidency of the Minister of Transports, between the various public bodies and companies interested in the utilisation of the electric power in the Umbro-Tuscan-Emilian district, in order to co-ordinate available power for local requirements and railways. The Commission approved plans for two thermo-electric stations at Tavernelle di Perugia and Torre del Lago, capable of producing about 20,000 kilowatts per hour. Plans have been started for linking up Rome and Naples with the southern provinces. A programme has also been drawn up for the extension of steam traction by oil fuel for those lines where it will take some time to provide hydro- and thermo-electric power, that it is to say, largely in Sicily, Calabria, Basilicata and Puglia.

PALM SUGAR IN BRAZIL.—In common with many other palms, writes the United States Consul at Rio de Janeiro, *Nipah fructificans* contains sugar in quantity sufficient to make its extraction a commercial success. It is estimated that at least 12 per cent. of sugar could be recovered from the sap, and that an average annual yield of 4,000 gallons of sap per acre would yield 4,000 lb. of sugar. This palm is found in great numbers in Borneo. In Brazil, in the Amazon basin, the Indians prepare for their feasts and

pow-wows a beverage from the sap of a great number of palms, but it is not known to what species these palms belong, or if any experiments were made to determine their sugar content. Rubber cutters and travellers agree that "palm wine" is very refreshing as long as too strong a fermentation has not set in.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday afternoons, at 4.30 p.m. :—

April 14.—Joseph Thorp, "The Fundamental Basis of Good Printing." Sir Herbert Morgan, K.B.E., will preside.

April 21.—Air-Commodore Edward Maitland, C.M.G., D.S.O., A.F.C., "The Commercial Future of Airships."

April 28.—Brigadier-General Charles H. Sherrill, LL.D., "Ancient Stained Glass." The Right Hon. Lord Desborough, K.C.V.O., will preside.

May 5.—Dr. C. E. Kenneth Mees, "A Photographic Research Laboratory." Sir Henry Trueman Wood, Chairman of the Council, will preside.

May 12. — Graily Hewitt, "Rolls of Honour."

May 19. — John Somerville Highfield, M.Inst.C.E., M.I.E.E., "Electrical Osmosis." Alan A. Campbell Swinton, F.R.S., will preside.

Indian Section.

Thursday afternoon, at 4.30 p.m. :—

April 15.—Sir Geo. Cunningham Buchanan, K.C.I.E., M.Inst.C.E., "The Ports of India: their Administration and Development." The Right Hon. E. S. Montagu, M.P., Secretary of State for India, will preside.

Thursday afternoon, at 5 p.m. :—

May 20.—Brigadier-General Lord Montagu of Beaulieu, C.S.I., "Roads and Transport in India."

Monday afternoon, at 4.30 p.m. :—

May 31. — Albert Howard, C.I.E., M.A., A.R.C.S., F.L.S., Imperial Economic Botanist to the Government of India, "The Improvement of Crop Production in India." Sir Robert W. Carlyle, K.C.S.I., C.I.E., will preside.

Date to be hereafter announced :—

Sir Valentine Chirol, "The Enduring Power of Hinduism." (Sir George Birdwood Memorial Lecture.)

Colonial Section.

Friday afternoon, at 4.30 p.m. :—

May 28.—Professor William A. Bone, D.Sc., Ph.D., F.R.S., "Lignite."

Indian and Colonial Sections.

(Joint Meeting.)

Friday afternoon, at 4.30 p.m. :—

June 4. — Professor Sir John Cadman, K.C.M.G., D.Sc., F.G.S., M.Inst.C.E., "The Oil Resources of the British Empire."

Cantor Lectures.

Monday evenings, at 8 p.m. :—

Walter Rosenhain, B.A., D.Sc., F.R.S., Superintendent, Department of Metallurgy and Metallurgical Chemistry, National Physical Laboratory, "Aluminium and its Alloys." Three Lectures.

April 12, 19, 26.

Arthur Thomas Bolton, F.R.I.B.A., F.S.A., Curator, Soane Museum, "The Decoration and Architecture of Robert Adam and Sir John Soane, 1758–1837." Three Lectures.

May 3, 10, 17.

MEETINGS FOR THE ENSUING WEEK.

Wednesday, April 7...Public Analysts, Society of, at the Chemical Society, Burlington House, W., 8 p.m.

United Service Institution, Whitehall, S.W., 3 p.m. Lieutenant W. S. King-Hall, "Submarines and Future Naval Warfare."

Royal Archæological Institute, at the Society of Antiquaries, Burlington House, W., 4.30 p.m. Dr. A. V. Peatling, "Mediæval Glass in Surrey Churches."

Sanitary Engineers, Institute of, 296, Vauxhall Bridge-road, S.W., 8 p.m. Captain A. F. Girvan, "Modern Development in Civil and Military Water Supply."

Thursday, April 8...Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m.

Historical Society, 22, Russell-square, W.C., 5 p.m. Miss M. Dormer Harris, "Unpublished Documents relating to Town Life in Coventry."

Friday, April 9...London Society, at the Royal Society of Arts, John-street, Adelphi, W.C., 4.30 p.m. Miss Amelia Defries, "Art and the City."

Cyclist's Touring Club, at the Royal Society of Arts, John-street, Adelphi, W.C., 8 p.m. Annual General Meeting.

Astronomical Society, Burlington House, 5 p.m.

Auctioneers and Estate Agents' Institute, 34, Russell-square, W.C., 7.45 p.m. Sir H. Trustram Eve, "Village Reconstruction."

Concrete Institute, 296, Vauxhall Bridge-road, S.W., 6 p.m. Mr. T. J. Clark, "The Uses of Concrete."

Correction.—In a General Note on "Flax Culture in Russia" in the *Journal* of March 19th, 1920, page 298, col. 2, the following sentence occurred: "The average yield to the acre for Russia was only 300 tons as against 400 to 700 tons to the acre for other countries." For the word "tons" in each case the word "pounds" should be substituted.

Journal of the Royal Society of Arts.

No. 3,516. VOL. LXVIII.

FRIDAY, APRIL 9, 1920.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICE.

NEXT WEEK.

MONDAY, APRIL 12th, at 8 p.m. (Cantor Lecture.) WALTER ROSENHAIN, B.A., D.Sc., F.R.S., Superintendent, Department of Metallurgy and Metallurgical Chemistry, National Physical Laboratory, "Aluminium and its Alloys." (Lecture I.)

WEDNESDAY, APRIL 14th, at 4.30 p.m. (Ordinary Meeting.) JOSEPH THORP, "The Fundamental Basis of Good Printing." SIR HERBERT MORGAN, K.B.E., will preside.

THURSDAY, APRIL 15th, at 4.30 p.m. (Indian Section.) SIR GEORGE CUNNINGHAM BUCHANAN, K.C.I.E., M.Inst.C.E., "The Ports of India: their Administration and Development." THE RIGHT HON. E. S. MONTAGU, M.P., Secretary of State for India, will preside.

Further particulars of the Society's meetings will be found at the end of this number.

PROCEEDINGS OF THE SOCIETY.

TWELFTH ORDINARY MEETING.

WEDNESDAY, MARCH 3rd; BRIGADIER-GENERAL SIR PERCY SYKES, K.C.I.E., C.B., C.M.G., in the chair.

THE CHAIRMAN, in opening the meeting, said he had never had the privilege of visiting Mongolia, but some years ago, when he was Consul-General in Chinese Turkestan, he was told that Mongolia was in his district and he was very anxious to go and see it. He found, however, that the capital of Mongolia was just 2,000 miles from where he was living, and as one could only travel at the rate of about a hundred miles a week it would take him twenty weeks to do the journey, so he did not go. Mr. Garnett, who was to read the paper that afternoon, had enjoyed exceptional opportunities of studying Mongolia. He had travelled in the country for seven months and had the additional advantage of being in touch with the authorities, so that he was able to learn a great deal more about the country than an ordinary traveller could possibly do.

The paper read was—

MONGOLIA FROM THE COMMERCIAL POINT OF VIEW.

By WILLIAM JAMES GARNETT,
First Secretary, H.B.M. Diplomatic Service.

To estimate correctly the value of any country from the point of view of commerce it is essential first to understand the customs, mode of life, geographical features and administration of that country; and it is with those objects in view that I have constructed this paper this afternoon. There is no time to give any historical account of the people who inhabit that vast region known as Mongolia, although such a history embraces as long a period and as wide an extent of the world as that of Rome herself, and has had as profound an effect on the destinies of the human race, including the European nations. My knowledge of the country is derived from a seven months' journey made in 1908—mostly on camelback—and, though it may be thought out of date to-day, let me say that were the great Genghiz and Kublai to arise from their graves to-day they would find their country and their countrymen much as they left them. The circumstances prevailing, therefore, in Mongolia at present are substantially the same as prevailed in 1908.

Upon the overthrow of the Mongol Empire in China by the Ming dynasty in 1368, the tables were turned, and Mongolia was invaded and conquered by China, the Mongols were pushed back to their original home in the Kerulon and Orkhon valleys and never again appeared in any strength south of the Gobi, except to establish themselves in the Ordos. The energetic

Chinese of North Shansi and Chihli gradually pushed back those few Mongols who did take advantage of the weakness of the Ming dynasty to establish a footing south of the Gobi, and gradually absorbed the fertile plains right up to the foot of the plateau. They also crossed the Gobi and established trading centres in North Mongolia, at Urga, Uliassutai and Kobdo, and solitary Chinese traders may also be found at occasional Mongol camps along the tracks across the deserts. Early in the present century the Chinese Government appear to have desired to extend this colonisation process, and instructed their representatives to "open up" their land to Chinese colonists. The Governor of Uliassutai informed me that there was no land suitable for farms in his province. This was, however, quite incorrect, for there are a quantity of well-watered districts in that province which could support a large population, and where wheat, kaoliang, millet, etc., could be grown. An official was also sent to the Altaishau to construct the new colony of Sharasumé.

The Russian Government demanded the maintenance of the *status quo*, the first effect of which was that the North Mongol princes fell increasingly under Russian influence, the second effect being that these princes asked for independence from China. This led to the Kiakhta Convention, which did not mean that Mongolia was fit to govern herself, but that Russia "*drang nach Osten*" was temporarily irresistible. With the complete collapse of the Russian Empire the situation was bound to revert to that which existed before the Kiakhta Convention, and that is what has occurred.

Kalgan is, as you know, the main south gate to Mongolia; but there is another town, Kweihuacheng, farther west which will rival it when railway, road, river, and postal facilities are forthcoming, for Kweihuacheng, in addition to its favourable geographical situation between Mongolia and Shansi and Shensi, also taps the fertile Yellow River strip on the left bank of that stream from Ninghsia, very little use being made yet of the Hoangho for transport of goods from that last-named place. There are several ferries across the Hoangho, and we crossed by flat barges to the south-west of Kweihuacheng, continued south-west through the Ordos as far as the Great Wall, and, turning north-west, crossed the stream again close to Ninghsia. The Ordos district is most unattractive; it is an inhospitable sand-swept country, lying in a loop formed by the Yellow River and bounded on the south by the Great Wall; it consists of rocky ravines and sandy plains, with a few secluded fertile valleys; there is a great deal of drift sand; for pasturage there is a certain amount of thorny scrub and thin grass. The entire district is useless for colonisation, and there are practically no Chinese to be found, though a few are engaged in extracting salt from the numerous lakes of varying size. The seven Mongol princes who rule the district have no importance. Should, however, a venturesome traveller cross their difficult stretch of land (by camel, for there are no roads) he will receive a warm welcome from the Roman Catholic missionaries at Borobalgasson and Hsiao-chiaow-pan.

Ninghsiafu lies in a most remarkably well-cultivated area. From the very banks of the Hoangho the ground is covered with thick grass and carpeted with flowers. There are groves of trees and villages at every turn. The whole aspect of this bank of the Hoangho is in marked distinction from that which we had left, which was brown, sandy, bleak, desolate, treeless; and there is no reason why Ninghsia should not become a centre for Mongol trade, for it is only two days by camel across the Alashan Mountains to Dinyuaning, the capital of the Mongol kingdom of Alashan. From Dinyuaning a track runs across the desert to Uliassutai, through one of the most difficult parts of the Gobi, it is true, yet one which is used by Europeans, for at Dinyuaning I met Colonel Kozloff, the Russian explorer, who had just crossed by this route.

Alashan, though nominally Mongol, has fallen much under the influence of Peking, through a succession of Manchu consorts for the Alashan sovereigns. There was therefore a prosperous Chinese trading colony, and their intercourse with the Mongols has had a civilising effect on the latter. I noticed many cheap Japanese goods at Dinyuaning, and the room of the son of the reigning sovereign was littered with cheap clocks, watches, gaudy tablecloths, rugs, pictures and mirrors.

Returning to Kweihuacheng, partly along the fertile Yellow River strip and partly across the north portion of the desolate Ordos, we prepared to cross the Gobi to Urga.

I understand that nowadays the Gobi can be crossed, from Kalgan at any rate, by motor-car in four to six days; but no such convenience existed in 1908, and we made use of the Tai-lu or official track across the desert, changing our camels for fresh ones every twelve miles or so at a Mongol camp where Government has

stationed animals for the purpose. Although one thus always finds Mongol tents at which to sleep, it is necessary to carry tents (and even water) for a journey in the Ordos or in other parts of Mongolia than the Gobi. At these camps there is always a well (there is no surface water in the Gobi until the Khangai Mountains are reached) and the inevitable mutton to eat.

There is an impression that the Gobi is a sandy desert. That impression is wholly incorrect, for between Kweihuacheng and Urga one does not come across a single stretch of sand. On the contrary, the ground is entirely covered with a thin short grass, which forms abundant pasturage for the tribes. But a camel journey across this part of the Gobi is inexpressibly dreary. You can travel for fifteen days without seeing a single tree, nor any cultivation, nor bird life, nor, except at the midday halt to change animals and again at nightfall does one see any Mongol encampment. The surface of the ground is flat or at the most only slightly undulating, and the gravel track can, as a rule, be seen for miles ahead. Nor does one meet any other travellers, except very occasionally a mob of thousands of sheep or ponies going to market in China.

The journey from the Kweihuacheng plain on to the plateau of Mongolia can be made by cart, and it is interesting to note the quantity of beans, wheat, wool, etc., coming down, and to what extent the Chinese have cultivated the fringe of the plateau. There has, however, been no extension of this colonisation since 1872, for the same Chinese settlements noted in that year by Ney Elias, namely, Kokoillikung and Sanyuyuan, still remain the advance guard of Chinese progress in this direction.

And so we reached Saire Ussu (gravelly water) where the tracks to Urga and Uliassutai fork, and two days later were in hilly country again, hilly, yes, but still treeless until the wooded heights of the Bogdo Ula, south of Urga, come in sight.

Just before reaching Urga the River Tola has to be forded, and as this was in full flood a week later on account of heavy rains, a small cart bought at Urga was entirely submerged. I am therefore curious to learn how the Kalgan-Urga motor services manage this last lap into Urga.

Urga is the largest of the North Mongolian settlements, and is the only one which appeared to be at all thriving in 1908. The plain was full of yourts (the felt-covered Mongol tent), there were great quantities of sheep, goats, etc., everywhere, and Mongol horsemen and horsewomen were galloping about in every direction. The many temples seemed to be much more cared for here than elsewhere. Trade is carried on with Kiakhta, a distance of 165 miles.

As regards the sort of goods sold in these Chinese settlements in North Mongolia, I made a brief list of them in 1908, and I imagine such a list holds good to-day: Russian goods of all kinds (especially household utensils), silks, Chinese and Mongol boots and shoes, Chinese hats and caps, Chinese robes, snuff-bottles (a very necessary article of daily use in Mongolia, as the exchange of snuff-bottle is the Mongol form of salutation), cotton cloth, instruments for temple use, sheepskins, chop-sticks and cheap Japanese goods, especially looking-glasses, towels, beads and chains, photos of Japanese singing girls, knives, scent, soap, snuff, tobacco (Chinese *not* foreign), Mongol kettles, rugs of gaudy colours. The amount of cheap gaudy Japanese articles struck me in 1908 as enormous, and they attracted both Chinese and Mongol alike. Raisins, dried apricots, eggs, flour, rice, millet, salt and vegetables were the chief foodstuffs on sale—all brought from China, the stock being renewed regularly by caravan.

The products of Mongolia are wool, hair, skins and animals (especially sheep and ponies), and these are bartered for the ordinary commodities of life. There was in 1908 no metal currency, the chief item of barter being the teabrick; in one district I found long strips of coloured rags used for barter. Both Chinese cash and lump silver are taken in the settlements, but much of the silver which comes in is used by the women for personal adornment, or by the men for ornamenting their saddles. Russian money was also used in Urga, but I understand that it has given way now to the Chinese dollar. I will refrain from saying anything about the activities of the Chinese or Russo-Chinese banks, as I have no up-to date information on the subject. I imagine, however, that the Mongol nature has not changed, and that he is still a happy-go-lucky spendthrift, ready to throw away his property in exchange for anything which glitters or which takes his momentary fancy. He will thus always be in debt to someone. The Chinese traders established at certain camps in the desert act also as money-lenders and, in default of payment, frequently receive some of the debtor's cattle, which is then convoyed to China and sold at a considerable profit to the trader. I have seen this adversely commented upon in certain modern books of travel. I cannot understand why; it seems a perfectly fair businesslike transaction.

From Urga we retraced our steps to Saire Ussu, and turned north-west to Uliassutai, a month's journey by camel, and crossed the Onghin, Tatz, Tui, Ut, Baiderik and Djak streams, all of which flow from the Khangai to be lost in the desert. The valleys are full of rich grass, on which thousands of beasts feed. Well watered and sheltered, these valleys support only a small population as yet, and would make excellent farm land. At this stage the weather is worth mentioning, for we had been delayed at Urga by the excessive rains, and these had pursued us as far as Saire Ussu. Nothing is done, however, for the conservation of the rainfall, nor of the waters of the above-quoted streams with a view to irrigate the districts.

After climbing out of the Djak valley we crossed the ridge which parts the waters of these streams from those which flow northwards to the lakes in North-West Mongolia, and descended into the valley of the Chobolgol, a headwater of the Jabkon. Thence we proceeded into the valley of the Buyuntugol, and at Hochertu camp came across the first Russian trader residing in the desert. This is an indication of the extent to which Russians had penetrated into the country—not that it appeared to be to the detriment of the Mongols, for the Russians brought plenty of goods to barter for the wool, etc., and one of the features of the district was the number of well-to-do Mongols riding about in long crimson cloaks. One traveller writes of the "red-coated" Mongols, but this was the first instance I met of Mongols wearing red coats, nor did I notice any similarly clad outside the Uliassutai district.

On reaching Uliassutai we crossed the Bogdingol by the Green Dragon bridge.

The town has many points of comparison with Urga, the chief being the abundance of water (which, however, is bad for drinking on account of the wool-washing done in the stream) and the all-pervading squalor. It consists of a number of houses—of wood or of mud or of both—with large yards attached to them, each being surrounded by a high palisade of poles. The streets and lanes thus have a singularly uninteresting character, and after rains they become long pools. In the only important street the Chinese and Russian shops were to be found side by side, for the time had passed when, according to Ney Elias, the Russian traders were herded together in a joss house outside the town. But there was a forlorn appearance about the street which testified to the absolute stagnation of trade. The Russian traders numbered seven or eight (as Ney Elias records three in 1872 the increase has not been rapid), and shared in the general depression. A few Chinese merchants were engaged in the wool trade, but this and the hair trade were practically monopolised by the Russian traders who had erected sheds for cleaning and drying these commodities in all the neighbouring valleys as well as in that of the Bogdingol.

The life of Uliassutai was thus gradually being squeezed from the Chinese. Ney Elias's description of Uliassutai in 1872 holds good to this day, and the settlers have still made no further attempt at cultivation than that of cabbages and turnips for local consumption, while, as nothing has been done to reafforestate the hills, the supply of wood, which in 1872 was "scanty and hard to find," must to-day be scantier still.

As at Urga, so at Uliassutai there was a Russian Consul. There was none at Kobdo nor Sharasumé.

The journey from Uliassutai to Kobdo took us eight days. In a country such as Mongolia where landmarks are scarce, it may be interesting to note that three miles before reaching Kobdo there is an Obo or cairn of special sanctity.

Ney Elias noted in 1872 the scarcity of wood in this district also, and this scarcity is so great to-day that small brushwood has to be brought from a very considerable distance for the needs of the settlement. There has been no change in the appearance of the colony during all these years. There are the usual two mud-built towns, the official so-called fortress, and the open trading quarter; but the streets of the latter are wide and clean—quite unlike those of Urga or Uliassutai—and rows of fine trees grow on either side of the main thoroughfare.

Unlike Urga and Uliassutai, Kobdo is rich in vegetables—potatoes, beans, carrots, turnips, melons and cucumbers being grown plentifully. Nearly every house had its own small garden, and each was well watered by a small irrigation canal from the river.

Preparations had now to be made for crossing the Altaishan to Sharasumé, and the Amban kindly detailed an officer off to escort me thither. He also furnished a special passport in Mongol and Hassack. Our movements were slightly hampered by a convoy of German guns which were being forwarded to Sharasumé.

We left Kobdo by the Suok road (Suok is the frontier station at which commerce enters and leaves Mongolia in this region), but two days later turned westwards over the

mountains. I will not weary you with a detailed geographical description of the country we now traversed. We were always climbing passes to drop into depressions containing lakes of varying size and fording icy-cold streams, for it was the first week in September and the passage over the Altais is closed by snow from September to April, the scanty population migrating for this period to the foot of the western side of the range. At Daunnoor we reached a narrow belt of fir and then crossed the bleak main chain of the Altais by the Ermektudaba pass and were in the headwaters of the Kran (or Kilingho), itself a headwater of the mighty Irtish. Dropping rapidly through blinding snow and in bitter cold, we entered another zone of thick fir forest, followed by woods of willow, birch and poplar, with a dense mass of low scrub, and wound our way down the western face of the Altais to Sharasumé, and to summer again.

Sharasumé, Altaishan or Chenghwassu, is the new colony to which I have already referred. In 1908 there were only ten Chinese shops, all branches of Peking and Tientsin establishments. They sold articles of clothing, snuff-bottles, and the necessaries of life, renewing stock three times a year *viâ* Guchen by camel caravan. The entire population of the settlement was not more than 1,200, of whom 1,000 were "soldiers." The traders found existence difficult. The Amban, a most enlightened and cultivated official, of whom I still have the kindliest recollections, complained bitterly that there was no telegraph, and he had asked for permission to connect his colony with Manas by telegraph; every matter had to be sent to Chuguchak by horseman to be telegraphed to Peking. Chuguchak is a month to the west by camel caravan. He spoke of the necessity, too, of linking up the colony with the nearest Russian frontier station, Zaisansky Post, whence are brought light bamboo furniture, muslin curtains, window glass, and other amenities of life at Sharasumé. He said there was an abundance of coal and gold in the mountains and that he knew where they were. He added that the object of his Government was to establish order where chaos had reigned supreme, to civilise the Mongols and Turkis (he had just issued an order that the Mongols must bury their dead instead of throwing them out to the dogs in the desert), and to exploit the mineral wealth. There is also an abundance of ginseng in the district.

I will not trouble you with an account of the remainder of the journey to Buluntogoi, thence to Chuguchak past the Tourgout prince's fixed residence, and on to Kuldja, beyond to note that Buluntogoi is merely a geographical expression and is not a large settlement such as the maps appear to indicate; that the Tourgout prince is the descendant of that Mongol tribe which, emulating the migration of the Israelites from Egypt, quitted the Volga *en masse* in 1771 for their present district (of 70,000 families only a portion survived the journey), and that Chuguchak is a busy commercial place close to the Russian frontier and its trade is chiefly with Russia, as is also that of Kuldja, the approach to which, over the Borokhoro range, by the picturesque but narrow Talki Gorge, is blocked by deep snow in winter, as I found to my suffering in October 1908.

And there I will stop, merely adding that unless and until rapid means of communication across the desert exist the trend of the trade of the north districts must inevitably be towards Siberia. It will be a long time before the Mongols are consumers to any extent. They lack everything, it is true, but their needs are few and still primitive. The resources of what is called Mongolia are, however, an unknown quantity, and the country, especially in the north could bear a much larger population and more stock could be raised. The problem is, who will develop it, for the Mongols themselves are incapable of doing so, who will tap the mineral resources, construct irrigation works, and restore Mongolia to that wealthy condition which she seems to have enjoyed in the days of the great Khans.

In view, however, of the ties which have knit China and Mongolia for so many centuries, and of the necessity for filling a political vacuum caused on this frontier of the late Russian Empire (as on others, *e.g.* Persia), there can be, to my mind, no doubt as to the desirability of China resuming that position from which she was ousted by unworthy intrigues. Whether she will be able to retain it will depend on how she tackles the above-mentioned problems.

DISCUSSION.

MR. JOHN BADDELEY said he had not been in Mongolia himself but had only touched the borders of it, so that he could not criticise the paper from any local knowledge. Sometimes, however, a traveller failed to look about him to any great distance on either side, and in any case there were certain points he would like to mention lest those among the audience who had not made a special study of Mongolia and Mongolian history should carry away with them, possibly, some very

erroneous impressions. In the first place in regard to the statement that there was no sand in the Gobi he would point out that while "Gobi" was a Mongol word meaning "desert" the Chinese term for the Gobi was *Shamo*, meaning "sand-desert"; and on various maps, including that of Mr. Ney Elias—one of our greatest Asian travellers and only not more famous because of his own excessive modesty—the word "Gobi" was written right across from the Takla-Makan, or at least from Lob-nor to the Great Khingan, a stretch of from thirty to forty degrees of longitude. Now, if we accepted that as correct we should find that the Gobi contained thousands upon thousands of square miles of sand. On the other hand it was true that on the route followed by the author between Kalgan and Urga there was very little sand. The second point he wished to mention was that the description given in the paper referred to one section of the Mongols only, that is, to the Khalkhas or Northern Mongols, who constituted perhaps a fourth or even a fifth of the whole race. According to the last edition of the *Encyclopædia Britannica* the population of Mongolia was about 5,000,000. But he would take, preferably, the most recent available Russian statistics, those, namely, of 1914, which put the population at between 2,500,000 and 3,000,000 only. Of these the Khalkhas accounted for some 700,000; nearly all the rest dwelt south of the Gobi, the vast majority constituting the celebrated forty-nine banners of the Inner Mongols, whose territories extended along the Great Wall from the Liao River to the Hoang-ho. A traveller proceeding from Kalgan to Urga might see very little of them, for they are all nomads; but they none the less existed and must be taken into account. Besides the Northern Mongols known to the author and these banner-men of Inner Mongolia, there were the Western Mongols or Kalmuks, and this brought him to his third point. As mentioned by the author, the Mongols were turned out of China in 1368 by the Mings, but the author seemed to think that they had played no great historical part after that down to the present day. Now this was not the case. To take but one salient episode in each century. In 1449 a Kalmuk chief, Esen, ruled outside the Great Wall from one end to the other—a distance of some 1,200 miles. Next year, 1459, the Ming Emperor of China, *In-tsong*, came out from Kalgan and fought a battle with Esen, who defeated and took him prisoner. In the sixteenth century the Kalmuks fell back into the second rank, but we find the Eastern Mongols under Altan or Yenta, the powerful chief of the Tumeds, whose capital was the author's *Kwei-hwa-cheng*, not only attacking China in force and raiding whole provinces year after year, but actually besieging Peking. The Portuguese adventurer, Ferdinand Mendez Pinto, whose name the English dramatist Congreve used as a synonym of liar, but who, like most travellers, sometimes told the truth, relates how, as a prisoner of the "Tartars," he was present at this siege in the year 1544, and both siege and date are fully confirmed by the Chinese annals. In the seventeenth century the Manchus appeared on the scene, but before they could take China they had to make terms with, or get rid of, the Mongols. Accordingly they made friends with some, fought and conquered others, and in 1664 took Peking. But even then the Eastern and Northern Mongols were powerful enough to require very careful watching. Finally, early in the eighteenth century, the Kalmuks reached the climax of their power. They had driven their hated kinsmen, the Khalkhas, into final submission to China. They had taken Tashkent and Turkestan (town) from the Kirghiz-Kazaks; they had conquered Chinese Turkestan with all its cities from Yarkand and Kashgar to Turfan and even Hami; they received tribute from the remote Mussulman Saricolis close on the Hindu Kush; and in 1717 they invaded Tibet, stormed Lhassa, and, for a brief period, ruled it. They fought Kang-hi, Yung-chen and Kien-lung, and it was only in 1757 that the latter, after twenty years' strife, finally vanquished and practically annihilated the royal race of the Kalmuks, known as the Sungars or Eleuts. In conclusion, Mr. Baddeley paid a tribute to the paper as one of much interest and extremely well illustrated. He had listened to it with great pleasure.

Mr. Byron Brenan, C.M.G., said that, unlike the author, he had never had the advantage of travelling in Mongolia, but when he was living in North China parts of Mongolia occasionally came to see him. Sometimes on a very fine day in the winter a yellow cloud would be seen on the horizon; then in a short time a breeze would arise which turned into a howling gale, and for three days the air would be thick with dust from the Gobi Desert. At the end of that time the houses and gardens would be covered with at least one-eighth of an inch of Mongolia. In that way, therefore, he had had some acquaintance with the country. Another means of knowing something about Mongolia was that every winter caravans of Mongols came down to trade in Peking, and shortly before the new year strings of camels laden with goods of all kinds, principally frozen food of various descriptions, came down to Peking, and the goods were sold to the people in exchange for ornaments. He did not think that if at any time the Mongols were left to themselves there would be very much chance of trade development. They were easily satisfied, had very few wants and were not at all enterprising. One had only to go back about seven hundred years to the days of Genghiz Khan to see how very much the people had deteriorated. There were opportunities in Mongolia for adventurous people, and those who went there would probably be the Chinese, for wherever there was a chance of carrying on trade, there the Chinese would go. At the present time the great difficulty was finance—the Chinese would bring up goods to sell to the Mongols, and the Mongols would have nothing to give in exchange. The only thing to do was to make contracts far ahead

for cattle, sheep, ponies, and especially wool, but the wool, of course, could only be furnished at a certain time of the year. To give an instance of the difficulties of exchange, he might mention that a good many years ago a very fine Russian circus was coming across to China, and as it had to go through Mongolia its enterprising manager thought he would partly pay his way by giving entertainments in that country. The only kind of currency with which the people could pay for their seats was the dried dung of the camel, and the day after the performance the manager sold the whole heap or exchanged it for something a little more manageable, and repeated the operation at the next stage. The great need of the country was transport facilities, everything being carried by means of camels. At present the railway went from Peking through mountain passes to a place called Kalgan, and he thought it now reached as far as Kweihuacheng. It was intended to carry it on as far as Kiakhta and to connect it with the Trans-Siberian Railway, but the late war, the revolution in China, and all the recent trouble in Russia, had put a stop to those developments. As an instance of what traders suffered from want of transport facilities, he might mention that one of the principal products of Mongolia, wool, was brought to the port of Tientsin, near Peking, and was sent to America to be made up into coarse cloth or carpets. That wool was brought on camel-back a journey of perhaps thirty or forty days, and on the way down the men in charge of the camels would steal some of it, and, having given a receipt for a certain weight, they kept that weight up by sprinkling water over the wool and then scattering sand all over it, with the result that when the wool was passed through cleaning machines in Tientsin, about ten or twenty per cent. of the weight was found to be composed of sand from the desert, on which freight had been paid at the rate of something like £5 a ton to bring it to Tientsin and which necessitated further expense in the cleaning process before the wool could be packed. A good deal could be done to improve the articles which were used as barter in carrying on trade. Many years ago a rich Chinese merchant retired on his fortune to a farm near Peking, and he imported fruit trees, the best grain, and also good cattle. Amongst the animals he brought to his farm were some very fine merino rams which he obtained from California, and finding that his farm did not suit them he sent them into Mongolia. The wool from Mongolia was sent to America and landed at San Francisco, where the American Customs House authorities imposed a duty according to the grade of the wool, which they divided into three classes—the very coarse, the medium, and the best. After the merino rams had been in Mongolia about three years, the Customs House authorities at San Francisco wrote to the American Consul in Tientsin asking him to make inquiries as to why it was that the wool was so very much better than it had been before and stating that it had been transferred from the low to the medium grade. That was entirely due to the few rams that had been sent to Mongolia. The Mongols themselves could not be expected to do that kind of thing, and certainly the Chinese would not, because they were not going to pay £500 for a good ram to be sent to Mongolia for the benefit of the world at large. The Chinese Government could do it, but it was the very last thing it would think of doing. No one could tell what the future of Mongolia was going to be. When it was like a no-man's-land between Russia and China the policy of Russia was to prevent its becoming strong or populated by Chinese, because Russia wanted it as a buffer State and perhaps looked forward to taking it for herself in the distant future. The Chinese encouraged their people to settle in the country as a buffer against Russian aggression. Both Russia and China were *hors de combat* at the present moment, so it was difficult to say what would happen to Mongolia. If there was an opening for trade there the Japanese would not miss the opportunity; they were very strong in Manchuria, which adjoined Mongolia, and they could live in a way in which Europeans could not, as far as expense was concerned, and would discover openings where nobody else would think it possible to embark in trade.

The Chairman (Brigadier-General Sir Percy Sykes, K.C.I.E., C.B., C.M.G.), in proposing a vote of thanks to the author for his interesting paper, said that Mongolia appealed to some people a great deal as the land of Prester John. It was mentioned by the monks Carpini and Rubruquis and also by the great traveller Marco Polo, and, as the author had said, there seemed to have been very little change in the country since that time. The author had not said much about the yaks. His own experience of them was that they were very unpleasant animals, and had a strong dislike for Europeans in the parts of the world where he had ridden them. They had a very curious habit of grunting like pigs, and that is why they were called the "grunting ox." Mr. Baddeley had mentioned the value of the work done by the late Mr. Ney Elias, and personally he thought that explorer's work was becoming more and more appreciated. He agreed with Mr. Baddeley that Mr. Ney Elias had suffered very much through his own modesty, as he could never be persuaded to talk about what he had done. One reference of very great interest made by the author was to the Tourgouts, who were expelled at the beginning of the eighteenth century by the Zungars and journeyed an enormous distance to the Volga. About sixty or seventy years later they found that the Russians were beginning to get a grip on them so they decided to trek back again. That journey had been immortalised by De Quincey in his book, "The Revolt of the Tartars." Another point of interest mentioned by the author was that of communications. Nothing had been more burned into him during his thirty years in the East than the

value of communications. Without modern means of transport there could be no progress. Mines, for instance, that would pay with modern means of transport had not the slightest chance of paying if everything had to be carried on camels. When the Chinese wanted to go from China to Kashgar, in Chinese Turkestan, they went almost round the world in order to obtain good means of communication. First they went by sea round by Singapore and Ceylon and up to Aden, and then to Constantinople, Batum, and Baku. Then they travelled up the Central Asian Railway to Andijan and went by carriage to Osh, whence it was a twelve days' journey to Kashgar. They said it was not only three times as quick to go by that route instead of across land from China to Kashgar, but the cost was only about a quarter as much. The time occupied by the land route would be at least six or eight months. He did not quite agree with the author about the wealth of Mongolia in former days, because he thought that wealth was largely artificial. As the author said, the Mongols ruled as far as the Dnieper, and Matthew Paris mentioned in his chronicles that, in 1238, the Swedish fishermen dared not come to Yarmouth for the herring fishery on account of their fear of the Mongols. At any rate up till the war, prayers were said in the churches in Galicia and other parts of Eastern Europe for deliverance from the Mongols. That showed that the Mongols had an enormous empire. They took everything they could from the countries they conquered and then had to keep on sending presents back to headquarters at Mongolia, but the Mongols did not develop their country in consequence of that. They had probably become very lazy and ceased to be wealth producers, and so when the tide turned and the Mongols went under again, they very soon lost all the wealth that had been poured into their country during the period when they were practically masters of the known world. The geographical formation of Western Europe was probably what prevented the Mongols from completely overwhelming the very weak civilisation that then existed there, and that in turn was mainly owing to the rainfall of Western Europe, which made the stony valleys that were so unlike the country the Mongols were accustomed to, and that was so unsuitable for cavalry. He did not agree with the author that the tent was preferable to the Mongol yourt; personally he much preferred the latter, especially in cold and windy weather. He would like to ask the author what was the name of the trees at Kobdo—an avenue of which had been shown in one of the slides. The question of reafforestation was one that affected rainless countries enormously. Grazing, especially of goats, in most parts of Asia prevented any trees growing, and reafforestation was only possible in countries where there was a strong organised Government, such as in India, where the Government had enclosed huge areas round Quetta and was gradually reafforesting them. He would also like to ask the author whether he obtained any sport in Mongolia.

The Author, in replying to the discussion, said he ought to have made it clear that his paper did not deal with the whole of Mongolia, but only with that part through which he had travelled. He could assure the Chairman that in the valley of the Yellow River from Ninghsiafu to Kweihuacheng and just across the Ordos one could obtain the most magnificent pheasant shooting in the world; every bit of shrub and bush all along the valley contained one or two birds. In the Ordos there was also the antelope, and in the northern part of Mongolia, especially in the valley of the Jabkon, between Kobdo and Uliassutai, there were duck and geese, and, he had been informed, wild swans. With reference to the remarks made by Mr. Brenan about the probable influx of Japanese traders into Mongolia, he thought that was a question that required very careful attention, because where trade went the flag might also follow, and if Mongolia was flooded with Japanese trade political influence might succeed the commercial influence. He regretted that he did not know the name of the trees at Kobdo which he had shown on the slide. He agreed with the Chairman that the Mongols never had been wealth-producers. According to ancient historians they were very well-to-do people, but he agreed that their wealth came from outside the country and might be described as loot. When their power dwindled and they lost their political influence, they naturally lost their jewels and other forms of wealth that they had, and sank into a position of poverty, in which they still remain. With regard to the yourt, he agreed with the Chairman that it might be the most comfortable form of dwelling when leading a caravan life, especially in the winter, but when one was travelling, for instance, over the bleak Ordos district and began to look for a night's shelter, and eventually came across a very wretched little yourt, one acquired a distaste for them which was rather apt to colour any remarks one made about them. Personally, he would very much like to have a yourt in England and set it up somewhere in the country—in fact, it might tend to ease the housing problem if introduced into England.

On the motion of the Chairman, a hearty vote of thanks was accorded to the author for his interesting paper, and the meeting terminated.

OLIVE-OIL INDUSTRY IN SPAIN.

Of all olive-growing lands Spain is the most important in the total yield of oil, and is by nature one of those best fitted to fill its own large demands and furnish an increasing supply for export. Italy, the second olive-oil producing country in Europe, has an area planted with olives about a third greater than Spain has, but its yield in normal years is smaller. The French area under cultivation is confined to the Mediterranean coast, and is reported to be decreasing, since greater profits are obtainable from viticulture.

The range of the olive tree in the European-North African region is, roughly, from 46° to 18° north latitude. North of 44° the yield is irregular and generally light. Though the tree flourishes south of 18° the fruit is not of commercial value. Between these limits the olive will thrive wherever a warm, dry climate and moderate rains are found.

All of Spain, lying as the kingdom does between 36° and 44° north latitude, falls in the olive belt; but the region northwest of a line drawn from the French border on the Bay of Biscay to Madrid, and thence west to the Portuguese border, contributes practically nothing to the total. In 1917 and 1918 the following provinces of this region are not reported as having raised any olives: Valladolid, Burgos, Segovia, Soria, Palencia, Leon, Corunna, Guipuzcoa, Vizcaya, Oviedo, and Pontevedra. In all the other provinces olive products are a staple article of commerce. As a rule, the yield is heavier in the provinces of the east and south coasts. The province of Lerida, in Catalonia, is the most important producing centre in the north. Southwest of Madrid, the provinces of Toledo, Caceres, and Badajos have a heavy yield.

By far the most productive region is found in the valley of the Guadalquiver, including the provinces of Jaen, Cordova, and Seville. It is from this district that the heaviest exports of olive products occur. The western portion of this valley, with Seville as a centre, produces the finest table olives as well as large amounts of oil. The eastern section raises olives used almost exclusively for the making of oil. The centre of activity here is in the province of Jaen, which promises to become the premier oil-producing district of the kingdom, if not of the world.

Owing to the high prices received for olive oil in recent years extensive new plantings are being made in all parts of Spain. The total area of land planted with olive trees in the kingdom is estimated in statistics for 1918-19 at 3,851,288 acres. Of the total fruit reported as produced in 1918, 96·6 per cent. was destined for the manufacture of oil.

The amounts of olive oil produced and the chief regions contributing to the total are shown in the table below. The figures are in metric tons, and only those regions are included which, in one or more of the years cited, yielded 10,000 tons or more. The total given is for all the provinces of Spain, and therefore includes other regions in addition to those mentioned in the table.

In an industry so widely diffused as olive-raising in Spain, there are, of course, great contrasts in the conditions under which production occurs. A large part of the agricultural population of the kingdom is engaged in growing olives. In the north a majority of olive producers are owners or cultivators of small holdings upon which olive-raising is only one of a number of sources of income. In the south the orchards reflect the general land-holding conditions; the plantations are larger, the connection of the actual tiller of the soil with the active management of production is less intimate, and specialisation in olives as a source of income is greater.

Cultivation of land between the trees is generally recognised as advantageous. The best opinion is that the ground should be stirred to a depth of 20 to 22 centimetres. Orchards which have been uncultivated before should at first be given shallow ploughing, the depth being gradually increased in succeeding seasons. In this way the roots will by degrees adjust themselves to new conditions, and the loss in the yield which would result from ploughing at once to the depth indicated is avoided. The advantages of cultivation are the avoidance of reduction in fertility and moisture by the vegetation which would otherwise be produced; the increased porosity of the soil, enabling it to hold the winter rains; the loosening of the land so that the roots can grow more freely; and the lessening of surface evaporation. The conservation of moisture is of the utmost importance in the dry regions whose lands are devoted to olive production.

Immediately after the harvest the orchards should be twice thoroughly cross-cultivated to a maximum depth of 20 centimetres, in order to put the land in the best condition to store up the late autumn and winter rains. In the following April or May another stirring is necessary to keep down the spring weeds, the land nearest the trees which cannot be reached by other means being worked up with spades and hoes. In the hot summer months further superficial cultivation is necessary to keep down the weeds and to maintain a dust blanket to impede evaporation.

As in many other lines of industry in Spain, it is possible to find sharp contrasts in the methods of production of olive oil. The most improved appliances may be in use but a few miles from places where the processes employed in almost

a Estremadura only. *b* Aragon only.

prehistoric times persist. In the province of Toledo, for example, the so-called molinos de viga (bean mills), made of tree trunks, are still much used. Compared with modern hydraulic or electric presses these extract, of course, a much smaller portion of the oil content. The machinery used in oil extraction throughout the Peninsula is still comparatively simple, and, except for pistons for hydraulic presses and a few other parts, has been a product of national industry. Almost all the machines are made in Barcelona.

The pressing is usually carried on in small establishments. Oil olives do not appear in large quantities in the open market. A few mills have been established near Cordova and at Mallagon and Tudela in the province of Saragossa. These mills purchase the green olives from the producers and undertake the manufacture of oil from the pressing to its final packing for export. These establishments are exceptions, and even the greater part of their product is, as a rule, made from oil purchased from smaller operators. The usual practice is for the producer to press the oil from his own olives. A few extract oil for their neighbours also. It is then sold to a commission man or direct to the refiner.

According to a report by the United States Commercial Attaché at Madrid, from which the foregoing particulars have been taken, one of the first requisites for high-grade, first-pressing oil is that the fruit be in proper condition, unbruised, and pressed within a very short time after it is picked, preferably the same day it is gathered. Upon this depends the grade of the oil produced, to a much greater extent than upon the character of the machinery used. A large part of the oil-olive harvest is gathered a considerable time before the oil can be extracted and is allowed to deteriorate by fermentation. The result is that the first-pressing oil marketed by large numbers of growers has a much higher acidity than is permissible for the finer grades of oil for export. It is estimated that an amount not greater than 20 or 25 per cent. of the total olive oil produced in Spain can be graded as "aceite fino." One of the reasons alleged for the superiority of oil from certain regions, like that from Tortosa, is that there the number of mills is more nearly sufficient to allow the prompt pressing of the fruit. A very fine grade of olive oil is produced in the northern region near Alcaniz, in the province of Teruel. In Andalusia the region around Velez is famous for the quality of the product.

After the first pressing hot water is added to the pulp, and it is then pressed again, the oil thus extracted being of much lower grade and not entering export trade in unmodified form. There are usually but two pressings, though a third is occasionally given the pulp, the same process being followed as in the second.

Until about twenty-five years ago no important part of the pulp was used in further industrial processes. The pulp was used locally as fertiliser or fuel, or fed to live-stock—especially hogs—as is still the case in many parts of Portugal. Since that time the so-called sulphur-oil industry has developed. The orujo, or pulp left after the above-described pressings, is sold by the producer to the sulphur-oil factories, either directly or through speculators who travel from farm to farm to collect it. These latter not infrequently advance money to the smaller farmers against the orujo which will be produced in the coming crop. The oil content of the residue was formerly greater than at present because of the less effective extracting machines then used. It now averages not over 10 per cent. Nevertheless, the money value of the orujo has risen in recent years, and what was formerly considered almost valueless now contributes an important percentage to the olive-grower's income.

The aceite orujo, or sulphur oil, which is extracted from the pulp, is the basis of the manufacture of a large part of the soap used in Spain, for which it was formerly necessary to use the lower grades of olive oil. Sulphur oil is also exported in large quantities for soap making and other industrial uses.

After the extraction of the aceite de orujo there still remains a brown flaky, charcoal-like substance called picon de orujo, which burns with no smoke, and is used locally in braziers in the winter months to warm dwellings, and to supplement the fuel supply of the soap factories where it is produced. It is also in demand in brick factories because of the high heat which it generates.

The best methods of refining olive oil are found in Andalusia, especially in the Malaga district. Even here it is only recently that modern scientific apparatus has been introduced. Southern oils as they come from the mills are said not to compare favourably with those from Aragon; but, with the present methods of manufacture, the product of Andalusia, when it is ready for export, is claimed to be comparable with the best oils produced in the Peninsula.

The edible oil purchased from the producers by the refiners (who are regularly also exporters) is divided into grades to fix the rate of payment. This is determined chiefly on the basis of the acid content. Oil with less than one-half of 1 per cent. acidity is paid for at the highest rate. Lampant oils must not have an acid content over 3 per cent. Up to that standard the oils are regarded in the local market as edible. The poorer oils run as high as 10 per cent. acid, but these are suitable only for commercial uses. The refineries store the purchased oil in large tanks, often situated under the refinery building, from which it is pumped as required. Formerly the product of the first pressing included all the high-grade oil produced, but with the development of refining processes this has ceased to be the case. The second-pressing oils and poorer grades of the first pressing, when put through the rectification processes, can be brought out light-coloured, with almost no taste and free from acid.

They can then be mixed with the first-pressing oils, which, especially in Andalusia, are too highly fruited for some markets.

In this way it is made possible to produce exactly the blend demanded. The refined oils made from the lower grades thus become a stabilising factor which enables the refiner to keep the brands he establishes of uniform character. The only appreciable difference between the first pressing and the refined oils is in the flavour and the colour. Chemically they are practically identical. As a rule only the fine-grade oils and those grades mixed with refined oil are sold in the United States, where a light-coloured product with little taste is in demand. Fine and medium oils are sold in northern Europe. The medium grade finds a large market also in Argentina and other South American markets. Generally, South America demands oils of high flavour. The corriente grade is sold in Spain and in Cuba.

Among the most important refineries are three in Malaga capable of handling a total of about eighty tons daily. Another will shortly be in operation, and one is under construction at Bobadilla. In Cordoba there is one large olive-oil refinery, and others at Montoro and Mucena in the same region.

INTER-ANDEAN REGION OF ECUADOR.

Ecuador has been divided by nature into three distinct regions—the coast, the Montana, and the Oriente, or eastern slope of the Andes—embracing the headwaters of many of the most important tributaries of the Amazon. Of these three regions, the coast is probably the most important commercially. Its metropolis, and practically the only important port of Ecuador, is Guayaquil. Much of the coast region is inundated during the wet season, which commences usually in December. The Oriente, though perhaps richer in possibilities than any or all of the other portions of the country, is at present wholly undeveloped, and accessible only to expeditions specially equipped for exploration of the wilderness. There remains the Montana, or Andean, region, regarding which the following particulars have been furnished by Mr. H. L. Smith, Special Assistant, State Department, Guayaquil.

The inter-Andean region of Ecuador, except a small portion south of Cuenca, is something less than 250 miles long, and is from 8,000 to 12,000 feet above the sea, from which it is separated by the very difficult western Cordillera, pierced here and there, but not often, by gorges. These gorges are, in general, so steep, with such precipitous walls and so rugged as to be impracticable as outlets for railways, cart roads, or even trails. With the exception of one railway of recent construction, there are nothing but trails as means of access from the coast to the valley-plateau.

These trails, extremely primitive, difficult, and dangerous, but called "caminos," or roads by the inhabitants, wind over the surface of the mountains to passes from 12,000 to 14,000 feet high, from which they descend to the central valley. Over these trails, burros, mules, and, to a limited extent, small horses, can carry 200 pounds or a little more of freight carefully balanced on their backs. Until the advent of the one railway from Guayaquil to Quito they constituted the sole means of access to the world, and still so constitute it to all portions of the valley not accessible to the railway. The valley closes both to north and south within the limits of Ecuador in nests of mountains that for all practical commercial purposes preclude entrance from either Peru or Colombia. On the eastern side of the valley it seems that the slopes of the eastern range are gentler, the gorges less precipitous, and that entrance from that side would be considerably easier. But this is of no practical importance at present.

As far as is known, this region is without valuable mineral deposits, though an inferior grade of coal and what seems to be a good quality of kaolin and marble are found in the southern part of Azogues. It must be borne in mind, however, that the country has been prospected only to the most limited extent, and as it is known that many of the rivers of the Oriente are auriferous, it is possible that the eastern of the two ranges that bound the valley will be found to be gold-bearing when they have been more thoroughly explored.

Generally speaking, the valley is devoid of trees; but the eucalyptus, introduced some forty years or more ago from Australia, seems to thrive here even better than in California, and plantations of it are continually being extended.

The growth of the tree is so rapid that it may be profitably cut every five years, being then worth 5 sucres, about 10*s.* Each one, therefore, produces 2*s.* worth of wood per year, when thus cut, and, as the trees may be planted from 6 to 10 feet apart, the yield each year per acre on the average would vary between £44 and £120. The eucalyptus tree shoots up rapidly from the root when it is cut, so that a plantation lasts indefinitely, differing in this respect from nearly every other useful wood. It is the usual fuel of the country, either dried or converted into charcoal; it is used in the locally made furniture, and for such wood as is used in building construction.

The rainfall of the Montana, even for places of the same altitude, varies more than would be supposed. In general, it is deficient, especially during the verano (summer, or dry, season), from the first of July to about Christmas time. The term invierno (winter) is applied to the wet season, say from 1st January to 1st July. These changes of season are, however, by no means fixed; they vary from year to year and from one part of the region to the other. It will then readily be inferred that much of the country presents a desert aspect, and is characterised by desert vegetation—cactus, agave, yucca, broom—and by drifting sands and scanty herbage. The more elevated regions, say, above 11,500 ft., locally called paramos, are, in general, sufficiently

watered at all times by the clouds and fogs that rest upon their surface. Vegetation is there limited by temperature rather than dryness, and the paramos are covered with clumps of a coarse and wiry grass called paramo grass, which cattle are said to like when it is young.

Agriculture, including the raising of stock, is the industry of the region, and the crops raised are those of the temperate zone. The small grains, maize, potatoes, varieties of beans, and alfalfa are the principal crops, with some fruit of an inferior sort raised near Ambato. Practically all the agricultural work is done by Indians either on small tracts owned by them or on large haciendas.

Agricultural methods are very primitive. About 99 per cent. of the ploughing in Ecuador is nothing more than a shallow stirring of the surface of the soil by a sharpened board with an iron point drawn by a team of oxen and furnished with an iron handle, with which the farmer keeps the plough upright. There is no pretence of turning over the ground; it is simply slightly furrowed. The agricultural lands of this region have never been turned over or even stirred to a depth of more than 4 or 5 inches. Nor have they ever been fertilised. There are no barns or barnyards. There are vast herds of cattle, but the climate makes all shelter superfluous, and they live the year round on pastures which have never been ploughed.

Farming operations consist in the depositing of the seed in the land. The crop is cultivated with mattocks and an instrument like a heavy crowbar flattened at one end into a broad chisel 4 or 5 inches wide. Probably there does not exist in the whole district an instrument for horse or other power cultivation. Of course the crops obtained by this cultivation are small and wholly inadequate.

Irrigation seems to be managed with a fair amount of skill, and in one respect the Andean farmer is unexcelled—the utilisation of hillsides.

Most of the well-watered surface of the valley is devoted to cattle-raising. The cattle are raised on large estates or haciendas consisting frequently of many thousands of acres covering the valley and running far up the mountain slopes. The cattle live in the pasture the year round, and are sold from the pasture without any further fattening or attention. Few of the haciendas possess the amount of stock they are capable of supporting, so that the industry is capable of considerable expansion.

There are few manufactures in the Montana region, the chief being some small potteries and a few textile factories. Apart from these there is a cigar, cigarette and match factory in the Chillo Valley, some 10 or 15 miles from Quito.

Any great development of modern industry or commerce will be dependent upon an improvement of transportation facilities. One railway, with grades running up to 6·5 per cent., the operation of which is seriously interrupted in the rainy season, now connects a portion, not over half, of this valley with the coast. The maximum goods train on this line consists of four trucks.

Within the valley itself there are a few trails, especially in the northern part, that might easily be made feasible for carts. Some of them are so used to a limited extent at the present time. About forty-five years ago a longitudinal road within the valley, with substantial bridges, and wide enough for wheeled traffic from Quito to Riobamba, a distance of about 125 miles, was constructed. This is the sole road professedly for vehicles in the region described. Only the crudest and most perilous trails exist between the valley and the coast.

Obviously a preliminary to any great development of the valley will be better communications, not only between different parts of the valley, but also between the valley and the coast. Accordingly, various schemes for railways have been broached, at least two connecting Quito with different points on the coast, and one extending the existing longitudinal system to Cuenca. The construction of two of these has been begun as a Government undertaking, but is not completed. A third line to pierce the eastern cordillera and connect Ambato with the Oriente has also been started.

NOTES ON BOOKS.

FOREST WOODS AND TREES IN RELATION TO HYGIENE. By Augustine Henry, M.A., F.L.S. London: Constable and Co., Ltd. 18s. net.

This volume forms part of the Chadwick Library, a valuable and gradually growing collection of books springing out of the lectures which are constantly being given under the Chadwick Trust.

Popular ideas as to the effect of trees on sanitation are apt to be vague. Most people have views upon the subject—some, exceedingly strong ones; but probably few could give scientific grounds for the theories which they advance. Dr. Henry, Professor of Forestry at the Royal College of Science, Dublin, has endeavoured to state the case fairly, and he supports his arguments by a mass of well-ordered information. He begins by describing the far-reaching influences of forests and trees on climate, flow of water, soil erosion, shelter from wind, purity of air and water, etc. —all influences directly affecting our health and comfort. He then proceeds to discuss the value of forest districts as sites for sanatoria. Forest air is free from injurious gases, dust, particles, and bacteria, while the soil is hygienically pure. Tubercular patients require open-air treatment, and at the same time should be protected against cold or severe wind, which raises dust and generally increases cough and dyspnœa. Such protection is best afforded by pine trees, which have been recognised since the days of Pliny as having a beneficial effect on people with a tendency to phthisis.

Professor Henry is a staunch believer in the value of trees in towns, where their beauty of

colour and form exercises a powerful if sometimes unconscious effect on the townspeople. He goes into some detail in describing which trees will thrive in city surroundings, and which will not; and he has an interesting chapter on the afforestation of pit mounds, on which unpromising soil some surprisingly good results have been obtained. The greater part of the book is devoted to the question of the afforestation of catchment areas; and here will be found a large quantity of detailed information showing the kinds of trees most suitable for different situations, and particulars of a very large number of such areas scattered throughout the United Kingdom.

GENERAL NOTE.

Glauber's Salt in Siberian Lakes.—The following is an estimate of supplies of precipitated Glauber's salt in some of the Siberian lakes, quoted by the American Department of Commerce from a Vladivostok economic journal: (1) The Great Marmyshansk Lake—144,000,000 pouds (2,592,000 tons of 2,000 lb.) of crystalline salt ($Na_2SO_4 10H_2O$), and 22,000,000 pouds (396,000 short tons) of evaporated Glauber's salt; (2) Little Marmyshansk Lake—25,000,000 pouds (450,000 short tons) of crystalline salt; (3) Lake Tuskal (Minusinsk district)—up to 100,000,000 pouds (1,800,000 short tons) of crystalline salt; (4) Lake Varche (Minusinsk district)—up to 100,000,0 00 pouds of precipitated crystalline salt, and an enormous quantity of Glauber's salt in solution.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday afternoons, at 4.30 p.m.:—

April 14.—Joseph Thorp, "The Fundamental Basis of Good Printing." Sir Herbert Morgan, K.B.E., will preside.

April 21.—Air-Commodore Edward Maitland, C.M.G., D.S.O., A.F.C., "The Commercial Future of Airships." The Marquess of Londonderry, K.G., M.V.O., Under-Secretary of State for Air, will preside.

April 28.—Brigadier-General Charles H. Sherrill, LL.D., "Ancient Stained Glass." The Right Hon. Lord Desborough, K.C.V.O., will preside.

May 5.—Dr. C. E. Kenneth Mees, "A Photographic Research Laboratory." Sir Henry Trueman Wood, Chairman of the Council, will preside.

May 12.—Graily Hewitt, "Rolls of Honour."

May 19.—John Somerville Highfield, M.Inst.C.E., M.I.E.E., "Electrical Osmosis." Alan A. Campbell Swinton, F.R.S., will preside.

Indian Section.

Thursday afternoon, at 4.30 p.m.:—

April 15.—Sir George Cunningham Buchanan, K.C.I.E., M.Inst.C.E., "The Ports of India: their Administration and Development." The Right Hon. E. S. Montagu, M.P., Secretary of State for India, will preside.

Thursday afternoon, at 5 p.m.:—

May 20.—Brigadier-General Lord Montagu of Beaulieu, C.S.I., "Roads and Transport in India."

Monday afternoon, at 4.30 p.m.:—

May 31.—Albert Howard, C.I.E., M.A., A.R.C.S., F.L.S., Imperial Economic Botanist to the Government of India, "The Improvement of Crop Production in India." Sir Robert W. Carlyle, K.C.S.I., C.I.E., will preside.

Date to be hereafter announced:—

Sir Valentine Chirol, "The Enduring Power of Hinduism." (Sir George Birdwood Memorial Lecture.)

Colonial Section.

Friday afternoon, at 4.30 p.m.:—

May 28.—Professor William A. Bone, D.Sc., Ph.D., F.R.S., "Lignite."

Indian and Colonial Sections.

(Joint Meeting.)

Friday afternoon, at 4.30 p.m.:—

June 4.—Professor Sir John Cadman, K.C.M.G., D.Sc., F.G.S., M.Inst.C.E., "The Oil Resources of the British Empire."

Cantor Lectures.

Monday evenings, at 8 p.m.:—

Walter Rosenhain, B.A., D.Sc., F.R.S., Superintendent, Department of Metallurgy and Metallurgical Chemistry, National Physical Laboratory, "Aluminium and its Alloys."

Syllabus.

Lecture I.—April 12.—Production of aluminium—Raw materials—Purification—Reduction process—Purity attainable—Deleterious impurities—Properties of pure aluminium in the cast and rolled state—Uses of pure aluminium—Its advantages and defects.

Lecture II.—April 19.—Aluminium alloys—Combination of strength and lightness—"Specific tenacity"—Alloys with copper, with zinc, and with zinc and copper—Constitution, microstructure,

and physical properties in cast and wrought states —More complex alloys—Containing magnetism—Limitations to the use of magnetism—"Hardening" alloys.

LECTURE III. — APRIL 26. — Special Uses of aluminium alloys—Castings for automobile and aeroplane parts—Castings for aero-engines—Pistons and piston alloys—Properties at high temperatures —Automobile and aero-cylinders — Other engine parts—Structural uses—Rigid airships, aeroplane spars, and wing-coverings—Possible future developments.

ARTHUR THOMAS BOLTON, F.R.I.B.A., F.S.A., Curator, Soane Museum, "The Decoration and Architecture of Robert Adam and Sir John Soane, 1758–1837." Three Lectures.
May 3, 10, 17.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, APRIL 12... ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Dr. W. Rosenhain, "Aluminium and its Alloys." (Lecture I.)

Victoria Institute, Central Hall, Westminster, S.W., 4.30 p.m. Rev. J. E. H. Thomson, "The Pentateuch of the Samaritans: when they got it, and whence."

Royal Institution, Albemarle-street, W., 5 p.m. General Monthly Meeting.

Engineers, Society of, at the Geological Society, Burlington House, W., 5.30 p.m. Professor E. R. Matthews, (a) "Flood Prevention Works at Troon, Ayrshire; (b) The Action of Sea Water on Concrete."

Chemical Industry Society of (London Section), at the Chemical Society, Burlington House, W., 8 p.m. 1. Dr. W. E. Brenchley and Mr. E. H. Richards, "The Fertilising Value of Sewage Sludges." 2. Dr. E. P. Perman, "A New Test for Incorporation." 3. Messrs. T. M. Lowry and L. P. McHatton, "Experiments on Decrepitation."

Geographical Society, Kensington-gore, W., 5 p.m. Colonel Sir Sidney Burrard, "A Brief Review of the Evidence upon which the Theory of Isostasy is based."

British Architects, Royal Institute of, 9, Conduit-street, W., 8 p.m. Mr. J. Begg, "Architecture in India."

TUESDAY, APRIL 13...Electrical Engineers, Institution of (Scottish Centre), 207, Bath-street, Glasgow, 7.30 p.m. Squadron-Leader J. Erskine-Murray, "Wireless Telegraphy."

Royal Institution, Albemarle-street, W., 3 p.m. Major G. W. C. Kaye, "Recent Advances in X-Ray Work." (Lecture I.)

Alpine Club, 23, Savile-row, W., 8.30 p.m.

Civil Engineers, Institution of, Great George-street, S.W., 5.30 p.m. 1. Lieutenant-Colonel J. K. Robertson, "Richborough Military Transportation Depot." 2. Major F. O. Stanford, "The War Department Cross-Channel Train-Ferry."

British Decorators, Institute of, Painters' Hall, Little Trinity-lane, E.C., 3 p.m. Annual General Meeting.

Photographic Society, 35, Russell-square, W.C., 7 p.m. 1. Mr. A. C. Banfield, "Prisms." 2. Mr. A. J. Munro, "Machinery used in the Manufacture of Photographic Plates."

Anthropological Institute, 50, Great Russell-street, W.C., 8.15 p.m. Mr. A. O. Neville, "The Western Australian Aborigines, their Treatment and Care."

Zoological Society, Regent's-park, N.W., 5.30 p.m. 1. Mr. A. Willey, "An Apodous *Amia calva*." 2. Messrs. H. A. Baylis and C. Lane, "A Revision of the Nematode Family *Gnathostomidæ*." 3. Dr. W. J. Dakin, "The Onychophora of Western Australia." 4. Mr. A. M. Altson, "The Life-history and Habits of Two Parasites of the Blow-fly."

Colonial Institute, Central Hall, Westminster, S.W., 8 p.m. Mr. C. Turnor, "The Organisation of Migration and Settlement within the Empire."

Horticultural Society, Vincent-square, Westminster, S.W., 3 p.m. Dr. A. B. Rendle, "Plants of Interest in the Day's Exhibition."

Chadwick Public Lecture, at the Royal Sanitary Institute, 90, Buckingham Palace-road, S.W., 8 p.m. Sir Daniel Hall, "Gardening and Food Production." (Lecture I.)

WEDNESDAY, APRIL 14 ... ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Mr. J. Thorp, "The Fundamental Basis of Good Printing."

Aeronautical Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Paper by Major-General Sir W. S. Brancker.

Public Analysts, Society of, at the Chemical Society, Burlington House, W., 8 p.m. 1. Mr. A. E. Parkes, "The Turbidity Temperature of Fats, Oils, and Fatty Acids." (Part II.) 2. Dr. G. W. Monier-Williams, "The Interpretation of Milk Records." 3. Messrs. A. F. Joseph and G. A. Freak, "The Loss of Free Ammonia from Drinking Water Samples." 4. Mr. E. Sinkinson, "A Decanting and Filter-Washing Machine."

Automobile Engineers, Institution of, at the Institution of Mechanical Engineers, Storey's-gate, S.W., 8 p.m. Dr. W. H. Hatfield. "The Most Suitable Steels for Automobile Parts."

United Service Institution, Whitehall, S.W., 3 p.m. Lieutenant-Colonel J. Shakespear, "Recent Events on the Assam Frontier."

THURSDAY, APRIL 15...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Indian Section.) Sir George Cunningham, "The Ports of India: their Administration and Development."

Royal Society, Burlington House, W., 4.30 p.m.

Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Linnean Society, Burlington House, W., 5 p.m. 1. Captain F. K. Ward, "Natural History Exploration on the North-East Frontier of Burma." 2. Mr. R. Paulson, Exhibition of Lantern-slides illustrating definite stages in the sporulation and gonidia within the thallus of the lichen *Evernia Prunastri*, Ach.

Child Study Society, at the Royal Sanitary Institute, 90, Buckingham Palace-road, S.W., 6 p.m. Professor W. Ripman, "Spelling Reform."

Chemical Society, Burlington House, W., 8 p.m.

Royal Institution, Albemarle-street, W., 3 p.m. Mr. S. Skinner, "Ebullition and Evaporation." (Lecture I.)

Camera Club, 17 John-street, Adelphi, W.C., 8.30 p.m.

Electrical Engineers, Institution of, Victoria Embankment, W.C., 6 p.m. Dr. C. V. Drysdale, "Modern Marine Problems." (Kelvin Lecture.)

Numismatic Society, 22 Russell-square, W.C., 6 p.m.

Mining and Metallurgy, Institution of, at the Geological Society, Burlington House, W., 5.30 p.m. Presidential Address by Mr. F. Merricks, "The Mineral Production of the Empire."

FRIDAY, APRIL 16...Technical Inspection Association, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 7.30 p.m. Mr. F. R. Wade, "Labour Unrest—its Causes and its Cures."

Royal Institution, Albemarle-street, W., 9 p.m. Dr. J. A. McClelland, "Ions and Nuclei."

Concrete Institute, 296, Vauxhall Bridge-road, S.W., 6 p.m. Mr. E. F. Etchells, "Submission of Plans to Local Authorities."

SATURDAY, APRIL 17...Royal Institution, Albemarle-street, W., 3 p.m. Dr. W. H. Eccles, "The Thermionic Vacuum Tube." (Lecture I.)

Journal of the Royal Society of Arts.

No. 3,517. VOL. LXVIII.

FRIDAY, APRIL 16, 1920.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

MONDAY, APRIL 19th, at 8 p.m. (Cantor Lecture.) WALTER ROSENHAIN, B.A., D.Sc., F.R.S., Superintendent, Department of Metallurgy and Metallurgical Chemistry, National Physical Laboratory, "Aluminium and its Alloys." (Lecture II.)

WEDNESDAY, APRIL 21st, at 4.30 p.m. (Ordinary Meeting.) AIR-COMMODORE EDWARD MAITLAND, C.M.G., D.S.O., A.F.C., "The Commercial Future of Airships." THE MARQUESS OF LONDONDERRY, K.G., M.V.O., Under-Secretary of State for Air, will preside.

Further particulars of the Society's meetings will be found at the end of this number.

CANTOR LECTURE.

On Monday evening, April 12th, DR. WALTER ROSENHAIN, F.R.S., delivered the first lecture of his course on "Aluminium and its Alloys."

The lectures will be published in the *Journal* during the summer recess.

SIXTEENTH ORDINARY MEETING.

WEDNESDAY, APRIL 14th; SIR HERBERT EDWARD MORGAN, K.B.E., in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Abbott, Hon. R. H. S., Bendigo, Victoria, Australia.
Allen, William Thruston, Waipiro Bay, New Zealand.
Buchanan, John, Port Sunlight, Cheshire.
Cross, L. W., London.
Hitchcock, Eldred Frederick, C.B.E., London.
Mansukani, Gulab, M.B., B.S., London.
Marshall, Mrs. M. Katherine, Totley, nr. Sheffield.
Mather, Frederick, B.Sc., Barcelona, Spain.
Matsukata, Goro, Tokyo, Japan.
Savi, Ernest E., London.
Taylor, Captain T. Smithies, Steep Petersfield, Hants.
Wheeler, Major Charles, R.A.S.C., O.B.E., M.I.A.E., Bushey, Herts.
Yorke, Mrs. Constance E., F.R.G.S., Southsea, Hants.

The following candidates were balloted for and duly elected Fellows of the Society:—

Barker, Frederick Walter, London.
Barnsley, Frank Herbert, Dudley.
Burlin, Adolph L., Ph.D., Manchester.
Butterworth, Charles Frederick, Poynton, near Stockport.
Corker, James S., Manchester.
Farrar, George Edward, Richmond, Surrey.
Hoffman, Frederick L., LL.D., Newark, New Jersey, U.S.A.
Lomas, Leslie H., B.Sc., Prestbury, Cheshire.
Oxley, Ernest C. F., Sioux Lookout, Ontario, Canada.

A paper on "The Fundamental Basis of Good Printing" was read by MR. JOSEPH THORP.

The paper and discussion will be published in a subsequent number of the *Journal.*

INDIAN SECTION.

THURSDAY, April 15th; THE RIGHT HON. E. S. MONTAGU, M.P., Secretary of State for India, in the chair. A paper on "The Ports of India: their Administration and Development" was read by SIR GEORGE CUNNINGHAM BUCHANAN, K.C.I.E., M.Inst.C.E.

The paper and discussion will be published in a subsequent number of the *Journal.*

COVERS FOR JOURNALS.

For the convenience of Fellows wishing to bind their volumes of the *Journal*, cloth covers can be supplied, post free, for 2*s.* each, on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

THIRTEENTH ORDINARY MEETING.

WEDNESDAY, MARCH 10th; SIR ROBERT A. HADFIELD, Bt., D.Sc., F.R.S., in the chair.

THE CHAIRMAN, in opening the meeting, referred to the illness of Sir Dugald Clerk, one of the greatest gas engineers in the country, and said he was sure all those present would wish him to send their sincere sympathy to Sir Dugald, and their hope that he would speedily recover. Before calling upon Mr. Thornton to read his paper, he would like to make one or two preliminary remarks. The importance of economising the fuel supplies of this country, and making the best of our means of producing what was called heat, was shown by the latest statistics available. For example, the President of the British Association mentioned at the Bournemouth Meeting that the latest estimate of the total water-power in the British Isles was only 1½ million h.p., and that England only possessed 1 per cent. of that horse-power, and only 2½ per cent. of the total coal in the world. Whilst that was startling, it helped to show that all possible endeavours should be made to save fuel consumption, and to make that consumption of as great efficiency as possible. "Many a mickle makes a muckle," and so in the technical world, by paying attention to the small things, we were able to economise and make the most of what was given to us by Providence. Many propositions had been suggested; for instance, the late Mr. B. H. Thwaite very strongly put forward—and there was some reason in his contention—that power should be developed at the coal mines *in situ*. Why should the coal be hauled from the pits in which it was found and a great deal of money be spent in distributing it, when central power-stations could be provided close alongside the coal, at the bottom of the shaft, and out of the way of hostile aircraft? That seemed a very attractive arrangement, and yet it was thirty years since Mr. Thwaite and others put forward the suggestion, and he was not aware of a single instance where it had been put into practice—at any rate not on a large scale. Sir Charles Parsons suggested boring a hole in the crust of the earth for a depth of ten or twelve miles to obtain the earth's latent heat, but, although there was probably nothing insurmountable in that proposition, it was doubtful whether it would be tested in practice for a long time to come. One might run through a whole gamut of suggestions, many of them containing apparently the germs of important economy, but still nothing was done. If it took this country generations to settle down to such a sensible project as having a Channel tunnel, how long would it take it to consider the excellent suggestion of Sir Charles Parsons? We were ready to waste millions annually in wild-cat schemes, in many cases rejecting the views of the wise men amongst us. In any case, however, we could try to effect economy in present practice, and in that respect he thought Mr. Thornton had done great work, by means of his lectures and the products of his firm, in bringing about many very useful economies. When he (the Chairman) was President of the Society of British Gas Industries, he offered a prize with a view to stimulating interest in that important question, and quite a number of useful theses were submitted, the prize being awarded to Mr. F. W. Epworth, of the Richmond Gas Stove and Meter Company, for a most valuable paper on "The Utilisation of Gaseous Fuel in Commercial Practice." With regard to the question of the value of coal, the exports of coal in January, 1919, and January, 1920, were respectively 2¼ million tons and 3½ million tons, with values of £4,000,000 and £11,500,000 respectively, that being an average price per ton of 34*s*. 8*d*. and 68*s*. 9*d*.—the latter figure brought home to us the great desirability of economising our heat products in every possible shape and form. It was interesting to note that the total production for the present year was estimated at 230,000,000 tons, of which it was estimated that 49,000,000 tons would be for export and bunkers and 181,000,000 tons would be for inland purposes. It was hoped that the miners would do their share in the present reconstruction period and settle down to really useful and hard work. There was one crumb of comfort in regard to the labour situation, namely, that in January only 184,000 days were lost by disputes which began during that month. That was very satisfactory, in view of the fact that in January, 1919, 3,000,000 days were lost in that way. That showed the serious amount of waste that prevailed not only in materials but on the human side, and it was to be hoped that the recent improvement would be maintained.

The paper read was—

GAS IN RELATION TO INCREASED OUTPUT AND NATIONAL ECONOMY.

By H. M. THORNTON, J.P., Assoc.Inst.C.E.

Five years ago I read a paper before your Society detailing the very varied and important uses of coal gas for industrial purposes. This was followed in 1917 by a review of some of the valuable services rendered to the nation by coal gas during the strenuous days of the war. To-day I wish to continue the story, and show the application of gas to peace-time conditions, and particularly the contribution it has to offer to the difficult problem of production which confronts the manufacturer to-day. The use of gas for manifold industrial purposes was not a mere war-time improvisation; and, unlike some of the features of that stressful time, its value has not vanished with the return of peace, and its power has not diminished with the cessation of the demand for munitions of war. Rather

as the outcome of satisfactory experience in many realms of industry, and of confidence built on a foundation of good work rendered at a critical period, its prestige stands higher, its applications are more widely known, its possibilities are more appreciated by manufacturers, and the universality of its service is more generally realised.

In common with other of our important industrial utilities, coal gas for manufacturing processes may be said to have come into its own during the last five years or so. Not that gas was unused for industrial work before 1914, or its value unrecognised. But war conditions gave it an impetus that it might never have received in peace time; and more progress, in its adaptation to manifold processes, was made in five years than in the previous fifty. It is highly important that such agents as this, whose national contributions were of such magnitude and of such a notable standard of usefulness, should be harnessed to the work of reconstruction; that advantage should be taken of the increased knowledge gained of their abilities; and that their possibilities of future service should be exhaustively explored. Especially is this necessary at this time when our national position demands that every individual shall give his best efforts, and that every piece of machinery and every natural resource shall be developed and utilised to their utmost capacity for increasing production. This, indeed, is the text of the utterances of statesmen, employers, and of leaders of labour. With a unanimity which is as remarkable for its spotaneity as for its widespread character, the call is for production, increased production, intensive production. Our Chairman of this afternoon (Sir Robert Hadfield), when recently welcoming the Prime Minister to Sheffield, put the case very concisely and definitely when he said: "The world cannot get on its feet again until we recognise the principle of supply and more supplies." To employers and to employees the call comes alike. The responsibility belongs to both capital and labour; and the opportunities for meeting the national demands are available to both parties in industry. The manufacturer who deliberately keeps a machine idle, or who neglects to install the most efficient and modern machines, is as unpatriotic as the worker who "slacks."

The nation at present is not paying its way; our expenditure is greater than our income, and a heavy load of debt is still accumulating. We must recognise that the war destroyed goods and material worth probably £50,000,000,000, and reduced man power, which is the power of production, by probably 10,000,000. Of these losses, both in material and men, Britain willingly gave her full share.

To the aim of improving our national position, the best thought and energy of us all must be directed. We *must* have more output—more coal, more bricks, more cloth, more ships, more engines, more foodstuffs, more everything! It is only in this way that the brighter England can be realised, that prices can fall, that taxation can decrease, that industrial conditions can become stable, and that we can reap the great harvest that awaits us. The whole world clamours for the products of our factories. We have the supreme opportunity of our history. The next few years hold promise of being the greatest in British trade. Everything is contingent on, first, exercising a reasonable economy; and, secondly, and perhaps paramountly, producing more. He who can make "two blades of grass grow where only one grew before" was never worthier of the thanks of the community than now.

I think there will be agreement with the general survey of the position which I have so far made; and so we may turn from the general to the particular.

Let us look directly to the contribution which coal gas offers to the manufacturer and to his employees in their joint efforts to solve the great national problem of increased production. Many agents will need to be called in to assist, but none has a greater willingness nor a greater ability to serve than the commodity we are considering this afternoon. It touches the life of the community at every point; its ramifications extend directly or indirectly into every field of industry. I want to consider its services to the manufacturer and his employees and to the nation in its great task of economy, and the upbuilding of a stable economic position.

In the time available it is clearly not possible to deal with all branches of industry. The complete story, though full of interest, would be far too long for one paper. I shall therefore largely confine myself, as in my last paper, to the subject of the heat treatment of metals, as an example of the aid which gas contributes in all manufacturing processes. The output of machinery of all kinds and types is urgently needed to-day, as it is by its help that we can compensate in considerable degree

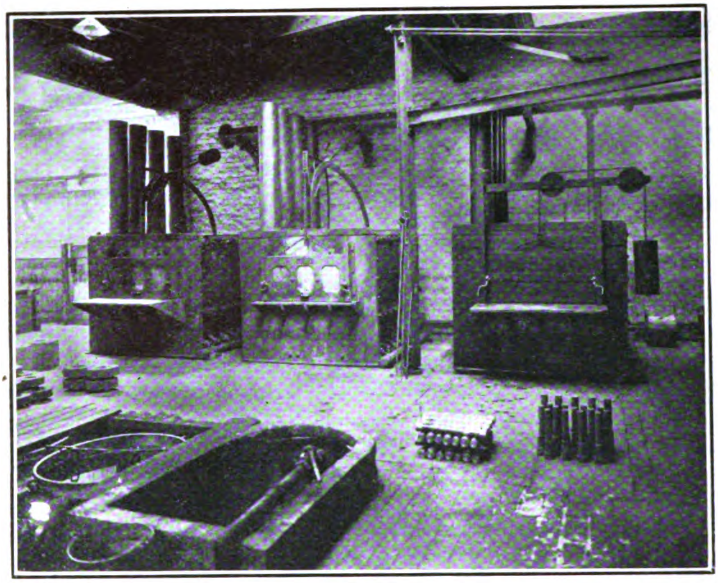

Fig. 1.—Richmond's Natural Draught Oven Furnaces at a Machine-tool Works.

methods are being adopted with the object of eliminating waste; the day of the monumental "scrap-heap" is passing. Scientific organisation has shown the way to the avoidance of "rejects" and "faults"; to the utilisation of "waste" material. As an example of the latest methods in the elimination of waste, we cannot do better than look at a heat-treatment shop of one of the leading firms of machine-tool makers (Fig. 1). It is especially fitting that we should take this as our first illustration in view of the supreme place (as already mentioned) that machinery must take in all efforts to improve production. It is partly to a larger use of modern machinery that we must look for enhanced results, and upon the quality and quantity of its production all other industries are dependent. It is therefore satisfactory to reflect on the large number of makers of the highest grade of machine tools who rely on gas for the careful heating necessary for their production. Parts for machine tools require a high standard of mechanical accuracy, and obsolete methods of heat treatment are an obstacle to the attainment of this. It will be noticed at once that all furnaces are fired with coal gas, the reasons for which will be apparent when we consider the intricate process of the heat treatment which is necessary for gears. These are first annealed at 750° C., for six to eight hours, and slowly cooled. They are then, after other processes have been carried out, carburised at 900° C., given four hours' soaking, and allowed to cool down. Each gear is then reheated—first at 850° C., and quenched in oil; and again at 750° C., and quenched in oil. This method has been found to reduce to practically nil the number of rejects for distortion; such large gears as 14-in., and even 18-in. diameter spur wheels being successfully treated.

Another important part of a machine tool, viz., the spindle, calls for very exact and scientific heat treatment. It is carburised at 900° C. for six hours, and cooled out. After further machining, the spindles are reheated in the furnaces (shown) at 850° C., and

for the loss of labour in the war, the reduction of hours per week, and the natural inclination of workmen to desire less strenuous occupation. The heat treatment of metals is, therefore, of primary importance in assisting the output of machines, tools, and labour-saving and cost-economising devices. All the industries of the country, great and small alike — cotton, wool, cloth, leather, glass — could, did time permit, be similarly passed in review, and the results of increased production by the use of gas, which I shall show in the case of the metal industry, equally apply to any and all of them. Heat is a universal necessity in manufacture, and coal gas is the most adaptable and efficient means of providing that heat, and it enables the fullest possible value to be obtained from the coal used.

Dealing, then, with the question of how gas can help production in the heat treatment of metals, I will, for convenience, divide my remarks under four heads:—

1. The eliminating of waste;
2. The cheapening of production;
3. The "speeding-up" of output;
4. The human element, improvement in working conditions;

all of which, in their respective spheres, mean increased production.

1. The Eliminating of Waste.

This is a very vital component of the effort to improve output. Waste means loss. Modern

quenched in water; and again reheated at 750° C., and quenched in water. Many other parts used in modern machine-tool production are also heat-treated in the furnaces portrayed —such as ball and twist races, indexing parts of turrets, springs, plungers, worms and worm wheels, all types of speed-changing gear and clutches, etc.

You will, I am sure, have been impressed by the importance of the heat-treating operations, by the stress laid on the attainment and maintainment of exact temperatures previously defined as necessary for the perfect product; and the same applies to every trade or industry where heat treatment of metals is necessary. It can readily be seen that it is the easy and perfect control that gas affords that enables such an exacting standard to be met continuously, and such excellent results to be obtained day in and day out, with a minimum of waste.

As another illustration of the help to increase production by the avoidance of losses, I would refer you to the motor industry. On the screen is a picture of the heat-treatment department of a world-famous motor-engine works (Fig. 2). In this class of work, as will be readily understood, such vague terms as "dull red" or "forging heat" are not admissible, meaning, as they do, anything within a range of 40° to 50° C. Operations have to be carried out at a definite temperature; and the limits allowed are within a very few degrees. If these narrow limits are exceeded by an infinitesimal amount the component part must be scrapped. It is therefore of vital importance to output to see that variations of temperature do not occur.

For this reason I think it will be of interest to you to note briefly the steps in the heat treatment. Normalising is the first operation. The part is heated to 780° C., and quenched in oil. It is then heated to 830° C., and again quenched in oil. The final heating is at 560° C., and thereafter the shaft is quenched in water. The stamping is made sufficiently long to allow test-pieces to be cut from both ends. A test-piece is turned from one end. This piece is cut into two, and one portion is tested for tensile strength, and the other is subjected to an impact test. The test-piece from the other end is tested for fracture. In addition to these tests, a "Brinell" reading is taken on each end of the shaft proper. This treatment is designed to guarantee that all parts of the shaft have been subjected to the same heating conditions; and after it has been completed the rough machined stamping is passed into the machine shops for finishing.

The refinement of heat treatment, it will be seen, is remarkable; but I am assured that, thanks to the constancy provided by the gas furnace, the number of "rejects" is a very small percentage of the total output. A word or two on the design of the furnaces (shown) will be of interest. They are chiefly of the natural-draught regenerator type, a cross-section of which is now on the screen. Special high-power Bunsen burners are employed, the burner mouths being sealed from the air at the point of entrance to the combustion chamber. Primary air is admitted to the burner, and controlled by an air-adjuster; while combustion is supported by air (pre-heated by radiation

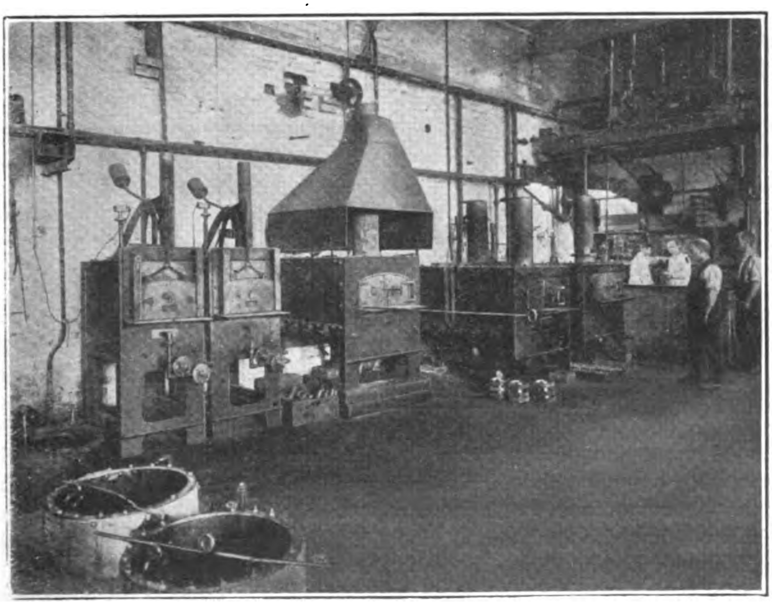

Fig. 2.—Heat-treatment Shop of a World-famous Motor-engine Works.

from the floor of the furnace) entering the combustion chamber by a series of air-nostrils. The next picture of this furnace enables me to point out these secondary-air valves more clearly. These valves constitute a vital part in the regulation of an even temperature throughout the whole oven, which uniformity is assured by this type of furnace. It will be observed that every burner has its own secondary-air valve, and it will be appreciated that this arrangement enables exact adjustments to be effected with facility.

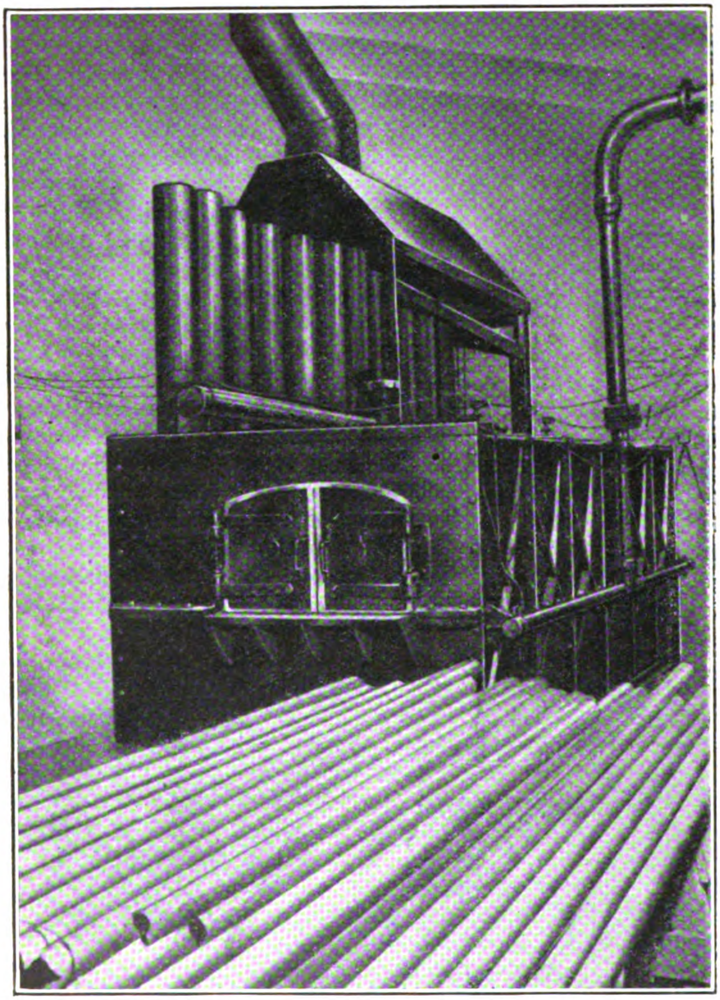

FIG. 3.—RICHMOND'S "L.P.G.A." OVEN FURNACES FOR ANNEALING 7-TON CHARGES OF HIGH-SPEED STEEL.

I have dealt briefly with the avoidance of waste from losses in the work undertaken, which has been accomplished by ensuring correct temperatures by the aid of such an easily manipulated fuel as gas. There is another element of possible wastage, however, that must be considered, viz., the spoiling of the work by incorrect atmospheric conditions in the method of heat treatment. All interested in the numerous thermo-treatments of steel will be aware of the emphasis placed on this point by experts. A decarbonising atmosphere, for instance, in the treatment of a cam shaft would result in the complete waste of much time, labour, and highly expensive material. Similarly, a reducing atmosphere at the wrong time is fatal to the accurate results required. In this connection, I do not know of any fuel which can give more satisfactory results than gas. Undoubtedly one of the main recommendations for gas for Sheffield steel works, and indeed for all treatment of metals, is the ease and certainty with which the conditions desired can be realised — not by guess work or exhaustive trial, but by simple adjustment of the furnace, and this obtained day after day, exactly the same, without variation. The picture on the screen (Fig. 3) is of a furnace annealing high-speed steel in Sheffield (in which city, I may mention, over 2,000 gas furnaces are in use). You will be interested to know that this particular furnace, up to the time the photo was taken, had annealed 311 charges, of about seven tons per charge, the aggregate weight, therefore, being approximately 2,200 tons. During the whole of this work, which was carried out at a temperature of 1,000° C., the only attention required by the furnace was the cleaning of the flues and the replacing of a few guard tiles, which were very small matters. The type of furnace shown by this slide is the patent "L.P.G.A." (low-pressure gas and air), and with this design

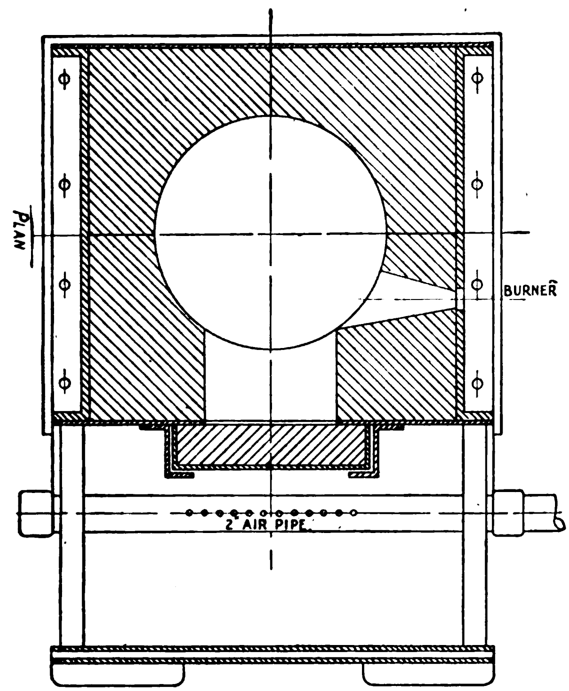

FIG. 4.—SECTIONAL VIEW OF "ROTOFLAM" TOOL-HARDENING FURNACE (Thompson's Patent).

any required metallurgical conditions can be secured with a minimum of adjustment.

Still proving the point of the elimination of waste, I take as another example the hardening of high-speed steel cutters, tools, etc. This is a highly skilled operation, and one in which expensive losses can easily occur, the cost of the articles treated often running into many pounds each. You will be interested in quite a new and improved type of furnace, as seen in the sectional drawings (Figs. 4 and 5). It is known as the "Rotoflam" (Thompson's patent). The furnace chamber is circular, and is heated by gas and air blast burners, two of which are used — one at the top and one at the bottom of the chamber, and equidistant on the circumference. The flame from the burners encircles the inside walls of the chamber, and generates a heat suitable for any class of high-speed steel. The point I particularly wish to emphasise is that there is no direct flame contact, all the heating being by radiation. Therefore there is no excessive heat at one point, and a gradual soaking heat is ensured. The most delicate articles may be treated within the finest limits of temperature without fear of burning. There is no flue or chimney in this furnace, the exhaust gases being expelled automatically through the mouth, thus preventing any free air from outside entering the chamber and oxidising the steel. It will be realised how completely this well-designed furnace eliminates the possibility of spoilt work.

The next slide shows a fine installation of a somewhat different type of high-speed steel furnace — viz., the Brayshaw. These are very well known and largely used in the steel industry, and produce remarkably good and consistent results.

The upper chamber is heated by waste heat from the lower, and serves for pre-heating tools, etc., before they are put into the lower furnace, raising them gradually to a medium temperature preparatory to the final quick-heating required to bring them up to the high

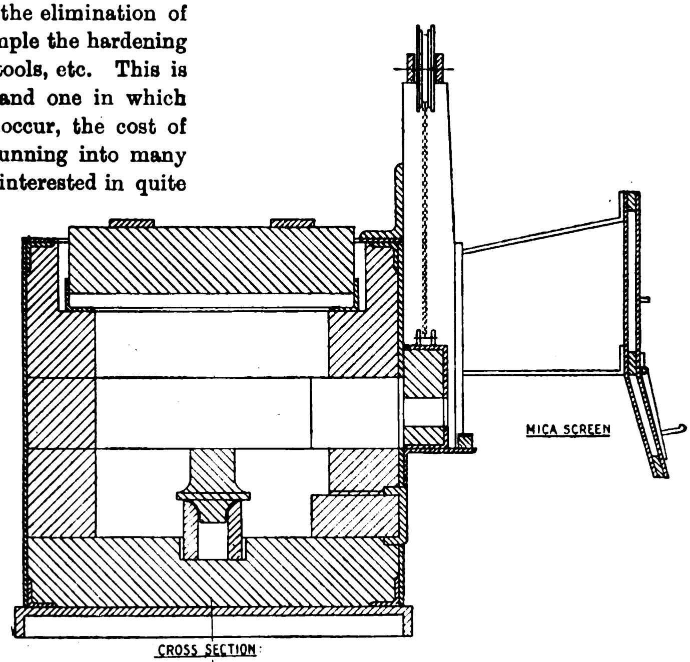

FIG. 5.—SECTIONAL VIEW OF "ROTOFLAM" TOOL-HARDENING FURNACE (Thompson's Patent).

temperature necessary for hardening. By means of this furnace the skilled operator is enabled to ensure the production of good tools giving the maximum of service, and to avoid the waste of expensive material and time due to under-heating or over-heating in hardening, etc.

I think I have demonstrated—I hope to your satisfaction—how gas can help in eliminating waste in processes of manufacture in vital industries, and by this positive reduction of waste materially assists in increasing production. I will now turn to the equally important subject of

A. *Capital Outlay.*—Where gas is employed, the building of a smoke-stack is not required. Gas furnaces do not involve any structural alterations to the factory, nor special foundations; while their initial cost is in many cases lower than solid-fuel furnaces. The fuel has only to be paid for as it is used; and there is no big stock of fuel to be stored, with consequent interest on the capital outlay.

B. *Labour.*—To-day labour has (so to speak) a capital cost exceeding anything that has obtained in the past; and this fact must also alter our point of view when considering reduction of

FIG. 6.—A TYPICAL HEAT-TREATMENT SHOP, SHOWING RICHMOND'S OVEN FURNACES.

2. THE CHEAPENING OF PRODUCTION.

To lower the cost of his finished product must be the constant study of every manufacturer, as we realise that high prices mean less purchasing power, and less volume of output. Gas places us all under a debt for the service it renders in cheapening production. A glance at the neat, compact, self-contained gas furnaces seen in the shop on the screen (Fig. 6) convinces one on this point. The economy that issues from the use of gas may be detailed under four heads.

costs in relation to increased production. With gas, no stoking or clinkering or removal of ashes is required; and labour—highly-paid labour to-day—is saved. No labour or cartage has to be expended in transporting fuel—a further considerable saving. The choice for the position of the gas furnace is practically unlimited. It can be brought into proximity to the machine worker, and thus intermediate handling is saved. For example, the furnace (shown on our next slide) is used close up to the hammer, and so dispenses with considerable

labour. This particular furnace is heating brass discs 3 in. in diameter by $\frac{3}{8}$ in. thick at the rate of six per minute.

C. *Cost of Fuel.*—The use of gas renders unnecessary storage accommodation for fuel. Coal and coke stocks require valuable space, and incur rent without directly earning anything for the area occupied. In the running cost of fuel I have two examples to touch upon briefly—both from a large engineering centre in the north—comparing first the cost of gas with oil, and then with coke. The first processes are the heating of spring buckles prior to pressing on to the spring, and the heating of round longitudinal stay-rod ends for locomotive boilers before "heading." The gas furnace used for this work is illustrated on the screen; and the cost of gas consumption is 1*s.* 3*d.* per hour, as against 3*s.* 1½*d.* per hour with the oil furnace it displaced, and as prices were on the rise the comparative difference is actually greater than these figures represent.

This same industrial area specialises in the manufacture of colliery tipping tubs; one of the requisites for this work being the regular provision of ½-inch rivets. Gas is proved to be ideal for this process, giving a constant supply, unvarying in quantity and quality, hour by hour, and keeping pace with the demands of the riveters. Gas performs the work, too, at a minimum of cost for fuel;

PERCENTAGE RISE IN COST OF RAW MATERIALS ETC.

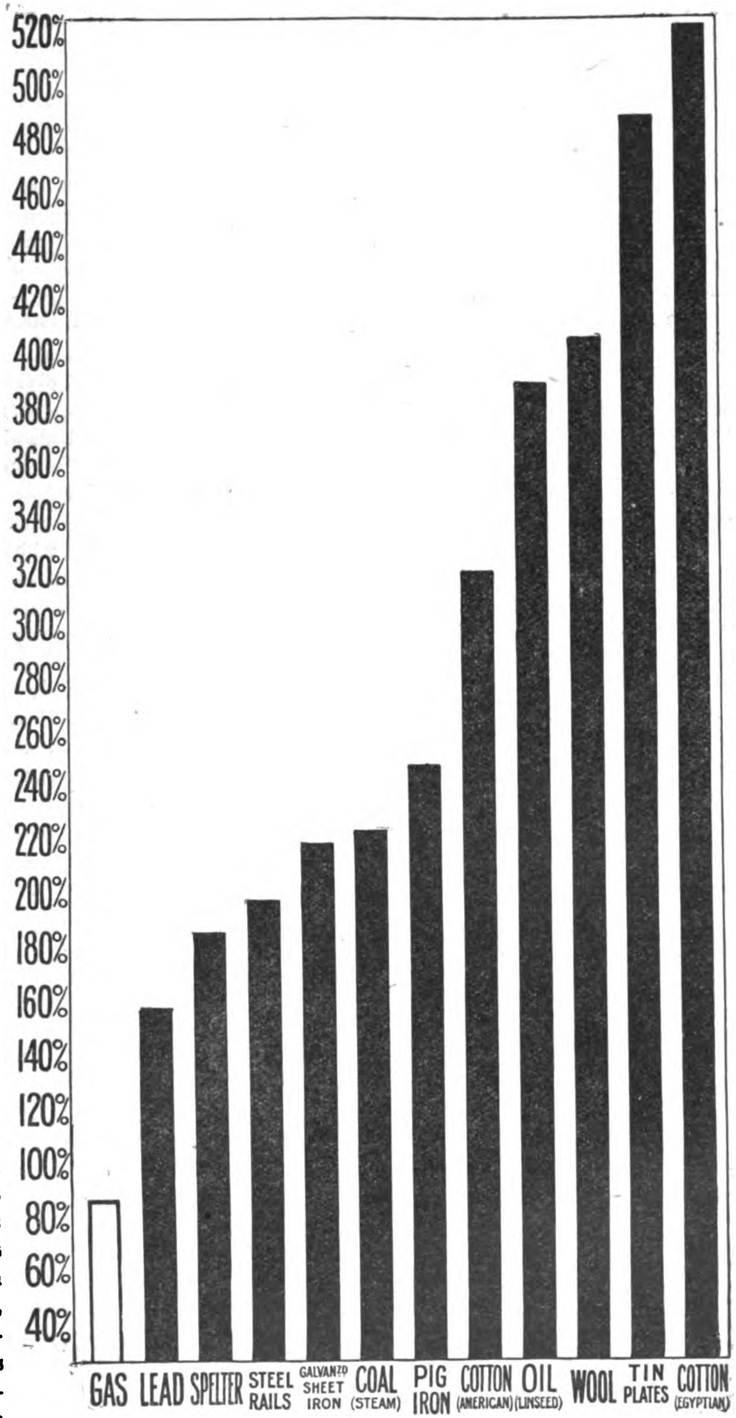

FIG. 7.

the figure being 2s. 9½d. per 8-hour day, against 5s. 7d. per day for coke for the same output. Those are tangible differences which need no comment.

It will be opportune here to refer to the price of gas. I have prepared the chart which forms our next slide, showing that the price of this commodity has increased since July, 1914, by a very much lower percentage than raw materials, &c. (Fig. 7). The price of gas has made a contribution to the increased costs of manufacture to a very much smaller extent than all other commodities, and is to-day comparatively the cheapest of the factors that make up the cost of the finished product. The percentage increase in the price of gas—viz., 80 per cent.—is based on the pre-war prices compared with the prices on December 31st last of all gas undertakings in the United Kingdom making over 300 million cubic feet per annum.

D. *Factory Floor Space.*—Lastly, the gas furnace, self-contained and compact as before mentioned, economises that very valuable asset —factory floor space. This provides the means for an increase in output per unit of factory area, without any corresponding increase in overhead charges—indeed, obviously without any increase at all in rent, rates, etc. This economy is pictorially shown in the next slide. It will be noticed that three gas furnaces (the correct dimensions of which have been outlined) only occupy the same space as one of the coal-fire variety, with its indispensable coal-storage space, which, as previously remarked, is not called for with gas. As each of the gas furnaces has precisely the same oven dimensions as the coal-fired one, this at once increases the output threefold for the same floor space.

From these facts it will be apparent to what a large extent gas can claim to reduce the cost of the finished article. There is a saving in capital outlay, in labour, in fuel, and in factory space, all of which react on the cost, and consequently on the selling price and the output.

Having now dealt, first, with the manner in which waste and rejects are eliminated, and second and more briefly with the reduction in the cost of production, I wish now to show how the actual output of the product is "speeded-up" by the aid of gas.

3. The "Speeding-up."

It will be apparent that the sections into which I have divided this paper necessarily slightly overlap, and that some of the points I have already dealt with in Sections 1 and 2 have their direct effect on output. I do not think I can better illustrate my point of "Speeding-up" output than by giving some general particulars and examples which have come under my personal notice.

The first slide in this section shows a battery of gas furnaces which superseded coal furnaces for annealing purposes. The results of this change were really extraordinary. It was found that the gas-fired oven (of the same size as the coal furnace) could take a load 33⅓ per cent. greater than the coal-fired, owing to its construction and uniformity of temperature. In the deposed furnaces, owing to the "cold mouth," the load could not be placed within 18 inches of the door. Further, in the case of gas, the time the articles were in the furnace was reduced by 33⅓ per cent. This, as you will see at once, doubled the output per furnace, or, conversely, halved the time per unit of output.

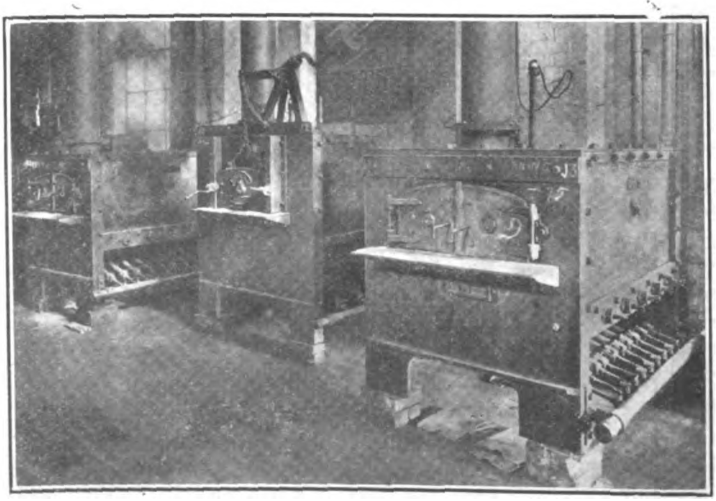

Fig. 8.—Natural Draught Gas-heated Furnaces for Annealing.

Let us take as another example an annealing process, as performed in the installation now before you on t e screen (Fig. 8). This is a case in which fairly bulky articles had to be heated, in large numbers, at a fixed temperature, with a limit allowance of a very few degrees up or down. To execute the desired quantities, it was

necessary to fill the furnace completely at each charge. The articles were stacked on racks or trays, and these furnaces filled from the end to the mouth, so that the door could just be closed. Upon the completion of the heating period, every one was perfectly annealed, and tests made on those taken from the sides, middle, or ends showed no variation, and all equally passed the stringent conditions enforced. Had there been any variation in the temperature over the oven, those unequally heated would have been rejected, would have had to pass back for re-treatment, would have lowered the output, and thrown out of gear all the fine organisation of the works that was based on the speedy and continuous passing of the article from one class of operation to the next.

This leads me to another point—viz., that, by the constancy of action of the gas furnace, the time required for the heating operation is definitely ascertained, the work comes through at a uniform speed, and the works manager can safely organise his other departments without any uncertainty as to his supply of heat-treated materials. The furnaces in the next picture are engaged on an annealing process that is timed to take thirty minutes for actual heating. Allow five minutes for charging and five minutes for unloading, and the works manager knows that every forty minutes each furnace will give a definite output—not perhaps, not sometimes, not dependent on the human element, not varied by any external circumstances, but always and all day. This is a striking example of the service which gas renders. The next slide is a reproduction of a sheet taken from a recording pyrometer, and it indicates at a glance the regularity with which the desired temperatures were obtained for successive charges in a gas furnace, emphasising the illustration I have just given.

My next slide shows a sectional view of a "L.P.G.A." (low-pressure gas and air) Furnace (Richmond's patent), and as I have some very convincing figures to give of the working of this type of furnace, it will not be out of place to spend a minute or two in describing the principle of working. It will be observed that it is "over-fired"—*i.e.* the gas supply at normal town's pressure is led through ports at one or both sides, where it comes into contact with the air (supplied at approximately 2-in. water-gauge) obtained from a small fan, which air has been previously well pre-heated by being taken through the opposite side of the furnace in fire-clay tubes and then passed along the bottom of the furnace in close proximity to the hot waste products. Combustion takes place inside the working chamber round the furnace walls, the usual separate combustion chamber being absent. The flames produced keep well up and sweep round the arch. The products of combustion then pass to the opposite side of the furnace, are carried under the floor and up the other side away to the flue. All the waste heat possible is utilised in pre-heating the air, and this promotes economy and efficiency.

The flues are required simply to convey away the products of combustion (not to create a draught), and adjustable dampers are provided, so that there is no actual pull from the furnace chamber to the outside air. With pressure inside the furnace, air cannot enter through the door or any other orifices even when the former is opened for any purpose.

To come now to the actual performance of this furnace, I have been furnished with figures, which are strictly comparative, showing its superiority over a certain installation of solid-fuel fired furnaces in an important engineering industry. The operation is the normalising of a certain small article which is hammered out of mild steel wire. Owing to the necessity for absolute accuracy and dead even heating the solid-fuel furnaces were condemned and replaced by others fired by gas, with the result that not only was the heating process rendered absolutely satisfactory, but the output was increased to an astonishing extent. There were formerly four solid fuel furnaces, each measuring 6 ft. 9 in. long × 3 ft. wide × 1 ft. 9 in. high; and at each charge 6,000 articles could be treated—two charges per day being secured, or an output of 12,000 articles. The four "L.P.G.A." furnaces (of precisely the same internal dimensions) which were substituted for the coke furnaces took a charge of 10,000 articles instead of 6,000, and four charges per day were secured against two; thus making a total output for the day of 40,000 articles, as against 12,000 with the coke furnaces, or an increase of 233 per cent.

Further, this increase was obtained with actually a proportionately reduced cost for fuel; the gas consumption per charge costing 12*s.* 10½*d.* (with gas at 3*s.* 7*d.* per 1,000 cubic feet, which is a fairly high rate for industrial purposes), as against 13*s.* 1½*d.* per charge per furnace with coke. As the gas furnace took a charge 66 per cent. greater, the actual cost for fuel was 70 per cent. more with coke. I have

not been able to obtain a photograph of the actual installation just described, but the next picture shows us one of the same type of furnaces. The one seen (Fig. 9) is used for

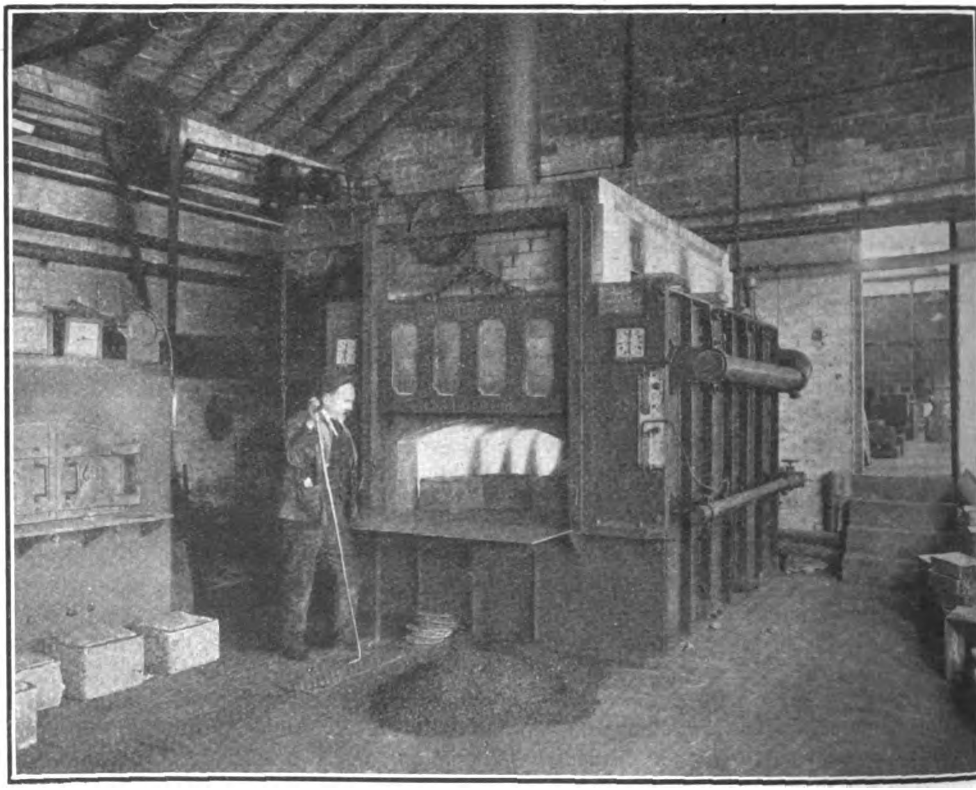

FIG. 9.—RICHMOND'S PATENT SOLID FLOOR "L.P.G.A." OVEN FURNACES FOR CARBURISING 12-CWT. LOADS AT ONE CHARGE.

carburising. The weight of a full charge of the parts to be treated is 12 cwt., and the operation carried out at 920° to 940° C.

The users have provided me from their experience with two very strong points in favour of the gas-fired appliance, in addition to the increased output, viz., that the life of the carburising pots which are used in this process, whatever fuel may be used, has been increased by 50 per cent. by the use of gas, and that the cost of furnace repairs and replacements has been enormously cut down—in fact, the furnace seen on the screen has been running *daily* for nine months (the capacity for continuous work is a most important matter in works production), and has not yet cost a penny in any way for maintenance.

As another example of the speeding-up of output procured by the use of gas, I am able to give very complete results of actual working practice with a Davis' patent "Revergen" furnace, as compared with the coal-fired furnace which it supplanted. The principle of the "Revergen" furnace, as shown on the screen (Fig. 10) may be briefly stated to consist of a system of gas-firing by means of which heat losses, by way of furnace flue or flues, are reduced to an insignificant minimum; and the thermal energy thus recovered is utilised almost exclusively for the practical purposes of the furnace. The particular furnace in question was used for heating heavy forgings at a marine engine works; and I may state that the figures (see p. 357) both for gas and coal were provided by the users, the tests being made by them under ordinary working conditions.

It will be seen that the net output was over 10 per cent. higher, while the net cost of fuel and labour was reduced by over 51 per cent.

Incidentally these figures provide a very interesting illustration of another point, viz., the conservation of coal effected by the use of gas. It will be observed that in the coal furnace 55 cwts. of coal were completely destroyed per

Coal v. Gas for Forging.

One Week's Work with Coal.

Forgings produced, net = 65 cwts.

Costs:	£	s.	d.
9 tons of coal at 39*s*. per ton . . .	17	11	0

Output increased by = 10·76 per cent.
Cost per ton of forgings, reduced by = 51·6 per cent.
Percentage of virgin coal saved = 80 per cent.

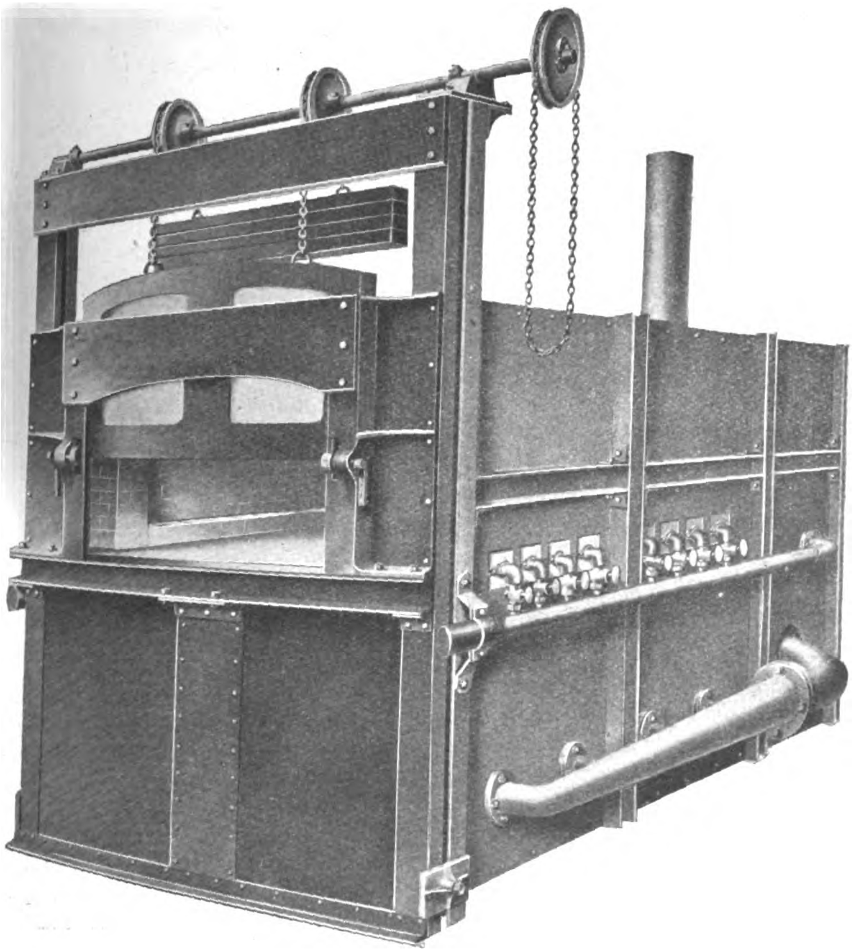

Fig. 10.—The "Revergen" Oven Furnaces (Davis Furnace Co.'s Patent).

ton of forgings. In the gas furnace 15,055 cubic feet of gas were used per ton of forgings. Now, assuming the gas works produces and sells 12,500 cubic feet of gas per ton of coal carbonised—many are, I ought to say, doing much better than this where there has been the opportunity of adopting the more modern gas-making process—each ton of forgings entails the carbonisation of only 1 ton 4 cwt. of coal, as against the 2 tons 15 cwts. directly used and

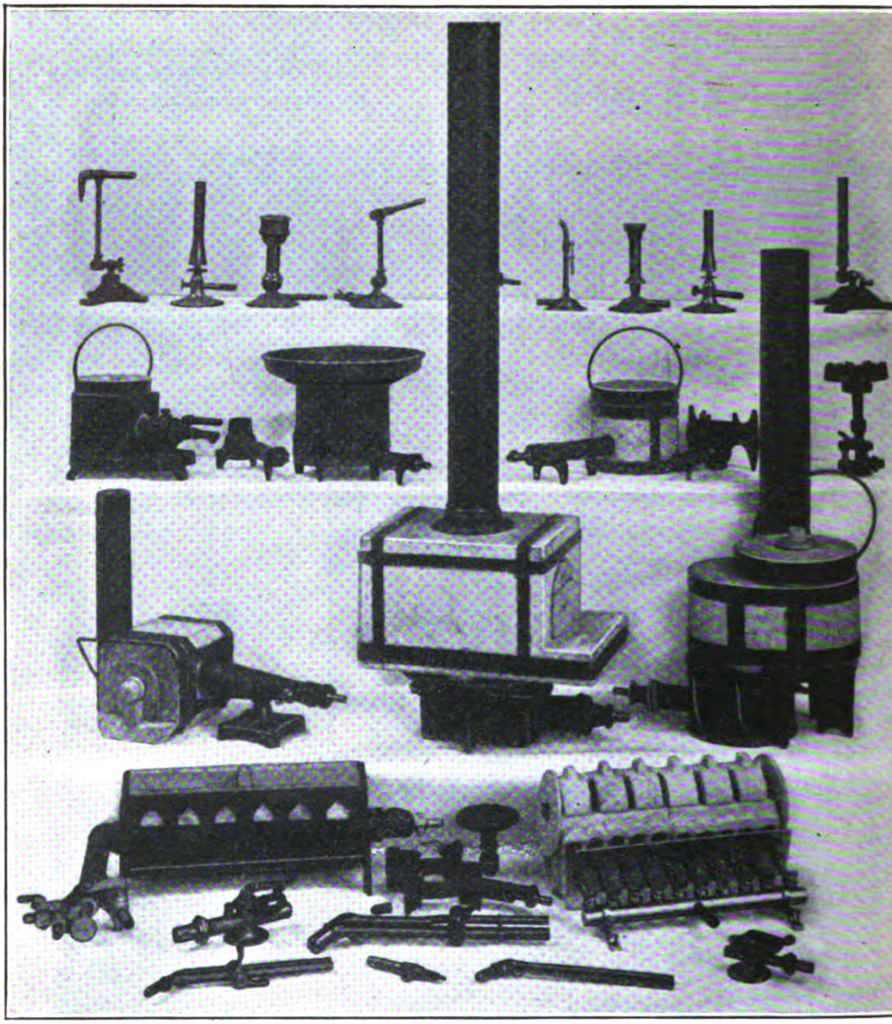

FIG. 11.—GAS-HEATED LABORATORY APPLIANCES (Fletcher, Russell & Co., Ltd.).

completely destroyed by the coal furnace; thus directly saving 1 ton 11 cwts. of virgin coal, plus 12 cwts. of coke rendered available for sale, a total saving of 43 cwts. out of 55 cwts.

Further, after the gas works has carbonised the coal, there are the valuable secondary by-products still left available for use, namely, tar, sulphate of ammonia, and a variety of valuable derivates from both the gas and tar. This demonstrates in a very forceful manner the national importance of an extended use of gas, a subject to which I shall refer again in a few minutes. Another example of an industry which has recently found the advantage of gas for increased output is that of the annealing of grey iron castings; and the following examples will be of great interest to those engaged in this work. The process consists of packing these castings into iron pots, surrounded by a suitable inert material, such as sand, bringing to a temperature of 820° C., and maintaining it throughout for a period of three hours. The total gross weight of eight charges was 11,753 lb. The gas consumption per lb. of gross load was 1·89 cubic feet and 3·9 cubic feet per lb. of castings. These figures are, I am sure you will agree, very convincing testimony to the use of gas for this work.

Our next slide (Fig. 11) shows a group of gas-heated laboratory appliances (by Messrs. Fletcher, Russell and Co., Ltd.). I should perhaps have referred to this earlier in the paper, in view of the extent to which the efficiency, economy, and consequently output of modern

factories depend on laboratory work and the researches of the works' chemist. Gas for experiments and investigation is, of course, not a new development. But appliances have been perfected, and fresh ones introduced; and the comprehensive series seen on the screen shows the wide use of our commodity for this highly important work.

My next example of increased output as a result of gas installation deals with metal-melting. No furnace has made as a commercial proposition greater progress in the last few years than the gas-fired crucible furnace. It is not only now possible to use gas efficiently for this purpose in that it bears favourable comparison with solid fuel, but it shows many substantial advantages over its earlier rival. One of the most exhaustive comparative tests made of the capabilities of coke and gas for melting was by Mr. G. B. Brook at the Sheffield University, who reported the result in a paper before the Institute of Metals in 1917. The gas furnace used was of the standard pit type as seen on the screen.

"In order to make the test as drastic as possible, cupronickel (80 : 20) was chosen as the test alloy, in view of the high temperature required for this particular material. Every endeavour was made to ensure that the work should be on as large a scale as possible, closely following commercial practice, so that the results obtained would be accepted by manufacturers as a guide to what might be expected in their own melting-shops. During the ten working days covering the period of the test, the total weight of metal that went through the furnace was 51 cwts." The results proved conclusively that gas for melting metal is satisfactory from every point of view. The necessary high temperature of 1,400° C. was readily obtained; and the average time of the 56 lb. load in the gas furnace was 52 minutes, against 82 minutes with the coke furnace. It was found possible on two of the days out of the ten to secure twelve heats with the gas furnace in less than ten hours, as against the usual practice of five heats with the coke furnace. The average life of the crucible was longer in the gas furnace; and the lining of the furnace stood the test satisfactorily. The mechanical losses in charging and drawing were less than ½ per cent.; the best practice with coke being 1 per cent. The quality of the metal produced was everything that could be desired.

On the questions of labour charges and cost of fuel, Mr. Brook's results are of great interest. He says: "On a large installation there would be a distinct advantage in favour of gas in the amount of labour required. Four coke-fired furnaces can be worked by three men. It would be possible to work a six-hole gas-fired battery with four men, even taking into account the extra mould preparation incident on the increased speed of gas-melting." In regard to consumption of fuel, the cost per ton of metal melted was 31*s*. 9*d*. and 36*s*. 4*d*. for gas and coke respectively. The prices of gas have risen since this test, but so have the prices of coke.

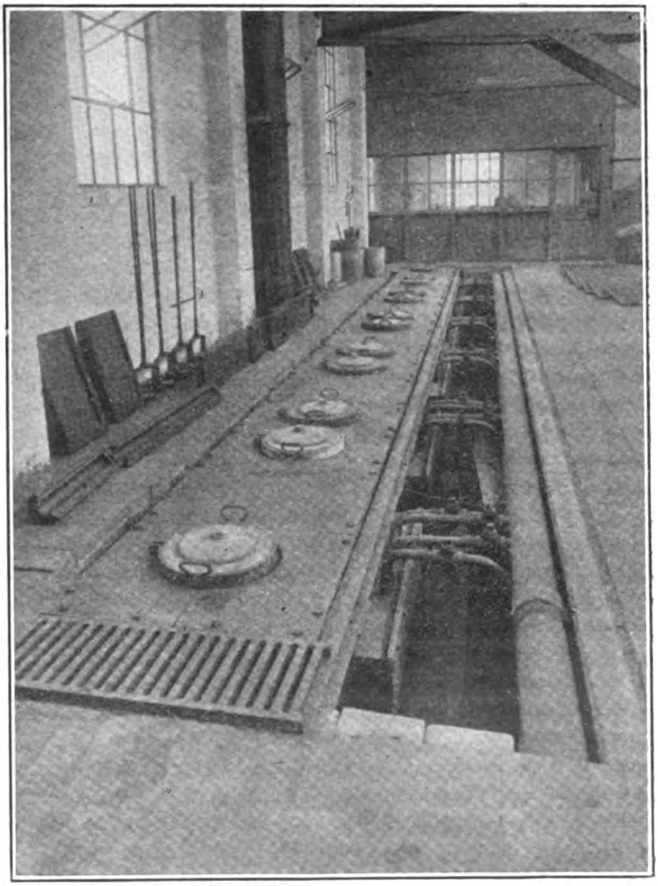

Fig. 12.—Twelve Pit-type Richmond's Crucible Furnaces.

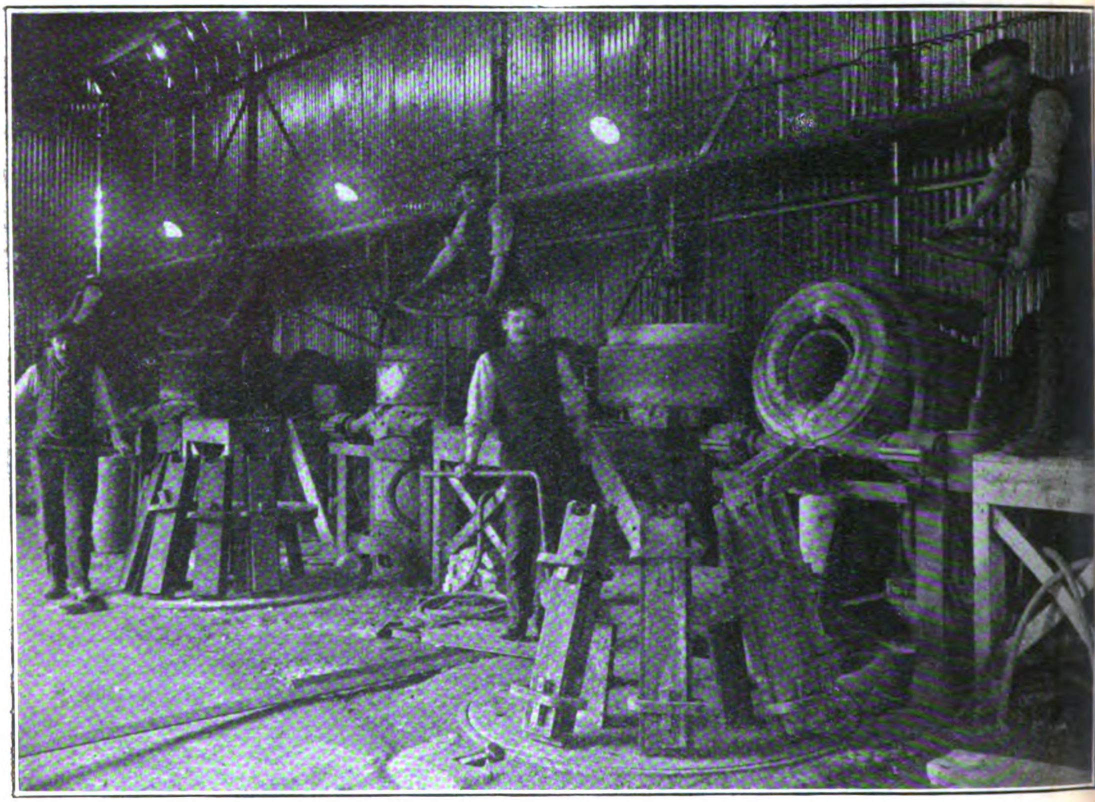

FIG. 13.—BATTERY OF "LIP-AXIS" TILTING CRUCIBLE FURNACES (John Wright & Co.'s Patent).

These figures were strikingly confirmed at a meeting of the Institute of Metals in a paper read by Mr. W. J. Hocking on metal-melting as practised at the Royal Mint. He gave results of five years' working with both gas and solid fuel; and it was found that the gas furnaces gave an increased output, for gold, of 88 per cent., up to, for cupronickel, 161 per cent. The average cost of fuel and crucibles over five years was £3 1*s.* 2*d.* in the case of coke, and £2 7*s.* 5*d.* with gas, per ton of metal melted. The number of men employed was actually 19 per cent. less with gas than with coke for the same output. This convincingly shows the saving of time, labour and material resulting in the larger output by the aid of gas.

The next slide shows us a fine row of pit-type furnaces (Fig. 12), installed for the purpose of melting a special alloy. Founders who have had similar furnaces in use for three years say they are still "perfectly satisfied. Two tons of metal were melted per week, 11 melts being carried out per 8½-hour day. The cost of renewals has been confined to replacing the top lids after the first ten months' use." This is convincing testimony to the commercial use of gas for melting. The next picture is of the furnace itself. In this type the air for combustion is pre-heated as well as the metal, and this accounts to some extent for its high efficiency and large output.

When large quantities of metal are to be melted, the furnace usually employed is of the Lip-Axis Tilting type (made by John Wright and Co.), as seen on the screen (Fig. 13). These furnaces, with crucibles up to 600 lb. brass capacity, work with incredibly low gas consumption. The next picture shows us a battery of these large furnaces.

An installation of furnaces of these big dimensions is an outstanding tribute to the progress made and the stage of perfection reached in the utilisation of gas. As Sir Robert Hadfield remarked on the occasion of my last paper, it would have been deemed incredible a few years ago that gas could be economically used for such large industrial work.

Instances such as I have given could be multiplied in all trades, but I think sufficient

evidence even from the comparatively small number of examples dealt with has been adduced to prove the value of gas in relation to increased production and output.

4. THE HUMAN ELEMENT.

One other matter (and that of considerable moment) remains to be mentioned in the short time I have at my disposal, viz., the human element in the factory — the worker. Mr. Hoover, the American statesman, recently advised Europe to "work harder." One phrase in his statement was "Many people in Europe are not at work." Now we are sure that Mr. Hoover did not forget, although he did not mention it, that the working power of Europe has been very seriously reduced by the loss of many efficient producers, and those the most vigorous of our manhood. As Great Britain lost 800,000 killed in the war, it would be a reasonable figure to assume, allowing for wounded and diseased, whose physical strength has suffered considerably, that we are poorer by the loss of a million and a half of workers. This is a very substantial reduction in our army of producers, and it is clear that, without other aids, and without greater organisation, the same output as before cannot be expected. This fact must be recognised in all our comparative statistics of total production. It points emphatically to the need for the use of every appliance that can assist the human factor in industry.

Mechanical aids, scientific management, modern machinery, a higher standard of health and efficiency, greater skill and knowledge, more extensive training and practical research work, must all be called in to the help of the worker and the improvement of the industrial output. I have already shown how gas can help in some of these things; and in concluding this section of my paper I want to present a few of the ways in which that servant of the nation assists in improving working conditions for the men and women in our factories. A better standard of living is called for—and rightly called for—and there is, in my view, much opportunity for ameliorating the conditions during the working hours, with far-reaching results. The strain will be less exacting, health will improve, efficiency will rise, production will grow, and greater prosperity for all will follow in a natural sequence. I do not claim—I could not attempt to do so—that gas by itself can solve all these problems. But it has its contribution to offer; and it waits to join many other agents in taking a step forward in these matters. For example, take the furnace which is used for the heat treatment of high-speed steel shown on our next slide (Fig. 14). In its construction the comfort of the workman has been considered in every possible particular. Observe the pipe mounted in front and directly below the mouth of the furnace. This is drilled with a series of holes through which a stream of

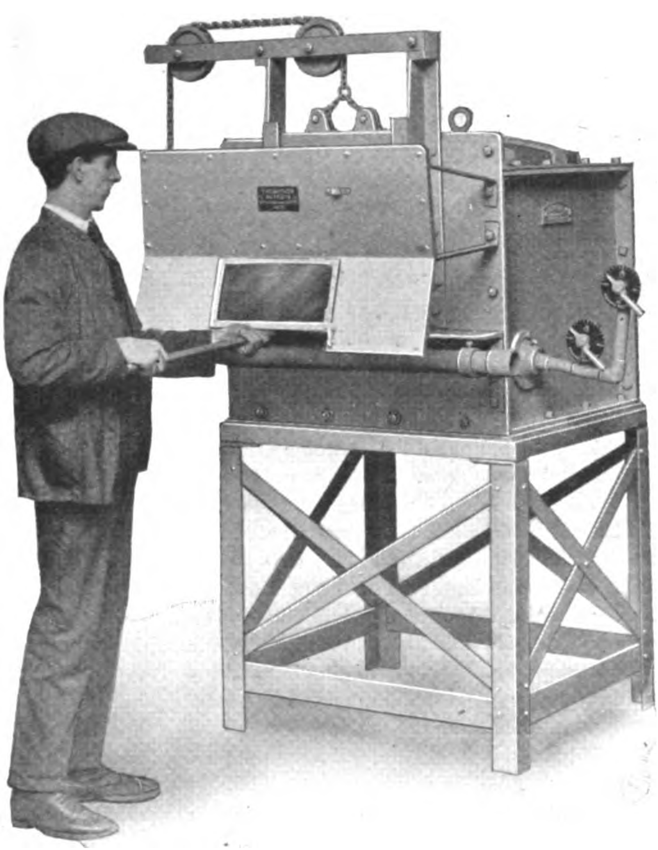

FIG. 14.—GAS AND AIR BLAST "ROTOFLAM" FURNACE (Thompson's Patent) FOR HARDENING EXPENSIVE HIGH-SPEED STEEL TOOLS.

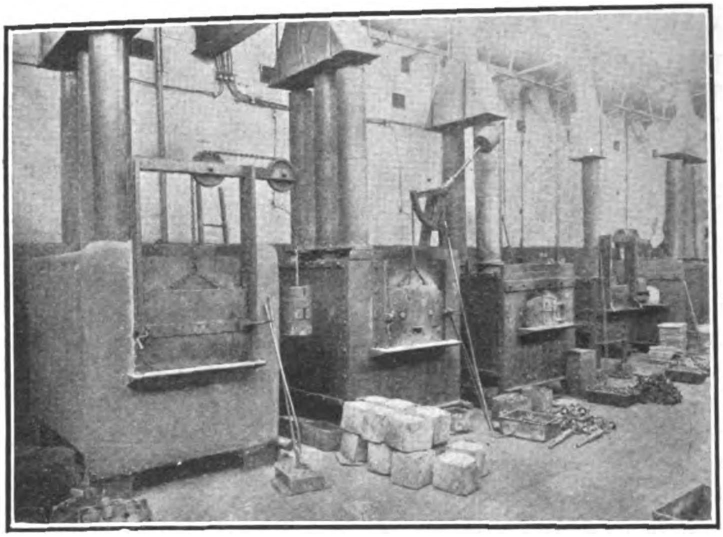

FIG. 15.—MODERN HEAT-TREATMENT SHOP EQUIPPED THROUGHOUT WITH GAS FURNACES.

air, delivered under pressure, forces the exhaust gases upwards and away from the operator, and at the same time keeps cool the tongs or the shank of the tool for ease in handling. As an additional protection an asbestos-packed guard, with hinged mica screen, is provided. No heat is radiated on to the operator as in the case of a swing-out door. These are all small matters, but it needs little imagination to conceive how much they add to the ease of operation, save the worker from discomfort, and enable him to maintain a high rate of output throughout the whole of the day. Again, look at the up-to-date heat-treatment shop which forms our next picture (Fig. 15). Even in this reproduction the air of cleanliness and lightness is apparent. The men themselves are ready to acknowledge the benefits derived from the gas-fired appliance.

The following is a sample of several similar reports that have reached me.

"When gas was being installed much opposition was shown by the men. They were conservative, as many workmen are, and were sure the furnace would not do the work. Now, after experience, I believe they would soon strike if it were ever suggested to go back to the old methods. They appreciate the greater efficiency, the cleanliness, and the labour-saving attributes of the gas-fired furnace."

Here is another (a cutting from a recent technical journal) describing a new installation of gas furnaces: "The workmen say that the conditions of labour are much better than in the old days. The plant is easier to control, cleaner to work, and the necessity to draw fires has been done away with."

Closely allied to, and indeed a natural corollary of the subject of improved workshop conditions and their effect on production, is that of general welfare work throughout the factory. I devoted a considerable portion of my paper in April, 1917, to this topic, and I will therefore only briefly touch upon it this time. It has, however, a direct and vital relation to the subject of increased production under consideration this afternoon. During the war "welfare work" received a remarkable impetus, and marked success attended its expansion. The form that this most frequently took — although in many factories this new principle in industry was developed to a very considerable extent — was the industrial canteen or works' dining-room, an example of which is seen on the screen. The results secured by, and the advantages accruing from, the establishment of these canteens have been very impressive. There has been a marked improvement in the health of the workers, with less sickness, and less absence and lost time; and a less tendency to alcoholism has been observed, all making for increased efficiency and larger output. Further, the substantial, nourishing, and reasonably priced meals provided by a canteen situated in the works have saved the time of the worker, given him a salutary mid-day change from the workshop, enabled the shop to be properly ventilated in the complete absence of the workers, and generally created an atmosphere of greater contentment and goodwill. These are solid and substantial advantages, and their effects on output are testified to from all quarters. This is undoubtedly a movement that possesses great possibilities for the future, and it is to be hoped that in all reconstruction proposals room will be found for this very helpful adjunct to factory life. It will be a great disappointment if the progress made in this

direction is not maintained, and very greatly extended, under peace-time conditions.

Gas is, of course, the chief fuel used in these canteens, and I show just one picture of a modern kitchen equipped throughout with gas apparatus (Fig. 16). The reasons for the choice of this fuel are fairly well known and obvious, and so I will not stop to discuss them again. I will, however, remind you that it received official sanction and encouragement, for the Committee on the Health of Munition Workers reported: "Gas cooking is usually preferred on account of cleanliness, efficiency, and saving of labour." Quite recently the National Kitchens Division of the Ministry of Food testified to the suitability of gas for the cooking of food for large numbers in the following words: "The National Kitchens Division has had extended experience of cooking appliances, and still advises the use of steam, when available, for heavy duty such as boiling pans. The Division's experience of electricity for cooking has been anything but favourable. Gas appliances are more constantly reliable, and much cheaper to install and maintain, and they consume less fuel."

We have now considered the worker during his labouring hours. But this section of my paper—the human element—would not be complete without a reference to the domestic side of his life—that is, to the home. The conditions there must directly and indirectly affect his health, his efficiency, and his ability to perform his daily work. This subject, however, requires an afternoon to itself, and I can only briefly refer to it now. The claims of gas for domestic purposes are so indisputable that its sway has become well-nigh universal. It is recognised that in the new housing schemes gas will play a leading part, as it provides the means whereby unnecessary labour is eliminated, economy is obtained, cleanliness and hygiene are assured, and the comfort of the worker, his wife, and his family is secured. Gas is an essential corollary to the raising of the standard of living, which we hope will ultimately lead to a ore efficient worker, and conequently a higher output. Incidentally, gas can, and will, aid materially in expediting and cheapening the actual building of the new houses for which the nation anxiously waits. Gas fires for rooms requiring intermittent heating, such as parlour and bedrooms, should be the accepted policy, and I am glad to learn this is recognised by the Ministry of Health. The use of the gas fire abolishes chimney-breasts and the large smoke-stacks necessary to carry off the products of combustion from coal fires. A glance at the two plans (prepared by the Nautilus Fire Company) now on the screen show clearly the saving in space and economy in building effected by the substitution of gas fires in place of coal. By installing specially-designed gas-flues (Fig. 17) in place of the ordinary 9-in. by 9-in. coal-flue the cost is reduced considerably, as they eliminate brick chimney-breasts, brick footings, foundation concrete, skew-back arches, trimmers, chimney-stacks, and, at the same time, reduce the amount of leadwork required in soakers, flashings, aprons, etc. After most careful estimates, it has been found that the net saving is £30 per cottage, after allowing ample for the provision of gas fires and gas supplies. On the 500,000 houses which were originally contemplated (the number is much greater now) the saving would amount to £15,000,000. Another important factor must be mentioned. By eliminating the chimney-breast additional floor-space of about 120 feet super is obtained and an increased cubical capacity of over 2,000 cubic feet per block of four cottages.

Fig. 16.—Gas-cooking Equipment in the Kitchen of the Bank of England.

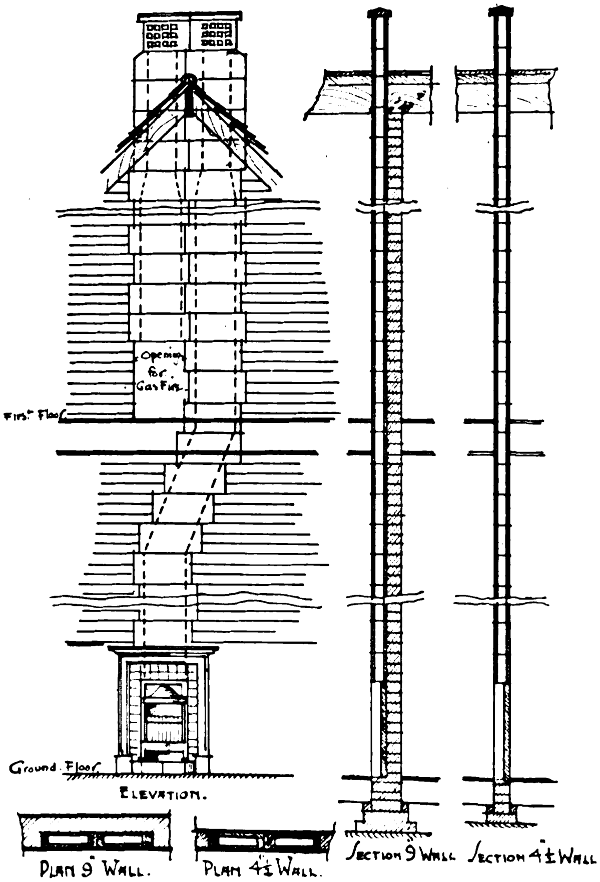

FIG. 17.—DETAILS OF CAST CONCRETE GAS FLUES AND TERMINALS (Nautilus Fire Co.'s Patent).

I have tried to show how gas eliminates waste in manufacturing processes, how it cheapens production, how it "speeds-up" output, and how it adds to the personal comfort and well-being, and thereby the efficiency of the individual. There are, however, other considerations which should not be left out. Our story does not end with the industrial benefit obtained by the use of gas, for it is the carbonisation of coal at the gas works that liberates the multitudinous and valuable by-products. It is surprising how little the public generally realise the need of eliminating, as far as possible, the wasteful method of consuming coal in its raw state, which, apart from its inefficiency, involves the absolute and entire loss of these by-products. This subject is entirely appropriate to our topic this afternoon, as the nation, in these difficult days, cannot tolerate loss in any form. It is not, too, as though we were losing something of little or no productive value. Take, for instance, sulphate of ammonia. This excellent fertiliser is of the greatest worth to our agricultural community in the endeavour to produce more. There is an eager market for it abroad, and the national position demands that our export trade shall be swelled to its fullest limits. Then there is benzol, a highly efficient, home-produced motor spirit, that saves the import of petrol, and assists in solving the great transport question which is of vital importance to the improvement of production. At present only about 14 per cent. of our coal is carbonised, and benzol extracted. Again, decrease in the use of coal in its raw state, and an increase in the quantity carbonised, would provide us with more heavy oil for generating power to drive our naval and merchant ships, and save importation. Then consider the dye industry, for the products of which we have been very largely, and all too long, dependent on other countries. The distillation of coal tar gives us the materials for the quantities of dyes we need. The "key" industry must be fostered. Then, of course, there is the gas coke, of great value as a cleanly, efficient, and smokeless fuel, suitable for domestic and many factory uses, especially for steam-raising. We have seen lately how large economies have been effected at the East Greenwich Electric Power Station of the London County Council by using coke and coal under the boiler on the "Sandwich" system; and in the latest installation at the Manchester Corporation Electricity Works the same system has been adopted. Apart from the direct money economy, a high evaporative duty is secured, by the intensity of the combustion of the fuel due to the porosity given to the bed by the use of coke.

In our striving after greater production and national economy, it is essential that the facts I have stated should take a foremost place. Our prosperity has been founded on an ample supply of cheap, readily available coal; but we have been too prodigal in its use. The most economical expenditure of our stock as yet unmined is a matter of vital national concern. If Great Britain ever has to begin to import coal, then, in the words of Lord Moulton, "the end of our industrial and commercial greatness

will not be far distant." We must cease the waste of coal, and learn to use it wisely and well. Every smoking chimney, domestic or factory, spells waste of coal, and the dissipation of those chemical by-products the recovery of which would be of such inestimable gain to the nation. In addition, every smoking chimney pouring forth its wasted energy, pollutes the atmosphere, obstructs the sunshine, poisons our lungs, and lowers our physical fitness. Destruction is the antithesis of production, and any effort that can abate the smoke nuisance will be a direct contribution to our national effort to improve our economic position. This is not a matter of minor importance, or a side issue. Our large cities pay a heavy tribute year by year through the continuance of this evil. After the most exhaustive investigations, Manchester has come to the conclusion that the damage wrought by smoke, and the increased cost incurred owing to its unwelcome presence, is at least £1 per head per annum, or £750,000 for the city. The national case for the extended use of gas is overwhelming. The commodity we are considering this afternoon has played a great part in the life of this country, and is destined to take a still more prominent place in the future. Gas manufacturing is one of our greatest industries; no industry has ever been developed which has been of more service to the community. Quoting from figures presented lately by Mr. D. Milne Watson, the Governor at the Gas Light and Coke Co., to the Board of Trade, it has 150 millions of capital invested in it; it employs some 100,000 workers; there are 1,600 gas undertakings. It uses 20 million tons of coal yearly, and some 50 million gallons of gas oil. There are over 8,000,000 consumers of gas, and nearly 3,000 trades in which gas is used in varying ways. It has been one of the greatest contributors to the nation's health, comfort, efficiency and well-being; and I am convinced that in the search for means for providing the larger output of which the nation stands in such need to-day we must look to gas as one of the chief agents.

This being so, may I, in conclusion, say a few words which I hope will reach the eyes of many members of our Legislature? The Government has been considering the question of coal conservation, and of the provision of power. But it has been doing this from a single standpoint, and along a single line, with the result that special legislation has been passed for the electricity industry. Had the Government considered the matter exhaustively from all points of view, it would have been seen that the provision of power cannot be, if industrial economy is to be served to the utmost, the monopoly of any one agent. It would also have seen that the efficient supply of a heating agent is as important in industrial economy and the conservation of coal, as the supply of a power agent. I am sorry to say, but it is the truth, that the Government has been in this matter inexcusably short-sighted, as I think, my paper will have shown. Fortunately the Fuel Research Board has made a report upon which it is hoped legislation will be passed this session which will help the gas industry to render greater service to communities and industries. It is the duty of all members of your influential Society to urge upon their Members of Parliament that this should be done, and not only this, but that there should be revision of the statutory enactments relating to the capital of the same industry, so that capital may obtain a fair return for the service it renders, which it is not now doing—principally through the terms of the sliding scale of prices and dividends (which were determined on pre-war conditions) being out of harmony with what we must now accept as the newly established economic position. On the grounds alike of justice and progress, and to enable the industry to provide for the increasing demand for gas for manufacturing purposes, a modification of enactments is called for, and I hope the call will not be made in vain.

Finally, I wish to express my thanks to many engineering friends who have responded to my request for information on the subject treated in this paper, and to Brayshaw Furnaces and Tools, Ltd., The Davis Furnace Company (Luton), Fletcher, Russell and Company (Warrington), The Nautilus Fire Company (London), The Richmond Gas Stove and Meter Company (Warrington), John Wright and Company (Birmingham), for details of their appliances, photographs, and drawings.

DISCUSSION.

MR. D. MILNE WATSON said he had listened to the paper with the greatest interest. The author had put the case for gas, especially in connection with furnace work, in a most clear and able manner, and the slides he had shown had been excellent. He only wished that the author had not been speaking to a body of ladies and gentlemen who were probably all converted to the importance of gas, but that Sir Auckland Geddes and a few other people had been present. He

was sure the paper would have done a great deal to convince them that gas had to be reckoned with in any scheme of future development in this country. He thought the figures the author gave with regard to the economy of using gas instead of solid fuel should be spread broadcast throughout the country. Probably there were not very many people who realised the enormous economy that could be effected by using gas for furnace work, and he hoped that publicity would be given to the figures in the paper. Such papers were exceedingly interesting to those who were connected with the gas industry, because, however much they might be immersed in gas affairs, there was always a great deal to be learned from an expert like the author, and they realised what a great industry they had the honour to serve. At the same time, however, it was much more important that the information which had been so clearly and ably given in the paper should get into the heads of people who really knew nothing about the subject and were imbued with the idea that electricity was capable of doing everything and that gas was almost out of date. He was glad to say that recently people all over the country, and especially the people who counted in such matters, had begun to realise that that was not so, and that by the use of gas a great economy of the national coal resources was going to be achieved. He had very good reason for believing that the report of Sir Dugald Clerk and Professor Smithells did arouse the Government Departments that were concerned with the matter and made them feel that perhaps they were backing the wrong horse in backing electricity. Those who were concerned with the gas industry must keep on insisting on that, because if they did not save themselves nobody else would come forward to help them. They felt sure that the facts would ultimately triumph, but still there was so much error and wrong thinking abroad in the land at the present time that they should lose no possible opportunity of seeing that people were enlightened on the subject.

Mr. F. W. Goodenough said the paper was full of valuable facts and not merely opinions, and he could assure Mr. Milne Watson that every effort would be made to see that those facts were spread broadcast. The difficulty was to get people to read the publications that were sent to them, but every step would certainly be taken to see that those who ought to know the facts were made acquainted with them. The figures given in the paper were very striking, and some of them came almost as a surprise even to those who were closely connected with the gas industry; they hardly knew how very strong their case was. The author had stated in his paper that he could not deal with all branches of industry, but other people could say from their experience in trades other than those with which the author dealt that the same results had been found with regard to the increase of output per foot of factory, per hand employed, and per pound of capital expended, by the use of gas. The facts in the paper spoke for themselves and required very little comment or criticism, and he would therefore conclude his remarks by joining with Mr. Milne Watson in expressing his appreciation of the paper.

The Chairman (Sir Robert A. Hadfield), in moving a hearty vote of thanks to the author for his very able paper, said the author had put forward the facts in a very lucid and interesting manner. He considered it so valuable that he intended to distribute a number of copies of the paper to the staff in the laboratory of his own works. The author had rightly laid stress on the importance of temperature. One might heat a bar of steel to, say, 728° C., then quench in water and it would be soft; but, if one took the same piece of steel and heated it to only 2° or 3° more and then quenched it in water, there was obtained that wonderful product, hardened steel.

The resolution of thanks was carried unanimously.

The Author, in reply, said he hoped the paper would reach a larger audience when it was printed, and if it caused gas to be used in greater quantities for all purposes of production and thus increased the wealth of the nation he would feel amply repaid for any trouble he might have taken in preparing the paper.

The meeting then terminated.

GENERAL NOTES.

Ideal Homes Exhibition in Holland.—An ideal homes exhibition is to be held at Amsterdam from May 1st to June 7th. The promoters are the Nederlandsche Vereeniging Van Hursvrouwen (Afd. Amsterdam), and their aim is described as the demonstration of everything of a simple and economical nature that contributes to decorating and beautifying houses and homes. It is assumed that the exhibition will attract British manufacturers of furniture and allied products. The total space at disposal for actual exhibition purposes is 4,000 square metres.

Post-war German Imports.—The President of the Board of Trade, Sir Robert Horne, replying to a question in Parliament on April 12th, said that the imports into the United Kingdom during the past six months of goods consigned from Germany and classed in the trade returns of this country as wholly or partially manufactured were valued at £2,432,202. So far as he knew the German Government does not levy any export tax. The question of the benefit from the depreciation of the exchange rate of the mark depended on the terms of purchase, for example, whether payment was stipulated for in sterling or in marks.

Corrections.—In the *Journal* of April 9th, p. 336, col. 1, sixteen lines from the bottom, the date 1459 should be 1450; and in col. 2, six lines from the top, the date 1664 should be 1644.

Journal of the Royal Society of Arts.

No. 3,518. VOL. LXVIII.

FRIDAY, APRIL 23, 1920.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

MONDAY, APRIL 26th, at 8 p.m. (Cantor Lecture.) WALTER ROSENHAIN, B.A., D.Sc., F.R.S., Superintendent, Department of Metallurgy and Metallurgical Chemistry, National Physical Laboratory, "Aluminium and its Alloys." (Lecture III.)

WEDNESDAY, APRIL 28th, at 4.30 p.m. (Ordinary Meeting.) BRIGADIER-GENERAL CHARLES H. SHERRILL, LL.D., "Ancient Stained Glass." THE RIGHT HON. LORD DESBOROUGH, K.C.V.O., will preside.

CANTOR LECTURE.

On Monday evening, April 19th, DR. WALTER ROSENHAIN, F.R.S., delivered the second lecture of his course on "Aluminium and its Alloys."

The lectures will be published in the *Journal* during the summer recess.

SEVENTEENTH ORDINARY MEETING.

WEDNESDAY, APRIL 21st; THE MARQUESS OF LONDONDERRY, K.G., M.V.O., Under-Secretary of State for Air, in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Birrell, William, Loughborough.
Dobbs, Ernest John, Birmingham.
Walker, W. Ralph, J.P., Lochgilphead, Argyll.

The following candidates were balloted for and duly elected Fellows of the Society:—

Bellamy, F. S., Teneriffe, Canary Islands.
Board of Trade, Great George-street, S.W. 1.
Cleghorn, Miss Maude Lina West, F.L.S., Calcutta, India.
Colvin, Sir Elliot Graham, K.C.S.I., London.
Durham, The Right Hon. the Earl of, K.G., G.C.V.O., London.
Green, Frank Ernest, Uxbridge.
Griffith, John Henry, Llanbedr, Merioneth.
Jones-Keith, W., Rouen, France.
Keller, Miss Frances A., New York City, U.S.A.
Mutch, Stanley Robert, M.A., London.
Osborne, Charles Haddon, J.P., Luton.
Pole, Major D. Graham, London.
Randell, Charles Edmund, London.
Sankey, Charles Herbert, Chislehurst, Kent.
Sutherland, Daniel Manson, Teddington.
Taylor, John Brown, Dundee.
Wren, Captain Frederick, M.G.C., Bedford.

A paper on "The Commercial Future of Airships" was read by AIR-COMMODORE EDWARD MAITLAND, C.M.G., D.S.O., A.F.C.

The paper and discussion will be published in a subsequent number of the *Journal*.

PROCEEDINGS OF THE SOCIETY.

FOURTEENTH ORDINARY MEETING.

WEDNESDAY, MARCH 17th; MR. WILLIAM KENNEDY JONES, M.P., Chairman of the Advisory Committee on London Traffic, in the chair.

THE CHAIRMAN, in introducing the author, expressed his pleasure at seeing so large an audience present prepared to take an interest in the problem of London traffic, a problem which affected every single one of the millions of this city, and which was now assuming a very acute form. He also conceived it to be his duty to express the pleasure of the audience at having the opportunity of listening to Mr. Worby Beaumont, a leading engineering expert on street traffic traction, and a gentleman, if he might say so, who had grown up with the motor industry. He (the Chairman) seemed to recollect that Mr. Beaumont was a pioneer even in the days when a

man with a red flag had to walk before a motor-car just as though it were a traction engine. He understood that the great charm of the papers read before the Royal Society of Arts was that there was freedom of speech; the author could advance any views he pleased, and when he had finished the audience could arise and demolish those sentiments. He anticipated something of that kind would happen at the present meeting, but as Chairman of the meeting he had to act impartially as referee, and in that capacity he would endeavour to do his best.

The paper read was --

STREET PASSENGER TRANSPORT OF LONDON.

By William Worby Beaumont, M.Inst.C.E.

Few things are more widely on exhibition for public observation than the methods and means of passenger transit of London and its suburbs.

Insufficiency forces itself into recognition, and defects are superficially observed and often wrongly interpreted. Hence a marked feature of the prevalent discussion concerning London passenger transport is the contrariety of opinion expressed and the consequent delay of unanimity of action. To some extent this delay is due to partisan element which enters into discussions, writings and conclusions of those who speak from the technical points of view for those who are concerned with the one or the other of the present systems and means of transport.

Some usefulness may therefore attach to a discussion of the arguments that are most commonly the cause of the fissiparous misdirection of public opinion and of the inconclusiveness of the proposals often made by those concerned in the present modes of conveyance.

There are but two systems of conveyance of passengers on the streets and roads of London which have to be considered with regard to their present and their probable future.

These are the street railways or tramways and the mechanically propelled omnibuses. All the other kinds of vehicles that are in use have only to be mentioned as things that get in the way of tramcars or have to be avoided by the omnibuses.

As a city with the largest population in the world, it requires the most comprehensive and efficient means of passenger transport ever called for.

Although the number of yearly journeys per head of the vast urban and suburban population of this great city—now about eight millions—had in a few cases been exceeded in some smaller cities, the total number has now by all modes of locomotion—rail, tram and bus—reached 393, and the number of passengers carried is the greatest ever known, and no mere statement of the numbers carried conveys any adequate idea of the bigness of the transport problem.

The figures available purport to show that in 1918, 198,334,499 passengers were carried by the tramcars and 652,562,327 by the omnibuses of the Electric Railway tram and omnibus group. The omnibus mileage for the year 1918 was 73,152,709 miles.

In 1918 the tramcars of the Underground group carried 164,159,233 passengers and the omnibuses 710,192,568. This last rose to 718,723,849 in 1914, but the omnibuses taken away for foreign war service in that year reduced the total in the following year to 655,333,017, a reduction of 63,390,830, and the tramcar passengers decreased in the same time by 1,521,433.

In 1913 the tramcars of the London County Council ran nearly 54,000,000 miles and carried about 512,652,653 passengers, and although this number decreased in 1914–15 it has steadily risen since then, and in the year ended March 31st, 1917, the number carried was 586,127,976, and in the year 1918 it was 636,157,431 and the car mileage was 49,189,866.

These figures are given merely to show how gigantic the surface passenger transport now is. The figures at the same time show the relative patronage by the public of the two systems.

Of tramways there are in the Metropolitan area about 348 route miles.

Those of the London County Council consist of 141·67 route miles, 121·89 of which are constructed on the conduit system, only 19·77 miles being on the overhead system.

The conduit system costs approximately £89,000 per mile, and the overhead about £50,000 per mile.

The figures showing the number of passengers carried by the tramways and the omnibuses are so differently stated by those who have given evidence, as in the recent inquiry before the Select Committee on London Traffic, that it is not possible to assert with certainty a nearly exact number.

The figures which are given, however, are sufficient to show how vast in numbers is the total in numbers of millions for whom provision has to be made, and the relative numbers carried by the two methods of transport.

The important question then is: How is

transport provision to be best made, not simply now but in the near future for carrying these millions, what vehicles are best and likely to be best for this present and for the future traffic?

At present the street transport accommodation provided consists of approximately:—

	Approx.
Tramcars and trailers held by the London County Council . . .	1,800
Omnibuses, London General Omnibus Company	2,550
Seats by Tramcars	136,800
Seats by Omnibuses	86,700

More accommodation is required to meet the present demand, even if the Metropolitan extension railway lines and stations, and the South-Western service to Ludgate-Hill, were again opened for traffic.

The London County Council is seeking powers not simply for additional cars, but for large extensions of tramway track. Some of these are extensions outside the areas at present served, but most are within what may be called the "inner" London area.

The omnibus companies are also increasing the number of omnibuses on the whole of their service routes, and are introducing an omnibus to carry 46 passengers instead of 34.

The London County Council had proposed to construct about 90 miles of new track at a cost of about £5,500,000 for track and equipment, and about £2,500,000 for street alterations to meet tramway space requirements. It has, however, now, it is understood, concluded that it is important in the opinion of the Council to proceed immediately with the construction of only 43 miles of single track. This, it is estimated will cost, including cars, cables, and street alterations, about £4,200,000, or about £97,630 per mile of single track.

If the schemes under this proposal were carried out, it would make the total length of the London County Council single track about 183·67 miles. The schemes include—

London County Council Proposed Tramway Extensions.

Description.	Length in terms of single line of track.			System of traction proposed.	Constructional cost per mile of single track.	Total cost, including acquisition of land and works for street widening.
	M.	F.	Ch.		£	£
1. Charles Street to Blackfriars Bridge . . .	1	3	3	Conduit	88,282	124,665
2. Gray's Inn Road to Farringdon Road . .	0	5	6	,,	106,714	75,750

13. Tooley Street terminus to Hop Exchange .	0	4	6	,,	67,358	38,740
14. Waterloo Road to Blackfriars Road, *viâ* the New Cut.	0	4	4	,,	83,218	45,770
15. High Street, Wandsworth, to Roehampton Lane.	4	2	1	Conduit and overhead	38,526	357,220
16. Forest Hill to Crystal Palace	3	1	6	,,	46,808	209,285
17. West Norwood to Crystal Palace	3	7	8	Overhead	45,111	193,170
						£3,960,245
Spare cars, cables, etc.						245,100
						£4,205,345

It would appear from these figures of cost, which are extremely high, that the Council has some conception of the greater cost of construction in the busy thoroughfares of London as compared with that at any other time or in any other city in the Kingdom.

The conduit system is apparently to cost anything from nearly seventy thousand to nearly one hundred and fifty thousand pounds per mile of single track. Where a combination of conduit and overhead works is to be used, the average cost reaches about an average of

£58,537. On the one line on which overhead equipment is to be used the cost is estimated at £45,111 per mile of single track.

Among the seventeen lines included in these schemes, there are three on both conduit and overhead systems to be used, on which the change from plough to trolley-rod must be made during the journeys. These include the proposed line from Marble Arch to Cricklewood at a cost of £850,000, the Shepherd's Bush to Marble Arch at a cost of £393,000, and the Wandsworth to Roehampton Lane at a cost of £357,000.

There are two proposed lines between Victoria and Westminster Bridge, together 8 miles and 1 furlong and $\frac{1}{5}$ chain, which are estimated to cost over £359,000.

The London County Council tramways at present include, as above mentioned, 141·67 route miles, of which 121·89 miles are constructed on the conduit system.

In 1914 there were 1,452 cars used in working the London County Council system, or about 10 cars per street mile of track. In August, 1919, there were 1,210 cars and 112 trailers in use, and there are now about between 1,300 and 1,400 cars and trailers in use.

In the year ended March 31st, 1918, the total car mileage was 49,189,866, and the total number of passengers carried was 636,157,431. Hence the average number of passengers carried per car mile was 12·93.

The proposed new extensions, if carried out, would add to the car mileage, but it may be questioned whether the passengers carried per car mile would approach even that of the present lines.

The tramways of the companies and of the authorities, other than the London County Council, carried passengers in the year 1918 as follows:—

Electric Railway, tramway and omnibus group	198,334,499
Various London and Suburban authorities and companies .	157,398,343
Omnibuses in the year 1918, not including the "National," covered . . . . . miles	73,152,709
and carried passengers, 1918 . .	652,562,327
or, per omnibus mile, 1918 . .	8·93

Thus the number of passengers carried in Greater London during that year reached the colossal total of 1,644,452,600.

The omnibuses thus carried over two-thirds of the number carried by *all* the tramways, and 1·025 times the number carried by the London County Council tramcars.

For the future, then, the question arises: "What shall be the means of transport—the tramway and tramcar, tramcar and trailer, or the motor omnibus?"

It used to be—and with reason—said that the low resistance to traction on rails was a sufficient reason for the preference of the tramcar as compared with any then usual forms of road passenger conveyance.

This argument was good so long as public-service vehicles were all horse-hauled, or even for some time after the advent of the electric tramcar; but it ceased to be of any value about twelve years ago, when the light internal-combustion engine and modern mechanical design and materials, including good solid rubber tyres, had made the motor omnibus a tried, practical and commercial success.

It has become obvious that the relative carrying power of the tramcar and the omnibus cannot be represented by the number of seats of the two vehicles.

The tramcar has 76 seats and the omnibus 34,* or 2·3 to 1·0. From this comparison, it would appear that the tramcar should carry more than twice the omnibus: but the traffic figures show that the omnibus actually carries more passengers per seat than the tramcar, in the proportion 0·263 per bus seat to 0·17 per car seat.

This is a result of a number of differences in the character and appropriateness of the two kinds of vehicle for the work to be done and the streets and roads in which it has to be done.

In a paper recently read before the Institution of Civil Engineers, Mr. H. H. Gordon said: "There has been little premeditated effort to fit either the vehicles to the roads or the roads to the vehicles they are to accommodate." This, judging by its success, in contradicted by the omnibus, and it must be admitted that "premeditated effort" has successfully made great strides in the last dozen years toward fitting the roads of London to the requirements of the vehicles they are to carry. It may be urged, in fact, that one of the chief reasons for the success of the omnibus is its fitness for the conditions imposed by the roads, their other users, and by the public who want to ride on them.

It must be remembered that street vehicle transport does not consist simply in carrying.

* This will, in the near future, be rapidly increased to 40 or 46 seats, and the relative seating capacity of tramcar to bus reduced from 2·3 to 1·65.

Every kind of vehicle must stop somewhere to take up what it is to carry, and somewhere to put it down. Trading vehicles have to take up, and to stop for, delivery at shops and warehouses. The passenger vehicle which most fully accommodates itself and the passenger is that which can take him up with least inconvenience and danger, and can permit other vehicles to stop at shop and warehouse without itself being stopped. Thus it requires, and supplies, a freedom of movement which is only possible by dirigibility.

There is no validity in a complaint that frontagers use the streets as collecting and stopping places for the vehicles they employ, or that passenger vehicles stop at shop fronts. Were it not for the shops and various kinds of business places with street frontages, there would be no passengers through the great majority of them, and no reason for tramcars or motorbuses. That being the case the vehicles for passenger transport can seldom "keep in line" as Mr. Gordon wishes, and they would be the causes of the most aggravating obstruction if they did.

Within the areas of a conglomeration of cities like those which make up London, the variety and vast quantity of traffic—greater and of more variety than in any other place in the world—demand the greatest flexibility of movement for all vehicles, and this being so, the tramcar cannot, in the areas of greatest traffic of any of the kinds, meet the conditions as well as the dirigible vehicle.

It is not alone the published statistics showing the passenger carrying capabilities of the tramcar and the numbers, which indicate a choice as to selection of public - service passenger street transport.

So far as mere numbers carried per seat per vehicle mile, the public preference is plainly for the motorbus. This preference does not seem likely to be transferred to the tramcar as a consequence of any extensions of miles of route or of coupling up of existing lines.

What then is the cause of this preference by a public which does not concern itself with any of the questions of capital outlay or of relation between receipts and working costs which are the burden on those who supply the means of transit? What is the cause of the preference and of the success of which Sir H. Haward, the Controller of the London County Council complains, when he says that if there were less competition with motorbuses, the London County Council tramway undertaking could probably meet expenses on the present fares? This he says although the tramcars take all they can carry in the crush hours.

The answer to all this is the one word, convenience. The omnibus takes up its passengers from the kerb, just as the railway passenger is taken up from the platform of the privately owned station.

The omnibus with a slower maximum speed gives a higher average speed, although at a recent meeting of the London County Council the chairman of the highways committee stated that the average speed of the Council's cars was higher than that of the cars of any other city in the Kingdom.

The omnibus can and does ply with success and convenience to passengers through streets and round corners of narrow streets through which the tramcar could not pass.

The omnibus carries its passengers to busy streets in which no tramway could be laid.

Even to destinations to which there is no through route, the omnibus passenger can change at the kerb from one bus to another.

The full omnibus need not wait while one in front is filling or unloading, and one which will go south is not kept by two in front, one of which is in a mile, perhaps, turning east, and the other turning west off the same pair of rails, as for instance at either Blackfriars or Westminster.

The omnibus passenger knows that, even though it is possible, though seldom of occurrence, that his omnibus may develop some defect which may cause stoppage and a short wait for the next bus, he will not be subject to the long waits which attend the stoppage of from a few to a half mile of tramcars owing to a break-down of one car or of some vehicle on the rails.

These are some of the causes of public preference for the omnibus.

From the future utility and financial points of view, there are others of equal or greater importance which tell in favour of the omnibus, and appeal to the whole community and not simply to the tramcar or omnibus passenger *per se*.

The first of these is the fact that the omnibus runs upon the common highway, and although it can run on any road (witness the present condition of the neglected many), good roads suit it and its passengers better. This fact encourages the making and maintenance of good roads, because what is desirable by the omnibus is wanted by all the other multifarious users.

A second is that the tramways are the cause of very great delay all day long to the ordinary user of the road. They are also the cause of great numbers of accidents to vehicles and users of the highway, especially with the track in the condition it is in many places now. These causes must mean, with time and labour at their present value, thousands of pounds sterling losses per day.

A third is that the repairs to the tramway track are the constant cause of breaking up the road surface for small short-length repairs or long length replacements.

A fourth is that where tramway rails exist the continuity of the road surface is broken.

With the overhead system, two lines, the road is broken up into five rail separated sections with eight jointings between rails and paving.

With the conduit system it is broken up into seven sections with no less than twelve jointings between rails and paving.

It thus becomes exceedingly difficult to maintain a good road surface where the road is cut up into all these sections and many joints, and the continuity of surface so completely broken.

In many places the roadway is broken up into so many pieces that the proper paving material is only a sort of mosaic in the interstices of a steel rail network. One of the worst places is, for example, that at the Elephant and Castle and thereabout; but there are many others, as at Camberwell Green, St. George's Circus, and Finsbury and Islington. In some such places repair work is unending.

The statement has been many times made during the past few years that in the streets and roads, the tramcars use only the rails upon which they run. This statement has been made so many times by those interested, that they appear now to think it is true. It is, of course, as far from the truth as the finite is from the infinite. Yet the London County Council is now seeking powers that shall relieve the Council from the liability for the maintenance of the roadway in streets "in which tramways are or may hereafter be worked, with the exception of any rails or other works which may be used for the purpose of the tramway."

This demand is itself so regardless of the facts that it forms a proof of the incapability of the tramway system to meet its own trading costs.

Independent observers know that there are many parts of the road paving along the tram rails where the rails have worn down faster than even wood-paving setts, and the edges of the setts have actually been cut away, not worn by the ordinary vehicular traffic, but cut away by tramway workmen to allow the passage of the car wheels and to allow the track brake blocks to get down to the rails. In some places the corners of the granite or basalt setts have similarly been worn away by the passage of the car wheels and brake blocks. The road paving has everywhere to be broken up and re-laid alongside the rails, not because of the roadway requirements, but because of the rail and tramcar requirements. In some parts there are miles of road in which there are inspection holes and covers between the rails at every fourteen or fifteen feet, and in others inspection holes and covers in the space between the tracks forming complete user of the whole roadway. Yet the London County Council would ask the local authorities to pay for this part of their maintenance expenses.

A fifth reason is the uneasy feeling caused by the growing deficiency on the working of the tramways and the knowledge that a large part of the whole of the track system is in need of renewals which will cost an enormous sum. Sir H. Haward recently stated that the deficiency on the working of the London County Council tramways was at present (December 1919) £137,000, and that the estimated deficiency for the year 1920–21 would be £760,000.

With regard to these and other causes of suspicion in the eyes of those who are free to take a detached view of the tramway question, there are several matters of fact which affect their conclusions. The first is that obsolescence and cost of maintenance are dictating the fate of the obsolete. The tram rails they look upon as an anachronism for the streets of London, however appropriate they may be in Glasgow or in Buenos Ayres, and they hear of the tramway crisis in the United States.

They look at the leviathan London County Council tramcars weighing fifteen tons, or with seventy-six passengers nearly twenty tons, and compare this weight with that of other vehicles that are up-to-date, the motorbus for example, which they see is the lightest vehicle on the road per passenger carried. They compare the following figures:—

COMPARATIVE WEIGHTS OF THE TRAMCAR AND OF THE MOTORBUS PER PASSENGER CARRIED.

	Tramcar. cwts.	Omnibus. cwts.
With full load including driver and conductor	4·0	2·14
Half load	8·0	4·22
Quarter load	16·0	8·56
With seven passengers . . .	43·5	10·40

With such a dead load it is plain, even to the man in the street, that the tramcar labours under enormous disadvantages, even though the traction resistance on rails is less than that of solid rubber tyres on most common road surfaces.

This apparent advantage as to traction is, however, not to be seen in the power required by the tramcar.

The tramcar seating is 2·3 times that of the omnibus, but the passengers carried are not in anything like that proportion. The traffic returns, in fact, show that while the average of passengers carried has, as before stated, been only 12·9 per car mile (12 passengers to 15 tons of car, or 1·25 tons per passenger), the omnibuses carried 8·93 passengers per bus mile (8·93 passengers to 3·6 tons of omnibus, or 0·44 ton per passenger). Yet although the omnibus has only one engine of about 40 horse-power, the tramcar is fitted with two 40 horse-power motors each capable of about 100 per cent. overload, making a total available of 160 horse-power or four times that necessary with the omnibus. The tramcar thus requires 1·73 times or nearly twice the power per passenger seat that is required by the motor omnibus, or more than twice the power per passenger carried. A large proportion of this power is only required for the purposes of rapid acceleration of the heavy car, the high speed between stopping places now so generally used being easily maintained once the speed is reached. This high speed is one of the chief causes of the rapid deterioration of the permanent way and of the great cost of permanent way renewals and adjoining roadway.

So great is the wear caused by the powerful track brakes, which are a necessity with the high speeds, and are severely used at every stop, that the treads of the rails, as above mentioned, wear down much faster than the adjacent wood or granite paving. The result is not only damage to the road surface and the production of tram rail channels dangerous for most, if not all, the other users of the roads, but great cost to the London County Council for the cutting away of the rail cheek.

Only recently the Council entered into a contract with a firm for the removal by cutting away the high cheeks of 50 miles of single track rails at a cost of £14,500.

In many places tram rails are laid where very short radius curves are a necessity if the tramway is to be laid at all. At these places the wear of the rails, and especially the sides of the grooves, is enormous, and the car wheels suffer in acting as very blunt milling cutters under enormous pressures.

On all parts of the system the rails are subject to destructive rolling pressures by the small wheels of the heavy cars. This pressure on the whole area of contact of the pony wheels reaches 31·8 tons as a static pressure, and not less than 50 tons per square inch on the central part of the contact. With cars at ordinary speeds this pressure probably reaches at least 90 tons, and when at speed on long radius curves with the car heeling over so that the greater part of the load rests on the wheels on the outside rail of the curve it may considerably exceed 100 tons per square inch. The rapid destruction of the surface of the rails is the inevitable result.

Tramway constructing and working does not, especially in the greater part of London, permit of the adoption of modern engineering practice in many respects.

A great deal of tramway practice of to-day discredits modern mechanical engineering practice and science.

This is not the fault of the engineers and managers who are responsible for the present conduct of the tramways operation and maintenance. They have to do the best that is possible with an inherited system of construction and working, now an anachronism, and the wonder is that they succeed so well, though at a stupendous cost which is not their fault and would be greater but for their skill.

It may be asked, what are the causes of the grave defects which are summed up in these criticisms. They may be briefly catalogued as follows :—

1. The existence of the rails.
2. The use of very heavy cars.
3. The use of very heavy cars running on small wheels.
4. The very high speeds permitted.
5. The common use of magnetic track brakes rendered necessary and destructive of the rails by the high speeds between short distance stops.
6. The use of short-radius curves.
7. The destructive grinding of rails and wheels on short-radius curves.
8. The rigid fixture of both wheels on each axle causing most of the destructive grinding of wheel and rail and breakage of axles.
9. The use of a design and construction and working of cars which render the use of splendid material (manganese steel) in parts of the

permanent way only a palliative of the rapid destruction.

10. The use of a design and construction of car which ignores and makes impossible the advantageous use of modern mechanical engineering knowledge and experience in lightness of structure, high strength materials, and high efficiency mechanism.

On each of these points some further remarks must be made:—

Concerning 1.—The existence of the rails is the cause of the break of continuity of the road surface and bed, and of the cost of the contiguous road repairs. The fixity of the rails, the path of the tramcar, is the cause of the arrogation of a car in a crush and the origin of obstruction and congestion.

Concerning 2.—The use of very heavy cars is the cause of unnecessary high cost of working and high cost of maintenance of its axles, its wheels and tyres, its track brakes and its operating mechanism in spite of its possession of electric motors which cannot be too highly praised as fine pieces of up-to-date mechanism.

Concerning 3.—The use of the small wheels of tramcars and the consequent excessive pressure per unit of surface contact on the rails, causes the elastic limit of extension of the steel at the point of maximum intensity of pressure to be exceeded. Hence, by a process as I have elsewhere explained, the origin and production of corrugation. This is the cause of another large item of expenditure. It is also the cause of excessive noise and of annoyances to people in houses along the tramway route.

Concerning 4.—The very high speeds make it necessary to put the brakes on while the car is still at a high speed in order that the time occupied at stopping places shall be as short as possible and so that an average speed comparable with that of other vehicles can be maintained. To attain this high speed between stops the high power and big current consumption for rapid re-acceleration after each stop are required.

Concerning 5.—This use of the brakes is a great cause of the rapid wear of the rail treads and of leaving the check standing up high above the tread. It results in the necessary waste of rail material by fusing off or cutting away the check by the special appliances referred to, or breaking it off by sledge hammers as is often done. It also results in serrated and knife-like edges which cut every rubber tyre that passes over them, and in a condition of the permanent way which is a source of accident to other vehicles and cycles, and of losses daily which in £ *s. d.* it is difficult to estimate.

Concerning 6.—The use of short-radius curves is dictated by the desire to lay lines in situations which are unsatisfactory for railway purposes. The obvious mechanical unfitness is defied, and the consequence is that a barbarous use is made of costly materials which would make engineers in any other branch of engineering admit the inadequacy of language.

Concerning 7.—The use of tramcar wheel flanges as crude milling cutters for irregular shaping out of rail grooves is as costly as it is barbarous. Examination of these grubbed-out grooves and sides of checks shows how the alternating rise and fall of the wheels in their efforts to leave the grooves carves them out, and an examiner may wonder that the cars do not more often jump the track than they do.

Concerning 8.—Except on railways where the wheels used are large and where there are no small-radius curves comparable with the small curves on tramways, there are nowhere heavily loaded pairs of wheels rigidly fixed to the ends of an axle. Every time a tramcar passes over a quarter circle of, say, 50 ft. inner rail curve radius, the wheels have a difference of length of path of 3 ft. 9 in. The axles have to carry the torsional stress of twisting the wheels over this distance forcing the wheels under their heavy load to slide and grub and grind over the rails instead of rolling over them.

Concerning 9.—The enormous weight and power of the cars on small wheels at points, crossings and curves, is the cause of cutting, grinding and rolling wear, so rapid of even the tough and hard materials used, that in any other branch of engineering such wear, tear and waste would be admitted a more than sufficient proof that an entire change is necessary.

Concerning 10.—The cars at present employed seem to be built on the principle that excessive weight in every part is of no harm and is required for frictional adhesion on the rails.. Whatever the cause the great weight is recognised by Mr. A. L. C. Fell, the engineer of the London County Council tramways, as he recently said cars of lighter weight were desirable As a vehicle for carrying passengers for street traffic it is of excessive weight in almost the whole of its steel work, its framing, its under and running gear, and in the whole of its body work. Added to this is the excessive weight of scantling of the covered top, from the proportions of which it might be thought that several

tons of something were to be carried on the roof, when in reality its duty is only that of a good umbrella.

In conclusion then as to what is to be done in the future.

1. We see that the cost of running the present system of heavy tramcars, especially on a conduit system a few years after installation, does not pay.

2. We see that the carrying capacity in actual practice of tramcar and of omnibus is not directly in proportion to the seating capacity.

3. We see that the greater convenience of the omnibus, taking up its passengers at the kerb and free to move off as loaded independently of others in front and independent of rails, can, and does, carry one and a half times the passengers per seat mile carried by the tramcar.

4. We know that if omnibuses were in service they would run on the sides of the road and accommodate themselves to all other users of the road and run in accordance with its rules and usages, instead of monopolising the whole of a roadway as the tramway does in effect in most streets and does actually on the Victoria Embankment, or causing confusion and obstruction as it does in nearly all busy thoroughfares.

5. Judging by the proved capacity of the omnibus in passengers per mile, its proved rapidity of loading up and celerity of dispatch, it is now evident that an increase in the number of omnibuses of perhaps slightly more than the present number of tramcars would make the tramways and tramcars as unnecessary as they proved to be in the Liverpool Road, Islington.

6. The question of cost of the removal of the tramways, and restoration of the highways to their proper condition for all purposes need not perhaps be now considered. The London County Council could sell the cars as they have sold a considerable number for use in towns where tramways are of more suitable employment than they can possibly be in London. The rails and plant could probably be sold for a great deal more than the cost of reinstatement of the roadways.

7. It is probable that the vast number of traders in London, whose vehicular repairing costs and drivers and attendants' time costs would be so much lessened by the absence of all tramways and tramcars, would find a plump subscription for provision of a redemption fund, and for paying the difference between the receipts from the sale of the whole of the tramway materials and equipment, and the cost of the reinstatement of the roadways, a profitable investment.

It is to be regretted that this conclusion follows on the facts herein dwelt upon, but it is a conclusion which in some other fields has similarly had to be faced as a result of entrance upon a trading enterprise, the foundations of which have become obsolete. However, "What cannot be avoided 'twere childish weakness to lament or fear."—3. *Henry VI.*

DISCUSSION.

THE CHAIRMAN (Mr. Kennedy Jones, M.P.) said he was sure the audience would agree with him when he said that they had listened to a careful, interesting, informative, and, he might add, a provocative paper, which was likely to produce a great deal of criticism and comment.

MR. H. H. GORDON, J.P. (L.C.C. and Member of the Technical Committee on London Traffic), said there were certain points on which he was in complete agreement with the author, and when Mr. Beaumont called attention to the many structural points of engineering practice as applied to tramcars, he had good grounds for the criticisms which he had made. For instance, when Mr. Beaumont criticised the excess of weights and the frequent misapplication of good material, he (Mr. Gordon) fully agreed with him. But those, after all, were matters of detail, and ones which could be cured in the next tramcar built. Far more important—and he ventured to submit it was the only basis on which to come to a conclusion on the matter—was the larger question of whether the tramway systems were still required to minister to the traffic needs of the metropolis. If he might say so, the author of the paper had only partially studied the problem of London traffic. Mr. Worby Beaumont seemed to imagine that London traffic flowed in an even flow. That was a fatal fallacy. London traffic had immense tides. Those tides of traffic were vital if the trade and industry of London were to be carried on. Mr. Worby Beaumont had called attention to the fact that an omnibus carried more passengers per seat provided than did a tramcar. That was admittedly the case, but why was that so? The tramcar was the only vehicle in London, on the surface of the streets, which dealt with rush hour traffic. No one was going to suggest that in the morning when a tramcar was carrying 120 passengers that it was not doing the utmost service to the metropolis. An enormous tramcar service was run purely on peak load periods. When there was little traffic the number of cars was reduced. The omnibus only took an even load, and did not attempt to deal with the glut of London

traffic. When the demand was at its highest the omnibus companies did not attempt to put an extra omnibus on the service. He had shown recently at another place that the load-curve of the motor omnibus was a dead straight line, but that the load-curve of the tramcar was an enormous peak going up in the morning, coming down low in the middle of the day, and going up again to an enormous peak in the evening rush hour period. In those circumstances the tramcar provided a much larger number of seats per passenger than did the omnibus, and naturally, therefore, the feature to which the author had referred, namely, that the omnibus, which only did an even load, had a larger number of passengers per seat than the tramcar, was true. But he asked the audience to suppose for one moment that the tramcar system of London was abolished and omnibuses substituted in its place. He was rather amazed to hear the author state that only a few more omnibuses would be required to carry the tramcar traffic. It was really amazing to think that the problem of providing accommodation for one thousand million passengers — 50 per cent. more passengers than were being carried by the omnibuses to-day—was a task which could be so lightly undertaken as the author had suggested. What did it mean? As he had said, at rush hour periods there were frequently not 78 passengers on a tramcar but 120. But even taking the lower number of 78, and comparing it with motor omnibuses, 2½ motor omnibuses would have to be provided to carry one tramcar load. That meant that whereas there were already more than sufficient omnibuses to carry the normal traffic in the middle of the day, there would be 2½ times as many omnibuses added for which there would be no work to do in that period. Under the labour conditions at present prevailing, it was impossible to run a transit organisation successfully unless a working day was provided for the staff. He would like the author to work out how many omnibuses would be required to carry the peak load of the County Council tramways; what was going to be done with the omnibuses in the slack hours of the day; how much the fares would be; and how the system was going to be operated? Mr. Worby Beaumont had alluded to the fact that at the present time the County Council tramways were working at a deficit, but he ought to have carried his observations further. He had stated that the County Council tramways would, in the ensuing year, make a loss of three-quarters of a million, but did Mr. Worby Beaumont know that, at a recent meeting, Lord Ashfield, the Chairman of the Omnibus Company, had mentioned that the loss which was going to accrue to the omnibuses during the coming year was £1,600,000? It was clear that the problem of London traffic must not be treated in a light-hearted way. It was a serious and difficult problem, in the solution of which had to be employed not one means of transit but every means of transit. He said emphatically that there was room in London for the tube railways, for tramways, and for motor omnibuses. Instead of a policy of competition, there should be a policy of co-operation. There should be introduced what at present was non-existent, namely, a more efficient road transit system in London. If there was co-operation instead of competition, he ventured to say that there would be no talk of transit agencies being bankrupt, but of those agencies ministering to what was the paramount need of London at the present time, namely, an efficient transport service for the metropolis.

Colonel R. E. B. Crompton, C.B., said he begged to call attention to the fact that Mr. Gordon had entirely missed the point. The question was the occupation of the surface of the London streets by traffic, how to minimise congestion, and how to move passengers over the streets with the least congestion, with the greatest rapidity, and with the greatest convenience. Therefore it resolved itself into the simple question—which vehicle could transport the greatest number of passengers in a given time over a given surface of roadway. He had supplied on a previous occasion the figures of what omnibuses could do at the present time, and what they would do when the new 46-passenger omnibuses were on the streets, as they would be very shortly; and Mr. Gordon had not answered those figures. He considered that Mr. Gordon had yet to prove that those figures were wrong. Those figures showed that the carrying capacity per yard, or per area of roadway, of motor omnibuses as they were now was nearly 50 per cent. in excess of the carrying capacity of the tramways occupying the same road surface; and with a 46-passenger omnibus it would be doubled. But that was only one aspect of the question. He thought the majority of engineers were with him when he said that the advent of the motor omnibus, and the amount of thought and design brought into the motor omnibus, had rendered the tramcar completely obsolete. The tramcar was an obsolete piece of engineering. Again, it was the most obstructive thing possible in the streets, particularly in South London. Tramcars had been laid through streets through which they never should have been laid. The space on the near side between them and the kerb was so small that no other vehicle could pass, so that a slow vehicle running alongside the tramway held the road and prevented any faster vehicle from passing. The tramcar with its excessive weight and size was an obsolete vehicle occupying twice the space of a motor omnibus, and was so obstructive that it ought to be done away with as early as possible.

Mr. Henry Ward, L.C.C., said he was surprised to find two engineers of such eminence as Mr. Beaumont and Colonel Crompton stating that rail-borne traffic, such as trams, was likely to give way to road-borne traffic. If that were the argument, it might almost be said that road

transport would do away with the railways, and that all passengers and luggage would be carried along the road. The power required by rail-borne was so much less than that required to carry weight on roads that the former would always beat road-borne traffic. Mr. Worby Beaumont had started by begging the question. He had asked why the public preferred the omnibuses. He (the speaker) had thought the audience were going to be given proof of that statement. As a matter of fact he, the speaker, wanted to know why the London public preferred the tramcars, and he could give the reasons why they did so. The cubic space which a passenger had on a tramcar was nearly double that which he had on the omnibus. The vibration on a tramcar travelling on the road was far less than that on an omnibus. Nobody would contend that the ventilation in a tramcar was not superior to that in an omnibus, and again what discomfort did a poor passenger undergo on the top of an uncovered omnibus in wet and stormy weather? It was true that in order to provide that superior comfort on the part of a covered-in tramcar its weight had largely to be increased, and that unfortunately increased the strain on a tramcar very much more than the extra weight would involve, because the weight was put up at a great height, and therefore acted with a big leverage when it had to be transferred to the rails. Another point in the tramcar's favour was that it alone dealt with the rush load. Further, it dealt with the great problem which was vital to all municipal transport, namely that our centres of population were now becoming so congested that the people must, by hook or by crook, be carried to the outskirts. The working population could not afford to pay omnibus fares night and morning, and the result was that the carrying of workpeople backwards and forwards to the outskirts was not undertaken at all by the omnibus but by the tramcar. That was one piece of work which the tramcar would always have to handle to the exclusion of the omnibus. With regard to the loss on the London tramways, that was reckoned not as it was reckoned on the omnibus line. The London County Council first had to pay all their dividends in the form of interest to those people who had lent the money. It was only after that that they began to mention loss, whereas the omnibus company simply paid no dividend at all, and so long as its income and expenses met it might be said that they ran without loss. Another point was that every year the County Council had to pay off nearly half a million of its capital. They had paid six millions from their income out of fourteen millions of capital, and that was charged as costs of working the cars, not merely interest to those who had lent the money. That very heavy sinking fund would enable the tramways to be handed over free of cost to the ratepayers as a going concern at the end of something like twenty-five years—a very different state of affairs from that of the omnibus company. The author had not written a paper on the Transport of London, but had given a contribution which praised omnibuses and did not mention a single one of their defects, and which from end to end damned the tramways.

Mr. H. Percy Boulnois said that, having had control of tramways and also having had a large control of roads during his lifetime, he ventured to state that he could not help thinking that the London County Council had now found they were backing the wrong horse and were trying, in common phraseology, to camouflage the position. They were losing money on the tramways and they would continue to lose it. To his mind the tramcar was not either a mechanically designed vehicle nor was it a convenient vehicle. With regard to the peak loads and the rush hours, they could equally well be dealt with by omnibuses if there were a sufficient number of them, and to prove that statement he had merely to point to the instance of Victoria Station where people coming from the trains were distributed in every direction by the omnibuses there waiting for them. The speaker then proceeded to give a list of defects connected with the tramway, mentioning the lack of mobility of tramcars—tramcars having to follow each other in a rigid line and not being able to move to right or left; the fact of passengers having to get off in the middle of the street with the consequent danger attached thereto; the fact that the cars were the greatest obstructors of traffic ever introduced; their excessive grinding noise; and the great annoyance caused to the sleeping population by the fact of repairs having to be done during the night.

Mr. G. H. Hume (L.C.C. and Member of the Advisory Committee on London Traffic) said if he had shut his eyes during the delivery of the paper he should have imagined that he was listening to an expert witness in the Law Courts called to defend one particular side of the question. Everything had been said that could have been said in favour of the omnibus, and nothing at all had been said in favour of the trams. He personally did not desire to go into the question of the omnibus versus the tram. The traffic authorities in London had a far greater problem than that to consider. The traffic problem in London was not merely one of congestion but how to get the population backwards and forwards. The present was no time to shut down any means of conveyance. The number of journeys per head of the population was increasing rapidly, and it was absolutely essential that an endeavour should be made to mobilise all means of transport in order to meet the situation. Whether trams were obsolete or not, they were very badly needed in many parts of London in order to meet the present need, which need could not be met otherwise. Omnibuses had not attempted to meet the demand of the peak load period. The London County Council were not against motor omnibuses; in fact they were seeking powers to run them. The question of tramways versus omnibuses seemed to

those who were in the thick of the problem almost like a childish exercise. The deadly part of the matter was that if statistics from a controversy of such a kind came to the ears of the legislators at the present moment it might well induce them on partial consideration of the question to refuse the offer of the London County Council. The London County Council was offering to solve the problem in a practical way, and was saying that in spite of the cost they were going to try to meet the public need by laying down forty more miles of tramways. There was nothing else in the field to deal with the situation, and the danger of a paper of the kind which had been given that afternoon was, as he had said, that it might induce the House to refuse the London County Council's offer, which, if refused, might not be made again.

MR. W. M. ACWORTH said it was rather a pity that the discussion, which he thought was to have been a discussion on the best means of solving the problem of London traffic, had come to be a discussion on the question of whether the London County Council was or was not a virtuous public servant. He could not help feeling that that was a mistake. He could agree with Mr. Hume that at the present moment, at any rate, to talk of getting rid of the tramways was not practical politics in the interests of London. He did not think it was desirable to discuss the abolition of tramways at the present time, but when it came to a matter of extensions that, he thought, was a point on which people were entitled to hold a different opinion. The County Council were proposing to bring tramways past Westminster Abbey, past Marble Arch, and across the foot of Ludgate Hill. That was an entirely new departure. It meant the trams were coming into some of the most important and congested traffic centres in London. He did not think that was a step which should be taken without more general approval. That the approval was not general was proved by the fact that there were some eighty odd petitions against the London County Council Bill in Parliament, which petitions included practically every local authority in the middle of London. Dealing with the present situation, there were two points which had to be considered. One was the peak load. Nobody was going to argue that under present conditions the omnibuses could deal with the peak load. That was perfectly clear. The tramways were there, and for that purpose were at present essential. The future was another matter. But, meanwhile, the fact of the peak load had to be faced, and it did seem to him that it ought not to be past the wit of man to make some arrangement by which omnibuses and the tramcars could be worked in harmony to do the best they could for dealing with what were two perfectly different things, namely, the traffic as it existed along Oxford Street where it was much of a muchness all the day long, and the traffic which came from the outskirts to the centre of London. The other point was that the tramways had got to accept the fact that London being what it was they could not do what the omnibuses could do. They could not, for instance, go up Bond Street. He really could not imagine that tramways could be worked up Bond Street to the greatest happiness of the greatest number. If that were so, there was a separate field left for the omnibuses. As to how big it was, Mr. Gordon and himself would probably disagree on the details, but he could not help thinking that they would agree that there were points which the omnibus could reach, and districts which the omnibus could serve, which the tramcar could not equally well serve. It did seem to him a pity that the different people interested were not getting together on points of that kind, and seeing whether something could not be done which would save London from the grossest inconvenience for at least the year to come. He thought it very desirable that those interested should get together and try to find whether they could not, by a co-ordination of the machinery available, make a better result for London as a whole than it was possible to do under present conditions.

MR. WILLIAM WORBY BEAUMONT, in reply, said the remarks of Mr. Gordon during the discussion and also his remarks which he had made on a previous occasion, showed that he was almost incapable of seeing anything on the subject unless he saw it through a tramcar window. He need hardly say that he agreed with Colonel Crompton's remarks. With regard to Mr. Ward's remarks, he would simply say, in order to cut the matter as short as possible, that he too saw things only through a tramcar window. With regard to Mr. Boulnois' remarks he had nothing to say in reply, because no one could object to them. With regard to Mr. Hume's remarks, Mr. Hume, like other speakers, spoke of the matter as purely a tramcar question, and practically expressed the view that everything else must be subordinated to tramway matters. With regard to Mr. Acworth's remarks, he (the author) had not been discussing so much the abolition of any system; the argument was that the proposed new extension should not be carried out. Not one of the speakers who had adversely criticised his remarks concerning tramways and tramcars in London had controverted a single one of the salient facts or reasons given in the paper.

THE CHAIRMAN, in moving a vote of thanks to the author for his paper, said the paper had rather tended to increase the mental indigestion from which he had been suffering for some months. During the last hour and three-quarters he had felt very much in the position of the small boy who, having surfeited himself with mince pies on Christmas Day, was asked at the end of the day if he would not try just one more, and his digestion did not rise to the occasion. He (the Chairman) had suffered, and was suffering, from mental indigestion concerning traffic statistics and figures, and the question of the values of the

different vehicles and different methods of transport, because they had been produced in excessive quantities. It had been his fortune in the last nine months to preside over two committees dealing with the question of London traffic, and incidentally inquiring into the transit values of tramcars, tubes, buses, and various other forms of vehicles. His second committee had still to report, and therefore personally he must for the time being remain silent as to any phase of the very interesting paper which had been presented that evening. He was very glad to see so many people present prepared to study the question of London traffic, because until the public themselves had a very shrewd appreciation of all the difficulties, it would not be possible to do very much in the matter; but he would warn them from his experience that if they entered into the study of traffic, thinking that the acquisition of knowledge on the matter was an easy task and that they could discover remedies after a few hours' consideration, they would soon find that that was not the case. He would further warn them that they would venture on to a battlefield where tables of figures would be thrown at them, and where the arguments of the parties on both sides would be bewildering and confusing. On the previous day he had had no knowledge of the character of the paper; if he had, he did not think he should have been present, because painful experience had taught him to approach the controversial aspects of the traffic problem with the utmost caution, and he hoped always with due modesty. Anyhow, there was the fact that if people were going to approach the question they should consider it in its wide and broad aspects rather than from the point of view of whether the tram was better than the bus or the bus better than the tram.

The vote of thanks was then put and carried, and the meeting terminated.

Mr. A. A. Parsons, of the Palmer Tyre, Ltd., writes:—Metropolitan motorists generally appear to appreciate the dangers their tyres are exposed to from defective tram-rails and points. Speaking as tyre makers we find fewer cases of tyres damaged in this way coming under our notice for repair than was the case eight or ten years ago, and as the condition of the tramway tracks in London has very much deteriorated in the meantime, and particularly during the last four or five years, we can only attribute this falling off to greater care on the part of motor-car drivers. It is noticeable to anyone who does much driving in London, that drivers avoid as far as possible running with either near or off-side tyre directly on the rail, and are particularly careful at junctions and cross-overs. In the case of experienced drivers, it is only when they are forced directly on to the rails that they run any serious risk. Vulcanised rubber of good quality is not easily cut, and it is generally known that if rubber has to be cut with a knife water is the best lubricant. In the course of conversation with car owners we have found that in the majority of cases injury to the treads of tyres from knife-edge tramway points has usually been caused when the track and tyres are wet. The injury, as a rule, consists in the slicing off of a piece of tread of an irregular shape with an area of from six to ten square inches. Very frequently the piece of tread is not entirely detached. Our theory is that most of these mishaps are due to the tyre slipping on the smooth and sometimes greasy surface of the rail while a portion of the tyre tread is in contact with the knife-edge of a badly worn point. It is usually at junctions that motorists have to slow down, and it is quite conceivable that what we have described may easily happen while the speed of the car is being retarded or in accelerating after having been brought to rest or nearly so. Our theory seems to be confirmed by the fact that it is almost invariably the driving-wheel tyres which sustain injury. It has been quite a common thing within the last few years to see lengths of the running surface of the tramway rail broken away for a space of from 18 inches to 3 or 4 feet. This, as far as our observation goes, generally occurs where the granite sets are some inches below the rail head. In such cases the jagged edge of the rail thus exposed is likely to cause injury to pneumatic tyres, but we have not been able to trace any serious percentage of tyre damage to this cause. Mishaps such as we have described undoubtedly prove a form of indirect tax on the motorist. Satisfactorily to repair the sliced tread would cost from £2 to £3, according to the size of the tyre. If the car owner neglects to have the tyre repaired and continues to use it in its damaged condition the total mileage, in the case of a comparatively new tyre, is usually reduced by something like 40 per cent., because the foundation is naturally first exposed at the point where the rubber has been cut away from the tread. If the average price of a tyre at the present time is taken at £8, it means that mileage to the value of something like £3 4*s*. has been lost to the motorist. On looking through our records it would appear that the tyres received from London users classified as being, in our opinion, injured by tramrails only represent ·5 per cent. of the total number of our tyres estimated to be in use in greater London, so that it cannot be said that the conditions of the tramway tracks—bad as they are—are responsible for any great mortality of tyres, and it should be remarked that the cases in which the foundation of the tyre is damaged at the same time as the tread are extremely rare.

Mr. E. H. Beckwick, of Chas. Macintosh & Co., Ltd., writes:—Tramlines always have been looked upon as being very detrimental to any rubber tyre, and more especially where, through road repair neglect, they are allowed to project above the level of the adjacent paving. This is more particularly the case at junctions, which are usually so crowded with traffic that it is impossible for the most careful driver to avoid them, and this, of course, is highly prejudicial to us as tyre manufacturers. Apart from tyres, the damage caused

to the axle and wheels of vehicles by tramway metals is enormous, and their abolition in favour of some more modern means of transit would, I have no doubt, receive the grateful thanks of every vehicle owner using the streets of London.

MR. GUY BEAUMONT, A.M.Inst.C.E., writes:—The subject dealt with by the author renders comparison of available passenger transport methods both desirable and unavoidable. I should like to be permitted, as one of those present, to express disagreement with some of the stated opinions of those contributing to the discussion. I do not find in the paper any proposal that the passenger transport facilities should be curtailed by reduction of any of the several systems now working, but there is, on the contrary, an undoubted appeal to logical consideration and impartial investigation of relative merits in order to secure future improvement. This is indicated by the early occurrence in the paper of the following sentence: "For the future then the question arises: What shall be the means of transport—the tramway and tramcar, tramcar and trailer, or the motor omnibus?" Mr. H. H. Gordon stated that the omnibus could not deal with the peculiar difficulty of rush-hour traffic, and referred the meeting to the lecture recently delivered by him before the Institution of Civil Engineers upon "Some Aspects of Metropolitan Road and Rail Transit." In this lecture the following information is given or definitely indicated by included diagrams (see p. 36, Fig. 10). On a typical popular route over an eighteen-hour period, motor omnibuses carried 67 per cent. and tramcars 33 per cent. of the the total passenger traffic of the two systems. During the rush-hour period—8 to 9 a.m.—the omnibuses carried the same number of passengers as the tramcars within 3 per cent., and if the period 8 to 10 a.m. be taken the omnibus totals much exceed those of the tramcar. The same or nearly the same proportions obtain for the evening rush-hours. These figures, derived from Mr. Gordon's paper, conflict with his statement in the discussion, but they do support my experience in observation of the working of both tramcars and omnibuses at rush-hour periods. The figures quoted in the same lecture (see p. 23) also indicate that the omnibus is a very large and much-appreciated contribution to the London passenger transport facilities. I desire to take the opportunity afforded by the reading of this paper to concur in the statements of those who, in the discussion, claimed that the motor omnibus method is already demonstrated to be superior to the tramway method of dealing with metropolitan passenger traffic, and that the time has come for courageous and unequivocal decision in favour of the better system, and for effecting the change as rapidly as public convenience and financial consideration permit. In conclusion, it is interesting to note that the author pays a well-deserved tribute to the tramway engineers and managers, and records the disadvantages they have had to labour against.

OBITUARY.

THEODORE N. VAIL, LL.D., D.Sc.—The death is reported from New York of Dr. Theodore Newton Vail, who was elected a Fellow of the Royal Society of Arts in 1916. He was born in Carroll Co., Ohio, in 1845. After studying medicine for two years he entered the engineering profession. In 1873 he was appointed assistant superintendent of the railway mail service, Washington, and rapidly rose to the position of general superintendent. But his principal work was done in connection with the telephone service. For ten years he was president of the American Telephone and Telegraph Company, in which period the "Bell" telephone system in the United States increased from 6,000,000 stations to nearly 12,000,000, and the range of the telephone was extended until it covered the whole continent, and New York was able to speak with San Francisco. Dr. Vail fully recognised the importance of scientific research, and during his presidency of the company he organised a research department, which is probably unsurpassed in the world to-day among technical laboratories. The enormous development of the telephone service in America is very largely due to his efforts.

Dr. Vail was well known in London, where he lived for several years at a time when he was busy developing electrical enterprises in South America.

GENERAL NOTE.

FRENCH RAILWAYS AND THE WAR.—During the four and a half years of war the French railways have rendered great service to the national defence in the transportation of vast quantities of war material, food supplies, troops, etc., notwithstanding almost insurmountable difficulties. The Paris-Lyon-Méditerranée system in five weeks ran 1,600 extra trains, making an average total of 45 trains per day. In 1915 the same system transported 70,000 Sikhs and Gourkas, who had been landed at Marseilles. In the same year the Orleans system ran 400 trains, at times at six-minute intervals, to carry Hindoo troops from Toulouse to Orleans. The Southern Railway transported 600,000 men and 96,000 horses and mules. During 1915 also the Northern system operated more than 114,000 trains, or an average of 320 trains a day, not including hospital trains and those carrying soldiers or munitions of war. In 1915, for revictualling the army in food products and munitions of war, 60,000 complete trains, or an average of over 160 per day, were operated by the Northern Railway; the Southern Railway carried 617,000 tons of food products and munitions and 584,000 tons of various kinds of merchandise; the Orleans system carried 11,000 guns and cartridges, and in addition ran about 85,000 loaded cars. And from August 20th to September 30th, 1914, the latter railway carried 117,000 tons of food products, 65,000 tons of forage, 107,000 cattle, and 215,000 head of sheep and hogs to feed Paris.

Journal of the Royal Society of Arts.

FRIDAY, APRIL 30, 1920.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

MONDAY, MAY 3rd, at 8 p.m. (Cantor Lecture.) ARTHUR THOMAS BOLTON, F.R.I.B.A., F.S.A., Curator, Soane Museum, "The Decoration and Architecture of Robert Adam and Sir John Soane, 1758-1837." (Lecture I.)

WEDNESDAY, MAY 5th, at 4.30 p.m. (Ordinary Meeting.) DR. C. E. KENNETH MEES, "A Photographic Research Laboratory." SIR HENRY TRUEMAN WOOD, Chairman of the Council, will preside.

Further particulars of the Society's meetings will be found at the end of this number.

CANTOR LECTURE.

Owing to a sudden attack of influenza, DR. WALTER ROSENHAIN, F.R.S., Superintendent of the Department of Metallurgy and Metallurgical Chemistry, National Physical Laboratory, was unable to deliver the third lecture of his course on "Aluminium and its Alloys" on Monday, April 26th. It is hoped to arrange another date for the lecture, and notice will be given in the *Journal* as soon as this is fixed.

EIGHTEENTH ORDINARY MEETING.

WEDNESDAY, APRIL 28th; THE RIGHT HON. LORD DESBOROUGH, K.C.V.O., in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Anderson, Sir Alan Garrett, K.B.E., London.
Dunning, Major James, D.S.O., London.
Hart, Charles, F.S.S., Moseley, Birmingham.
Howard-Flanders, Richard Leonard, M.I.Ae.E., Latchingdon, Essex.
Kneass, Strickland L., Philadelphia, U.S.A.
Mayrow, J. J., London.
Sherrill, Brigadier-General Charles H., LL.D., New York, U.S.A.
Visvesvaraya, Sir M., K.C.I.E., M.Inst.C.E., London.

The following candidates were balloted for and duly elected Fellows of the Society:—

Abbott, Hon. R. H. S., Bendigo, Victoria, Australia.
Allen, William Thruston, Waipiro Bay, New Zealand.
Buchanan, John, Port Sunlight, Cheshire.
Cross, L. W., London.
Hitchcock, Eldred Frederick, C.B.E., London.
Mansukani, Gulab, M.B., B.S., London.
Marshall, Mrs. M. Katherine, Totley, nr. Sheffield.
Mather, Frederick, B.Sc., Barcelona, Spain.
Matsukata, Goro, Tokyo, Japan.
Savi, Ernest E., London.
Taylor, Captain T. Smithies, Steep Petersfield, Hants.
Wheeler, Major Charles, R.A.S.C., O.B.E., M.I.A.E., Bushey, Herts.
Yorke, Mrs. Constance E., F.R.G.S., Southsea, Hants.

A paper on "Ancient Stained Glass" was read by BRIGADIER-GENERAL CHARLES H. SHERRILL, LL.D., of New York, U.S.A.

The paper and discussion will be published in a subsequent number of the *Journal*.

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

A meeting of the Indian Section was held on Friday, March 19th, 1920; THE RIGHT HON. LORD CHALMERS, G.C.B., LL.D., in the chair.

The paper read was—

THE INDIAN CURRENCY SYSTEM AND ITS DEVELOPMENTS.

By SIR WILLIAM MEYER, G.C.I.E., K.C.S.I.

Controversies on currency matters are sometimes waged with an almost religious fervour, but I do not propose to devote the paper I am about to read you to polemical preachings. My object is less exciting, but perhaps more useful—to give you a short historical account

of the origin of the Indian currency system and the ways in which it has been developed to meet the stress of very varying circumstances. And these circumstances have been so specially novel and difficult during the last few years that I think it may be of value to show how what has been done to meet them links on with the past, and what the evolution and recent trend of currency policy in India have been. In doing this I must necessarily survey ground which is familiar to many of you, but a bird's-eye-view is often useful even to those who are thoroughly acquainted with the details of the landscape.

Our currency system in India was founded on that of the Mughal Emperors, whose heritage we gradually took over. Akbar took as a basis of his currency the *rupee* (or silver piece), and this superseded a coin called a *tanka*, which was in its turn linked on to the old Hindu monetary system. Akbar's rupee had a weight of about 180 grains gross and 176 pure silver, and he also issued a variety of gold coins, the commonest of which was worth 10 rupees. The Mughals had many mints, and as their empire foundered, these were increased by the coinages of the now practically independent viceroys of the Hindu States which were emerging from the ruins. In these troublous times the coinage was gradually debased in many local mints until the country was filled with rupees of various different values. The best issues were those of the Murshidabad mint in Bengal, of Lucknow (or Farrukhabad) in Oudh, of Arcot in Southern India, and of Surat on the Bombay side.

The first British mint in India was established in 1671 in Bombay, to provide a local coinage for the island and its neighbourhood, and it is on record that the Emperor Aurangzeb was greatly displeased with the issue by the English of rupees "bearing the name of their impure king."

As the Company established itself as paramount power in India, the four denominations of rupees above referred to gradually replaced the old miscellaneous coinages. The Murshidabad issue, which was the only one that had maintained Akbar's original standard, became the current coin of Bengal and was known as the *sikka* rupee. The Lucknow (Farrukhabad) rupee became the standard for what is now the United Provinces, the Arcot rupee for Madras, and the Surat rupee for Bombay. There were a variety of gold coins current during this time, the most important being the gold mohur (Rs. 15), and the pagoda (Rs. 3½), which up to 1818 was the currency basis in Southern India.

In 1835 a uniform coinage for India was for the first time introduced, and the rupee standard adopted was that of Madras (Arcot), with a weight of 180 grains and containing 165 grains pure silver, a standard which has ever since been adhered to. This rupee was, and is, legal tender without limit, and its weight, one *tola* (a little less than half an ounce), is also the unit on which the Indian standard weights are based. Each rupee is worth 16 annas, and other silver coins were until recently the 8 as. piece which, like the rupee, was legal tender without limit, and the 4 as. and 2 as. pieces which, like the copper coins, were legal tender only up to one rupee. The copper coins were the ½ anna and ¼ anna (there has never been a copper anna piece) and a pie, equal to one-twelfth of an anna.

In 1906, bronze coins were substituted for copper, and a one anna nickel piece was introduced, while quite recently nickel pieces of 2 as., 4 as. and 8 as. have been issued to replace the corresponding silver coins, all these being legal tender up to one rupee only. The recent Exchange and Currency Committee have, however, recommended that if this limit should prove inconveniently low in the case of the 8 as. nickel, it should be raised to Rs. 5 or 10.

The 1835 Act authorised the coinage of various gold pieces. These coins, however, had no independent legal tender value, but were appraised at their market value as compared with the rupee, and presently gold coinage in India fell into complete abeyance.

The normal sterling value of the rupee was taken at 2*s*., *i.e.* it was treated as the equivalent of the British florin.

The mints, which were gradually reduced to two, those now existing at Calcutta and Bombay, were open to the free coinage of silver. Anyone could present silver bullion there and get it coined at a small seigniorage into an equivalent number of rupees. I may mention here that the principal Native States retained their rights of coinage, but these have been gradually surrendered in most cases, a policy which was materially developed by the closure of the Indian Government Mints to the free coinage of silver in 1893, which led, as will be explained presently, to the British rupee rising to a high premium as compared with its bullion value, while the Native States rupees remained on the old bullion footing. At present the most important State which maintains a coinage of its own is Hyderabad, and it had to take measures somewhat analogous to those adopted in British India to keep its rupee above the bullion level.

The supplementing of specie coins by a paper currency was of slow and gradual growth in India. There were always bills of exchange (*hundis*) issued by Indian bankers and *shroffs*, which, if the issuer was a person of accepted reputation, were readily negotiable; but the issue of notes by or on the authority of the State was unknown prior to British rule or in its early stages. By Acts passed between 1837 and 1843 the Presidency Banks of Calcutta, Bombay and Madras were permitted to issue notes payable on demand, but the circulation of these was practically confined to the cities in which they were issued. In 1861 the present note system was initiated; the privilege of note issue was withdrawn from the Presidency Banks and made a State function; and the denominations of the notes to be issued were fixed at Rs. 5, 10, 20, 50, 100, 1,000 and 10,000 (the Rs. 20 note was, however, withdrawn some years ago). For the purpose of this system India was divided into various currency circles, which now have their headquarters at Calcutta, Bombay, Karachi, Madras, Cawnpore, Lahore, and Rangoon, and the notes issued in each circle were legal tender within it and payable on demand at the circle headquarters. In circles other than their own the notes were subject to a slight discount representing the cost of sending them "home" for payment. The object was to obviate the strain which would have been caused at particular centres by free transmission and encashment of notes from other parts of the country; but in course of time it was recognised that to make the smaller notes really popular it was necessary they should be universalised, *i.e.* made payable at any currency centre. This step was taken in connection with the Rs. 5 note in 1903, and a few years later the Rs. 10, 50, and 100 notes were similarly treated. There was, and there is still, no obligation on the part of the Government to encash their notes outside the currency centres, but as a matter of convenience they were to some extent cashed also at local treasuries. I will return to this point later on.

The note circulation began, and at first progressed, in a small way, as was natural in a country which had had grievous experience of political cataclysms and of the debasement of coinage by a succession of Governments, and where the hoarding instinct was, in consequence, strongly developed. In 1870 the total value of the notes in circulation was about $10\frac{1}{2}$ crores of rupees; in 1880 about $12\frac{1}{3}$; in 1890, $15\frac{3}{4}$; and in 1900, $28\frac{3}{4}$.

The encashment of notes was provided for by the establishment of a paper currency reserve, which has played a great part in the problems of recent years, and which was constituted on the English system, *i.e.* a certain amount of the reserve, fixed by legislation from time to time, and representing a portion of the notes outstanding not in the least likely to come in for encashment, was permitted to be held in Government paper; the remainder had to be the exact equivalent in rupees or silver bullion of the balance of the note issue. The invested portion, which was originally fixed at a maximum of 4 crores, had by 1896 been increased to 10, all of which was required to be held in Government of India securities. In 1905 and 1911 a further expansion of 4 crores was permitted, and this was allowed to be held in securities of the United Kingdom.

As regards international exchange, the position was, and still is, that in normal times India exports considerably more than she imports, and there is consequently a large debt owing to her year by year in London, the world's clearing-house for Indian transactions. *Primâ facie* this would have to be defrayed by the export of specie to India, which has, from the time of Pliny on, shown an avid demand for the precious metals; but, on the other hand, India, as represented by her Government, has to make large remittances to London to meet what are called the "home charges"—expenditure in connection with the purchase of stores, material, pension and leave allowances, certain military charges, interest on her sterling debt, and so forth. These were defrayed, to the advantage alike of the Government and trade, by the Secretary of State selling for sterling rupee drafts on the Indian treasuries, a practice which was regularly introduced in 1862, though it had been carried out intermittently for some thirty years previously. These sales ere long became of weekly occurrence, and were to the highest bidders; but the sterling amounts obtained could not normally exceed the cost of procuring silver and remitting it to India for coinage, since that was an ever open alternative. Consequently, allowing for such minor variations as temporary trade conditions may set up between any two countries, the value of the rupee in sterling was conditioned by the world-ratio of silver and gold, which up to 1873 was fairly constant, and resulted in the Secretary of State's council drafts being sold at rates ranging from nearly 2*s*. per rupee in 1861–2, to nearly 1*s*. 11*d*.

in 1872–3 (I am quoting the average figures for each year).

Up to this latter date the system I have described had worked smoothly and easily; additions to the coinage and note issues took place automatically on presentation of bullion at the mints to be exchanged for rupees or note; and the imports of silver and gold (the latter being in demand for use in arts, ornament and hoarding) was left to private enterprise. In the decade 1865–74 the average annual import of silver was about 6¼ crores of rupees, the bulk of which was passed into the mints, and of gold about 3⅔ crores. The Secretary of State's council drafts were merely for the purpose of meeting his home charges, and trade was left to make its own arrangements for the provision of currency in India in excess of the sums they represented, while the paper currency reserve was confined to its original purpose of providing resources (in India) for the encashment of notes. But in 1873 the commencement of trouble began as the result of the fall in the value of silver as compared with gold, initiated by Germany's silver demonetization, and in consequence the rupee exchange kept dropping till the average rate for 1892–93 was only about 15*d*. This depreciation cannot be said to have materially affected India's foreign trade; indeed, in some cases the low rate stimulated exports; but to the Indian community as represented by the State the results were disastrous. The burden of liquidating the home charges was greatly increased, the Indian budgets were constantly dislocated by fresh falls in exchange, and the much-needed investment of British capital in Indian enterprises was checked by the well-founded fear that investors, when they wanted to realise their money in sterling, would have to do so at a material loss. Efforts were made by the Government of India to remedy a position which for them was becoming desperate by an international agreement for bimetallism, but these proved unsuccessful, and it became evident that India must act on her own account in the direction of putting the rupee on a basis independent of its bullion value. It was consequently decided, on the recommendation of a committee presided over by the late Lord Herschell, that the Indian mints should be closed to the free coinage of silver, and that this should only be undertaken on behalf of the Government. The object was, of course, to enhance the exchange value of the rupee by giving it a scarcity premium, for the settlement of India's net trade balances would now have to take place mainly through the Secretary of State's council drawings, the old alternative method of sending silver bullion to India for coinage being no longer available. It was hoped that in this way, and by refraining from fresh coinage, the exchange value of the rupee would soon be forced up to 1*s*. 4*d*., the permanent standard which the Herschell Committee had set before them. This method proved, however, to operate but slowly, as the closure of the mints brought large amounts of previously coined rupees out of hoards, and meanwhile the rate of exchange went on falling with the diminishing bullion value of silver, the average figure for the year 1894–5 being only 1*s*. 1*d*., while for 1896–7 it was still somewhat less than 1*s*. 2½*d*. This position daunted even the stout heart of Sir James Westland, the then Finance Member of the Viceroy's Council, and he suggested that it might become necessary to reduce the standard to be aimed at to 1*s*. 3*d*., and to expedite its attainment by melting down large quantities of rupees. Fortunately, events made it unnecessary to consider such a course, for from 1897–98 the effects of the closure of the mints came into full operation, and by 1898–99 the goal had been reached and the rupee, though its bullion value was then only about 10*d*., had been screwed up to an exchange value of 1*s*. 4*d*., which it was to retain, subject to such minor oscillations as are inevitable in any foreign exchange system, for nearly twenty years. Facts thus emphatically disproved the contention of many economists at the time the mints were closed that it would be impossible to maintain such an artificial system, and that the large gap between the bullion and exchange values of the rupee would flood India with counterfeit coin. There was always, of course, the risk of counterfeiting, which had to be carefully looked to; but, as a matter of fact, the counterfeit issues were small and largely of such a crude nature that they were easily detected.

Meanwhile the whole position had been carefully considered by a strong Committee in London under the chairmanship of the late Sir Henry Fowler (afterwards Lord Wolverhampton), himself a former Secretary of State, whose report, presented in 1899, formed the basis of Indian currency policy until the cataclysms produced by the late war made further changes inevitable. One of the Assistant Secretaries on that Committee was my great friend, and the close friend of many of you present to-day, the late Sir Lionel Abrahams.

who thus initiated a close connection with Indian currency and finance which he was to develop subsequently, first as Financial Secretary and then as Assistant Under-Secretary of State at the India Office. For some twenty years our late friend was continuously connected as no one else was with India's financial problems, and she owes an immeasurable debt to the profound knowledge, intuition amounting to genius, industry, and selfless devotion which he gave to her interests. He literally wore himself out in India's service, and his untimely death a few months ago inflicted a loss on the India Office, and through it on India, which may be described in the most literal sense of the term as irreparable.

The Fowler Committee fully endorsed the policy of closing the mints and of maintaining the exchange value of the rupee at 1*s.* 4*d.*, and then proceeded to consider what steps should be taken to make this policy effective. As was inevitable in the circumstances in which they were appointed, the Committee were keenly impressed by the necessity of protecting the artificial value of the rupee from any breakdown which might accrue from over-coinage. Accordingly, while retaining the rupee (and half rupee) as full legal tender, they laid stress on the necessity of encouraging the use of gold in the currency. When the mints were closed it had been notified that sovereigns and half sovereigns would thereafter be received by Government as the equivalent of Rs. 15 and 7½ respectively, and that gold coin and bullion as well as silver would be held in the paper currency reserve as a backing against notes. The Committee now proposed that the sovereign and half sovereign should, *pari passu* with the rupee, be legal tender to an unlimited extent, and that the use of gold as currency should be encouraged by the coinage of sovereigns in India, while fresh rupee coinage, which had been in abeyance since 1893, was not to be resumed till the gold in the paper currency reserve had reached an inconvenient amount. The obligation to give rupees in exchange for sovereigns and half sovereigns was to be maintained, but the converse exchange of gold for rupees was not to be undertaken except as a matter of convenience, in respect of which no obligation would attach. When rupee coinage was resumed, it was recommended that, to guard against the risk of a turn of the tide making the rupee issues redundant and thus weighing down exchange, the profit on coinage, *i.e.* the difference between the actual cost of turning out rupees and their 1*s.* 4*d.* value, should be credited to a special fund, now styled the gold standard reserve, which should be used when necessary to maintain exchange by the issue of gold. The Committee's policy was fully accepted by the Secretary of State, but the scheme of coining sovereigns in India fell through owing, one must frankly say, to the obstructive attitude of the Royal Mint and the home treasury.

In 1899 an Act was passed making sovereigns and half sovereigns legal tender in India at Rs. 15 and Rs. 7½ respectively, and the internal ratio thus prescribed was the only statutory endorsement of the 1*s.* 4*d.* rupee. The gold standard reserve was constituted in 1901, but has never been on a statutory basis; while in 1898 an Act had been passed permitting the issue of notes against gold deposited in London (as well as in India) and held there as part of the paper currency reserve. The provisions of this Act, though at first temporary, were subsequently made permanent, and permitted the purchase of silver bullion for coinage in India out of the paper currency gold in London and the holding of such bullion, pending its coinage, as part of the reserve.

The system thus initiated was in effect a sort of local bimetallism. It is somewhat confusing, as is sometimes done, to speak of its having reduced the rupee to the position of a token coin, for the essence of an ordinary token coinage, such as our British silver pieces, is that it is only legal tender up to a very limited amount, whereas the rupee's legal tender functions are unlimited. The system provided adequately for the safeguarding of a situation in which the bullion value of the rupee was less than its exchange value. But if the bullion value of the rupee were to exceed 1*s.* 4*d.*, a position which may be taken as arising when the price of silver exceeds 43*d.* per ounce, the system, as events have proved, was bound to need reconsideration. At the time it was framed, however, this was not regarded as a practical possibility; indeed, when I assumed office as Finance Member in 1913, while I recognised that I might on occasion be caused anxiety over the maintenance of the rupee at 1*s.* 4*d.*, I never dreamed that a time was approaching in which one's preoccupation would be to keep it from soaring unduly above that level.

I remarked just now that the closure of the mints prevented the defrayal of a trade balance due to India, in so far as this could not be met through the Secretary of State's council draw-

ings, by the previous method of sending out silver to be coined into rupees. It was now possible to defray this balance by sending out gold, but to do this to a full extent would have caused embarrassment to the London money market, while it would have been inconvenient to India, which was not ripe for a gold currency of any large extent; and as most of the sovereigns and half sovereigns that came out were tendered to Government in exchange for rupees or notes, the paper currency reserve would have been unduly clogged with gold. A trial of paying Government obligations in gold was made in 1898, but had to be withdrawn by reason of its unpopularity. I remember asking one of my Indian clerks at the time how he liked the new system, and he replied: "Not at all, sir; formerly my wife used to let me keep some of the rupees I got, now she takes all the sovereigns for ornaments." The Government of India had originally estimated that a gold holding of more than £5,000,000 in the paper currency reserve would be inconvenient, and this sum was materially exceeded in 1900, necessitating the resumption of rupee coinage. Accordingly, it was decided that the Secretary of State should expand his council drawings, as far as possible, to meet the demands of trade, and in 1898 he notified that he would sell telegraphic transfers on India without limit at 1*s*. $4\frac{5}{32}$*d*. This notification underwent various modifications, but in 1904 it was stereotyped into a policy of selling ordinary councils without limit up to 1*s*. $4\frac{1}{8}$*d*. and telegraphic transfers at an analogous rate,* which in effect prevented the rupee rising materially above 1*s*. 4*d*. And in 1905 the supplementary step was taken of diverting, when this seemed expedient, the transfer of gold from Egypt and Australia to India by issuing telegraphic transfers against the deposit of such gold to credit of the India Office in London. This system was convenient as reducing what would otherwise have been an embarrassingly large export of gold to India, while the rates fixed did not preclude the sending out of such gold in considerable quantities. But it was sometimes worked by the India Office in a way that caused much embarrassment to the Government of India by depletion of their rupee stocks, for the Secretary of State's councils had to be met at once, but some time had to elapse before fresh silver could be procured and coined, while, as a matter of fact, new coinage had to be undertaken on a large scale in most years between 1900 and 1914. To tide over this delay in getting silver and coining it, various expedients were adopted, which culminated in 1906 in a portion of the gold standard reserve being held in India, in the shape of 6 crores of coined rupees, to meet emergencies.

As the gold standard reserve was gradually built up from profits of coinage in India, it was transferred to London (save for the silver portion just referred to), at first by actual remittance of gold but subsequently through council drafts by the Secretary of State against the gold standard reserve. The funds thus obtained were invested in Government securities, British and Imperial, so that the reserve might increase by the payment of interest thereon. In 1907 the Secretary of State, on the report of a Committee presided over by Lord Inchcape in connection with Indian railway finance, directed that half the profits of coinage should thereafter be diverted to the financing of capital railway expenses; but this policy met with much opposition and was suspended in 1909. Since then all profits and coinage have continued to accrue to the gold standard reserve.

In 1905 it was decided that the Secretary of State should normally hold in London a portion of the paper currency reserve amounting to about £5,000,000, to be applied when required to the purchase of silver for coinage, so as to facilitate such purchases.

In 1907 and 1908 there was difficulty in connection with the maintenance of the rupee at 1*s*. 4*d*. A world monetary stringency, aggravated by a failure of crops in India which cut down her exports, seriously threatened exchange. The Secretary of State's council drafts had to be suspended, and after a period of what must be frankly described as fumbling by the then Government of India with a quite unfamiliar situation, they resorted to a remedy urged on them by the India Office, and met the position by the issue of what have since been known as reverse councils, viz., the sale in Calcutta of drafts on London at a rate of 1*s*. $3\frac{29}{32}$*d*., representing roughly the 1*s*. 4*d*. standard, less the cost which would have been incurred by actual remittance of gold to maintain it. To meet these drafts, which amounted to about £8,000,000, the Secretary of State had to draw that amount from the gold standard reserve by selling out securities, the amount so drawn being added in rupees to the reserve in India.

* *Per contra*, the Secretary of State refrained in practice from selling councils when he could only do this at less than 1*s*. $3\frac{29}{32}$*d*.

Since then it has been fully realised that conditions threatening to lower the exchange value of the rupee should be primarily met in this way. In all, including drawing by the Secretary of State on the paper currency gold in London and some temporary borrowing in order to make up for the suspension of his council drafts, this crisis caused a drain on sterling resources to the extent of about £18,000,000. The crisis subsided towards the close of 1908, and it was not long before the expansion of Indian trade balances enabled the Secretary of State to replenish the gold standard reserve in London by council drafts against the amounts which had accumulated in India, while fresh rupee coinage was also resumed on a large scale in 1912–14.

This necessarily brief *résumé* will show how far India had travelled during the twenty years subsequent to the closure of the mints. The Government had now the sole responsibility for additions to the rupee coinage, and were forced, always reluctantly, into making such additions on a large scale by the prosperity of India and her demands for currency. During the fifteen years ending with 1913–14 the net absorption of rupees by the public in India, which had to be met in the main by fresh coinage, amounted to about ninety crores, while the note circulation had at the same time risen from about twenty-eight crores to sixty-six. The Secretary of State's council drawings had expanded to supply the demands of trade, and could no longer be confined to what the Government of India could meet from its treasury balances. Large drawings were often made against the paper currency reserve, with the result of setting free rupees from that reserve in India and replacing them by gold in London, which in turn was largely utilised to produce silver for fresh coinage. The gold standard reserve was being constantly added to by the profits on such coinage, and the interest obtained from its investment and, as was recognised in the currency crisis of 1907–8, it was to be utilised in times of adverse exchange in meeting reverse councils. And the sums accruing to this reserve in India, normally through profits on coinage and exceptionally through reverse council sales, were eventually drawn to London by the Secretary of State's council drafts. The paper currency and gold standard reserve were thus intimately connected, and both had holdings in India and England. The normal location of the paper currency reserve was, of course, in India, but, as has been seen, the Secretary of State usually held a sum of about £5,000,000 in London, and this holding was regarded as a first line of defence against exchange troubles. On the other hand, while the normal *habitat* of the gold standard reserve was London, the Government of India held a sum of six crores of rupees as a reserve against sudden demands for silver currency.

At the same time there was a large import of gold into India. Most of the sovereigns and half sovereigns thus imported found their way primarily into the paper currency reserve in exchange for rupees or notes, but a material portion was subsequently absorbed by the public. Thus, in the twelve years ending with March 1913 this absorption for all purposes —melting, hoarding and circulation—amounted to £60,000,000, and in the same period the gold held in the paper currency reserve in India had expanded from £5,750,000 to £19,500,000. These facts are important as showing the extent to which the demand for silver was supplemented by that for gold. As regards the actual use of gold in circulation, after the failure of the 1898 experiment of trying to force this on, the public were left to their own choice, and there was a considerable use of sovereigns in the Bombay Presidency, the Punjab, and the United Provinces, though rather as a substitute for notes than for actual rupees.

In 1913 there was a good deal of criticism, on the whole much more emphatic than well-informed, of the large balances which were accumulating in London through the Secretary of State's heavy council drawings and of the alleged lending out of these at unduly favourable rates to certain London banks; and a Royal Commission was appointed, under the Chairmanship of Mr. Austen Chamberlain, to investigate these matters and inquire into the general working of the currency system. The Commission presented a valuable report in 1914, in which they gave general approval to the system in vogue, and stated at the outset that the establishment of the exchange value of the rupee on a stable basis was of the first importance to India. They indicated, however, various directions in which they thought the time had come for further amendment of procedure. The findings which have special bearing on our subject to-day were as follows: As experience had shown, a gold standard could be obtained without an active gold currency, and it would not be to India's advantage to encourage the use of gold in internal circulation. Rupees and notes were preferable currency *media*, but the people of

India were entitled to such form of currency as they demanded, even though this should be gold. It might be desirable also, mainly for sentimental reasons, that there should be coinage of sovereigns and half sovereigns in India. To meet periods of weak exchange there must be strong gold reserves actual or potential, and no present limit should therefore be placed on the expansion of the gold standard reserve, which should hold a considerable portion of its assets in actual gold, while its silver branch should be abolished. The gold standard reserve should be located in London, and the Government of India should definitely undertake to call it into play when necessary by notifying that they would sell reverse councils at 1*s.* $3\frac{29}{32}$*d.* to the full extent of their resources when asked to do so. The paper currency system should be made more elastic by regulating the fiduciary portion of the paper currency reserve with reference to the actual note circulation, *i.e.* the maximum amount investible should be fixed as a percentage of such circulation, and a commencement should be made in this direction by increasing the existing investment limit of fourteen crores to twenty. The encouragement of the note circulation was a primary necessity, and to this end facilities for encashment should be increased and the Rs. 500 note universalised. The sale of the Secretary of State's council bills should be primarily for the purpose of financing his own requirements, whether for expenditure or in order to transfer to London funds appertaining to the gold standard reserve, or a portion of the paper currency reserve actually or prospectively needed for the purchase of silver. By drafts on this scale reasonable assistance would be given to trade, but it could not claim more than this.

The Commission did not commit themselves on the subject of the supersession of the Indian Presidency Banks by a single State or central bank, which formed the subject of an interesting memorandum by one of the members, Mr. J. M. Keynes, but recommended that this matter should be separately considered later on. And the amalgamation of the Presidency Banks into one great central institution is now about to take place.

Soon after the Commission's report had been published the war broke out, and full consideration of the proposals made had necessarily to be deferred till the skies cleared. And by that time the situation was so materially different that it was necessary to appoint another Committee, whose work we shall come to later on, to deal with the altered state of things.

I now come to the effects which the war had on the currency and exchange system, which it subjected to a period of great and prolonged stress, as to which I can speak with feeling, since it fell to me as Finance Member to deal with the many difficulties of an ever-changing situation. And in tracing the currency history of these years I must necessarily traverse much the same ground as that covered by the first portion of the report of the recent Exchange and Currency Committee.

When the war broke out, India was fortunately in a strong financial position. The treasury balances were high and so were the gold holdings in the paper currency reserve, which amounted in July 1914 to about £12,000,000 in India and £6,000,000 in London. The total assets of the gold standard reserve were over £25,000,000, of which about £5,000,000 were held in gold, besides a considerable amount in short time securities which were about to mature.

The outbreak of war led to a business and exchange panic, which was reflected in a run on Post Office Savings Bank deposits and on the encashment of currency notes. The exchange situation was promptly dealt with by the application of the reverse councils remedy, it being notified that the Government would until further notice sell "reverses" up to £1,000,000 a week, and would support exchange to the full extent of its resources. Provision was at the same time, made for the necessities of immediate remittance by selling telegraphic transfers as well as ordinary bills. Between August 1914 and January 1915 the sale of reverse councils amounted to £8·7 million, to which must be added a further sum of nearly £5,000,000 in the official year 1915–16, when there was a temporary recurrence of exchange weakness; after that there were no exchange difficulties of the old character. The gold standard reserve was strengthened by the abolition of the silver branch, as recommended by the Chamberlain Commission, and the equivalent credit to it of £4,000,000 from the paper currency gold in India, and such gold was also exchanged for the rupees which accrued to the gold standard reserve through the sales of reverse councils. The issue of gold to the public in exchange for notes or rupees was suspended from August 5th, 1914, having been found to result in an undesirable drain which amounted to nearly £2,000,000 in the four days preceding.

The run on the Post Office Savings Banks

depleted their deposits by about 8 crores, or one-third of the total amount, but from 1915–16 the deposits began to increase again. Here, as in the corresponding run on currency notes, the policy adopted was to restore public confidence by giving full facilities for encashment. In fact, in the case of currency notes, the Government took special steps to see that all demands at district treasuries were promptly met, though legally these need only be honoured at currency centres, and steps were taken in the following year to make this policy, as was then hoped, permanent. The run on the currency notes resulted in a decrease of several crores in the circulation. In July 1914 the gross note circulation was about 75½ crores, and the net circulation (deducting the amounts held by Government in its reserve treasuries) about 66¼ crores. In March 1915 these figures had shrunk to about 61½ and 55½ crores respectively, and the old position was not re-attained till July 1916. These drains on the resources of Government, accompanied by stoppage of the Secretary of State's council drawings while exchange was depressed, necessitated a temporary loan of about £7,000,000 from the portion of the gold standard reserve then in India, and a like borrowing through India bills in London, but these sums were ere long repaid. The initial difficulties caused by the war had thus been successfully met, and those which were presently to come upon us were of an entirely different character.

For the five pre-war years ending with 1913–14, Indian trade had been in a very prosperous condition, the excess of merchandise exports over imports amounting on the average to £52,000,000 a year, of which £24,000,000 were met outside the Secretary of State's councils by imports of specie on private account. These thus totalled £120,000,000 for the quinquennium, of which no less than £96,000,000* (on the average about £19,000,000 a year) were in the shape of gold coin and bullion.

During the first two war years Indian trade suffered from the stoppage of relations with enemy countries and other dislocations, and the average excess of exports of merchandise over imports fell to about £31,500,000. But in the three following years the growing demands for Indian products, and the curtailment of imports following on the demands for war purposes on the products of Great Britain and her Allies, brought the average excess of Indian exports over imports to nearly £60,000,000 a year. At the same time the old method of meeting a large part of this balance in the shape of gold had become impracticable, owing to the necessity which the belligerent Governments felt for conserving their gold resources, and in the three years ending 1916–17 the total net imports of gold coin and bullion into India averaged less than £4,000,000 a year, while the private imports of silver for the same period averaged about £2⅔ million only owing to conditions which materially restricted the amounts available for private acquisition. Briefly, these were the falling off of the world's production of silver owing to the anarchic conditions of Mexico, the increased demand for silver coinage set up by the war in various countries, and the consequent rise in price. The result was that the burden of defraying India's trade balances fell more and more heavily on the Secretary of State's council drawings, while the absorption of rupees thus set up was enhanced by the fact that, as the war went on, India was taking an ever-increasing share in financing outlay for military purposes within her own borders and also outside of them, *e.g.* in Mesopotamia, East Africa and Persia. Of the amounts thus expended between 1914–19, about £240,000,000 in all were recoverable from His Majesty's Government, on whose behalf the outlay had been undertaken, but their repayments were made to the Secretary of State in London, and circumstances precluded his remitting more than a small portion out to India in the shape of silver purchases. Heavy rupee credits had also to be given to facilitate American purchase of Indian produce and other analogous arrangements. A situation was thus reached in which the Indian home balances were very large, while those in India itself were subject to constant strain and diminution, and the Government of India were often at their wits' end to devise means for meeting the liabilities cast upon them. They must indeed have failed to do so but for the fact that their large money disbursements in connection with the war were partly counterbalanced by receipts from local borrowings on a scale which was colossal as compared with the amounts they had formerly looked to obtaining from the Indian money market. About 130 crores of rupees were raised in this way between 1917–19, and though this was primarily for the purpose of paying the war contribution of £100,000,000 which India had proffered to the home Government as a free gift in 1917, the adjustment with

* The sterling figures are calculated at the then prevailing rate of 15 rupees to the £.

them was through the Secretary of State's home transactions so that the immediate loan proceeds were available for Indian purposes. Treasury bills, a new feature of Indian finance introduced in 1917, also fetched a net amount, up to November 1919 of over 65 crores. The resources of the Indian Government had likewise been added to by increases of taxation (though these were primarily for revenue and not for currency purposes) effected in 1916 and 1917, while throughout the war ordinary capital outlay on railways, etc., was limited to what was absolutely necessary.

The factors I have just sketched out did not, of course, come into full play for some time; but by February 1916 it became evident to the Government of India that large purchases of silver for coinage would be required to meet the absorption of rupees that had set in, and which would increase with the demands set up by the special circumstances above indicated. The Secretary of State did his best to give help in this direction, and in 1916–17 and 1917–18 was able to purchase about 200 million ounces in the open market, a figure which exceeded the world production of silver for any year since 1913. This demand on silver naturally caused its price to rise. In 1914 the highest London price had been 27¾*d.* per oz., and 1915 showed much the same result; but by December 1916 the price was up to 37*d.*, and in June 1917 to 40*d.*, a dangerous approximation to the 43*d.* at which the cost of providing new rupees would begin to exceed 1*s.* 4*d.*

The demands for rupees were already necessitating a curtailment in the metallic portion of the paper currency reserve, which was authorised in increasing proportion by a series of temporary enactments, commencing in March 1916 with the application of the Chamberlain Commission recommendation that the fiduciary portion of the reserve should be increased, initially, to twenty crores, and the additional six crores were invested in British Treasury Bills. Further and later investments were also in Treasury Bills as the best equivalent to the gold that was no longer available. By December 1916 the Secretary of State's heavy council drawings to meet trade demands gave rise to serious apprehension on the part of the Government of India, whose rupee holdings in the paper currency reserve were then only fourteen crores, and at our earnest request he gave up the system of unlimited sales at 1*s.* 4¼*d.*, and limited his council drawings week by week to amounts, which in practice varied from 130 down to 120 lakhs, fixed with reference to our rupee resources, the rate at which he sold being 1*s.* 4¼*d.* for immediate telegraphic transfers. This measure met with considerable complaint at the time from trade interests, but was absolutely necessary to avoid inconvertibility, which would have been a most serious disaster for India politically as well as economically, and would have been regarded throughout the country as a repudiation by the Government of its note obligations and as indicating its financial and moral bankruptcy.

This great change made it necessary, in the interests of trade, to restrict applicants for the limited amount of councils available to an approved list, which included the exchange banks and some other large purchasers, and to require the grantees of councils to do exchange business with other parties at prescribed rates, and to apply their resources preferentially to the export from India of notified articles of material importance in connection with the war. The exchange banks were at the same time encouraged to finance exports as freely as possible by a guarantee that they would be protected against any possible future loss through the vicissitudes of exchange in respect of the funds they employed, while appeal was made to the mercantile community in India to effect their purchases of sterling through these banks.

In August 1917 the rising price of silver, which had now reached 46*d.* per oz., rendered it necessary to cut loose the rupee from its now traditional 1*s.* 4*d.* mooring, and to raise the price of the Secretary of State's councils to 1*s.* 5*d.* for telegraphic transfers, a figure which had to be further raised to 1*s.* 6*d.* in April 1918 when the silver price per ounce had, under agreement with the American Government, been temporarily stabilised at a dollar. It was announced at the time of the first increase that thereafter the rates at which councils would be sold must be based roughly on the price at which silver could be bought. These steps met with some criticism in India, it being argued, quite wrongly, that they were in contravention of the policy enunciated by the Chamberlain Commission, which had never contemplated a state of things in respect of silver prices such as had now arisen, and that they would play havoc with India's trade. This last prophecy was speedily falsified by events, the fact being that the demand for India's exports was so great that it more than counterbalanced the normal effects of a high exchange, while it was clearly impossible to go on coining rupees at a loss, to stereotype a

situation in which it would become profitable to export rupees from India, or to apply the gold standard reserve, as the critics proposed, to a state of things which it was never intended to meet and which would have completely exhausted its resources. The Government of India and the Secretary of State took these steps with great reluctance, and it is obvious to all who have studied the situation impartially that had exchange been left to unfettered private demand the rupee would have soared to a much higher pitch. The effects of Government control were to keep it down as long as possible.

Meanwhile the absorption of rupees was continuing, and in the summer of 1917 the Government of India addressed a strong representation to the Secretary of State, pointing out that we should drift into inconvertibility if special measures were not taken to avert this calamity. We asked for special gold assistance from His Majesty's Treasury, but this they were not able to afford, and we suggested that steps should be taken to get America to save the situation by the release of part of the large silver reserves stored in her currency vaults. The latter policy was accepted, but negotiations with the United States Government took time and did not finally mature till April 1918, when, thanks to the representations of Lord Reading, most ably seconded by my old friend and former coadjutor in India, Sir James Brunyate, a measure was passed (the Pittman Act) authorising the sale by America to other Governments of up to 350,000,000 silver dollars from the holdings in her reserves. Of this no less than 200,000,000 dollars were allotted to India at a price of 101½ cents per fine oz., which we eventually paid for, partly through the large amount due to us for war expenditure by the British Government, and partly by rupee credits in favour of the Federal Reserve Bank of New York for the financing of American purchases in India. This most welcome supply eventually saved the situation, but in the interim we were in a very parlous state, as the American dollar silver did not begin to come in till July 1918. Meanwhile we had been taking such measures as we could to strengthen our precarious position. In the early part of 1917 we sold gold bullion in India to the value of about £4,000,000, and subsequently released five million sovereigns for the financing of crops, chiefly in the Punjab and Bombay. The difficulty in utilising gold as a substitute for rupees was, however, that as there had been hardly any supplies of gold to the Indian public since the commencement of the war, the sovereign had acquired a scarcity premium materially above its standard ratio of rupees 15. We prepared however, to add to our stock of gold, against future emergencies, by an Ordinance, issued in June 1917, requiring all gold imported into India to be sold to Government at a price based on the exchange value of the rupee. By this means we obtained the greater part of the gold imports of 1917–18, which amounted in all to over £14,000,000, and came in from Japan and America by reason of the difficulties those countries had of obtaining rupee exchange. But in the following year the import came to a standstill owing to restrictions placed on the export of gold from the United States. About the same time we declared the use of silver and gold coins for other than currency purposes to be illegal, though the prohibition was one very difficult to enforce; and in September 1917 we prohibited the import of silver into India on private account as tending to interfere with the Secretary of State's purchases, and declared the export of silver coin and bullion illegal, to guard against the temptation to such export through the bullion value of the rupee exceeding at any time the exchange value. Further, in December 1917 and January 1918, we issued small notes of the value of Rs. 2½ and 1 respectively with the hope that the use of these would diminish the demand for rupees. This experiment did not at first meet with rapid success, but in little more than a year the circulation of these notes (chiefly in the R. 1 issue) exceeded twelve crores.

We continued to economise our rupee holdings by larger investments in the paper currency reserve; but in spite of all these expedients our silver balances had fallen in March 1918 to less than 10½ crores, a figure which would have been considered absolutely unsafe before the war. Then bad news from the Western Front led to a run on notes. By the end of April we had only 7½ crores of silver left, and in the first week in June no more than four. Inconvertibility seemed inevitable, but we did all that was possible to avert it, sending, for instance, a war vessel to Hong Kong to bring over from there a considerable amount of silver which the Secretary of State had procured for us from America. We withdrew most of the facilities previously granted for the encashment of notes at district treasuries and reverted to our former legal obligation to meet these at currency centres only, while to relieve the pressure there we prohibited the transport of specie on private account by rail or steamer, or its transmission

through the post. As the recent Committee justly observe, the result of these restrictions was the substitution of notes for rupees to a large extent as a currency medium, and by November 1919 the note circulation had risen to nearly 180 crores. We obtained the sanction of the home Government to the establishment of a branch of the Royal Mint at Bombay for the coinage of sovereigns, so as to be able to utilise our gold bullion instead of having to send this to Australia to be coined, and pending its establishment (in August 1918) we used our own mints to turn out a local gold piece of the value of Rs. 15, styled a gold mohur, which one of my colleagues facetiously corrupted into "the gold Meyer." And during the spring of 1918 we issued sovereigns and mohurs to the extent of nearly £6,000,000 for the financing of crops, mainly in the Punjab. These issues did not remain in circulation, the scarcity value of the gold coins being now so large as to induce the recipients to hoard or melt them; but the measure achieved its immediate object, which was to gain time by diminishing the strain on our scanty silver stocks.

From July 1918 the position mended with the arrival of silver from America, and the total importation for the year 1918–19 amounted to about 106,000,000 ounces obtained by the Secretary of State, and over 150,000,000 ounces from the Pittman dollars (the remainder of these arrived in the following year). But although we had just escaped inconvertibility, it took some time before we were in an assured position, and I used anxiously to scan weekly returns of the steamers under way, the amounts of silver they were carrying, and the dates on which they might be expected to arrive. When I quitted office in November 1918 our silver stocks in the paper currency reserve—which by an Ordinance passed in the previous April could be made to include all silver held for us in America or in transit thence—amounted to about 10½ crores of coined rupees and 19½ crores of bullion, while by November 1919 the silver stocks amounted in all to about 47½ crores.

Subsequent difficulties have been mainly in connection with the ever-increasing price of silver. We have already seen that in April 1918 the exchange value of the rupee had had to be raised to 1*s.* 6*d.* For about a year after that silver prices remained fairly constant, owing to strict control over private exports by the United States Government and Canada, and the fixation by the British Government of a maximum price which followed the American one of 101½ cents per ounce. But in May 1919 these controls were withdrawn, and the price of silver at once soared, pushed on by heavy demand from China, and necessitating an exchange rate of 1*s.* 8*d.* Another important factor now came into play. The basic silver values are dictated by the conditions of the American market and the dollar prices quoted there, while as the bulk of India's exchange transactions are through London, and the silver she requires for coinage has to be purchased by the Secretary of State, the dominant factor here is the London sterling price. In normal conditions, however, this distinction is of no practical importance, and until after the close of the war special measures were taken by His Majesty's Government to maintain sterling-dollar exchange at almost its full normality. But in May 1919 it was decided that such special control was no longer necessary, and that the course of Anglo-American exchange should be left to natural conditions. The heavy debts due to America from Europe, for which Great Britain is to a large extent an exchange clearing-house, and the impossibility in present conditions of meeting the demands for American products by counter-exports, caused the exchange to fall rapidly against sterling. In normal times the pound is worth about $4.87. In December 1919 it only fetched $3.83, and at the time I write it is about $3.67, having previously been lower still. These circumstances led to the sterling price of silver being materially in excess of the gold-dollar value and to a rapidly increasing rupee exchange. In August 1919 the Secretary of State had to fix this minimum rate for immediate telegraphic transfers at 1*s.* 10*d.*; in September, at 2*s.*; in November, at 2*s.* 2*d.*; and in December, at 2*s.* 4*d.*

Fortunately, it was not necessary to purchase fresh silver on behalf of India during these months, as she became once more able to acquire gold. In June 1919 the American Government removed its previous embargo on gold exports, and His Majesty's Treasury, which had been very nervous during the war as to a drain of gold by India, now consented to the Secretary of State acquiring what he could for the Indian Government. Between August and November 1919 some 467,000 fine ounces (an ounce would produce 4¼ sovereigns) were obtained in New York by temporary sales there of telegraphic transfers on India to provide rupees required for the financing of American trade; about 2,500,000 ounces were purchased by the Secretary of State in London, the United States and

Australia; and private imports, which were encouraged by notifying that the Government would take them over at a price which made allowance for the difference between gold and sterling values, brought in nearly 350,000 ounces. The last paper currency return I have available shows that this includes, against a gross circulation of 183 crores, silver coin and bullion to the value of 39 crores and about £30,500,000 in gold, actually in India or in transit thereto.

Efforts have been made to pass some of the gold acquired into the possession of the public in India and thereby to diminish the previous scarcity value of the sovereign. Since September last there have been fortnightly sales of gold bullion, the amount sold up to the end of November being the equivalent of about 3½ million sovereigns, and these sales, which still continue, have materially reduced the premium in question.

I may note here that after the conclusion of the war it was no longer necessary to take special measures for the financing of particular Indian products from the Secretary of State's council sales, or to confine these to a limited number of approved bidders. The old system was therefore reverted to, with the important modification that the total weekly sales continued to be limited to what the Government of India could conveniently meet from time to time, while a limit was also placed on the amount which could be applied for by any one applicant.

(*To be continued.*)

GENERAL NOTES.

Sericulture in France during 1919.—According to an official statement recently published by the *Office des Renseignements Agricoles*, the rearing of the silkworm in the nineteen Departments where this industry was carried on occupied no fewer than 52,401 persons. The quantity of "grain" (silkworms' eggs) incubated was 65,983 lots of 25 grams (nearly an ounce) each, of which 63,277 lots were of French, and 2,676 lots of foreign origin. The total production amounted to 2,671,623 kilogs of cocoons (*cocons frais*), that is to say live ones. This gives an average of about 40½ kils., or about 88 lb. per ounce of 25 grams of seed hatched. The average price per kilog of cocoons was 7·53 francs for cocoons for spinning and 7·85 francs for reproduction of eggs. The total amount realised by sale of cocoons was 20,121,402 francs.

National Thrift.—The House of Commons has passed the second reading of a Government Bill to withdraw all restrictions made in the Act governing savings and trustees savings banks in respect to the limits applicable to depositors and holders of stock. Hitherto deposits have been limited to £50 in one year and a total sum of £200. In the case of investments in Government stock the respective limits have been £200 and £500. The special war regulation removing the limit on deposits ceases to have effect within six months after the end of the war. The Bill also provides for the changing of the name of the "War Saving Certificates" to "National Savings Certificates," and sanctions an increase in the allowance.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday afternoons, at 4.30 p.m.:—

May 5.—Dr. C. E. Kenneth Mees, "A Photographic Research Laboratory." Sir Henry Trueman Wood, Chairman of the Council, will preside.

May 12.—Graily Hewitt, "Rolls of Honour." Halsey Ricardo, F.R.I.B.A., will preside.

May 19.—John Somerville Highfield, M.Inst.C.E., M.I.E.E., "Electrical Osmosis." Alan A. Campbell Swinton, F.R.S., will preside.

Indian Section.

Thursday afternoon, at 4.30 p.m.:—

May 20.—Brigadier-General Lord Montagu of Beaulieu, K.C.I.E., C.S.I., "Roads and Transport in India."

Monday afternoon, at 4.30 p.m.:—

May 31.—Albert Howard, C.I.E., M.A., A.R.C.S., F.L.S., Imperial Economic Botanist to the Government of India, "The Improvement of Crop Production in India." Sir Robert W. Carlyle, K.C.S.I., C.I.E., will preside.

Friday afternoon, at 4.30 p.m.:—

June 18.—Sir Valentine Chirol, "The Enduring Power of Hinduism." (Sir George Birdwood Memorial Lecture.)

Indian and Colonial Sections.

(Joint Meetings.)

Friday afternoons, at 4.30 p.m.:—

May 28.—Professor William A. Bone, D.Sc., Ph.D., F.R.S., "Lignite."

June 4.—Professor Sir John Cadman, K.C.M.G., D.Sc., F.G.S., M.Inst.C.E., "The Oil Resources of the British Empire."

Cantor Lectures.

Monday evenings, at 8 p.m.:—

Arthur Thomas Bolton, F.R.I.B.A., F.S.A., Curator, Soane Museum, "The Decoration and

Architecture of Robert Adam and Sir John Soane, 1758–1837." Three Lectures.

Syllabus.

LECTURE I.—MAY 3.—The first lecture deals with the general position in English architecture at the time of Robert Adam's return from Italy in 1758, and describes the revolution of taste that he brought about. The leading ideas of his scheme of architecture and decoration, now known as the Adam style, are fully discussed.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MAY 3 ... ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. A. T. Bolton, "The Decoration and Architecture of Robert Adam and Sir John Soane, 1758-1837." (Lecture I.)

Farmers' Club, at the Surveyors' Institution, 12, Great George-street, S.W., 4 p.m. Professor D. A. Gilchrist, "Best Methods of Laying Down and Improving Grass Land."

Royal Institution, Albemarle-street, W., 5 p.m. General Monthly Meeting.

Engineers, Society of, at the Geological Society, Burlington House, W., 5.30 p.m. Mr. W. G. Cooke, "The Assessment of Engineering Undertakings."

Chemical Industry, Society of (London Section), at the Chemical Society, Burlington House, W., 8 p.m. 1. Messrs. F. G. Donnan and J. I. Orme Masson, "The Theory of Gas-Scrubbing Towers with Internal Packing." 2. Messrs. P. F. Frankland and A. F. Garner, "The Preparation of Picryl Chloride." 3. Messrs. P. F. Frankland, F. Challenger, and Miss D. Webster, "The Preparation of Thiocarbonyl Tetrachloride."

Geographical Society, 135, New Bond-street, W., 8.30 p.m. Mr. H. St. J. Philby, "Across Arabia: from the Persian Gulf to the Red Sea."

TUESDAY, MAY 4 ... League of Nations Union, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 6.30 p.m.

Anglo-Russian Literary Society, Imperial Institute, South Kensington, S.W., 3 p.m. Mr. W. B. Steveni, "The Republics of Old Russia."

Royal Institution, Albemarle-street, W., 3 p.m. Professor A. Keith, "British Ethnology—The Invaders of England." (Lecture II.)

Alpine Club, 23, Savile-row, W., 8.30 p.m.

Röentgen Society, at the Medical Society, Chandos-street, W., 8.15 p.m. Professor S. Russ, "Some Problems in the Action of Radiation upon Tissue."

WEDNESDAY, MAY 5 ... ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Dr. C. E. Kenneth Mees, "A Photographic Research Laboratory."

British Academy, at the Royal Society, Burlington House, W., 5 p.m. Sir Reginald Blomfield, "The Tangled Skein: Art in England, 1800 to 1920."

Geological Society, Burlington House, W., 5.30 p.m.

Public Analysts, Society of, at the Chemical Society, Burlington House, W., 8 p.m. 1. Mr. C. A. Mitchell, "Estimation of the Age of Ink in Writing." 2. Mr. E. R. Dovey, "Estimation of Chinese Crude Camphor." 3. Messrs. H. D. Richmond and L. R. Ellison, "Studies in Steam Distillation, Part 7: The Volatility of Isomers."

Automobile Engineers, Institution of, at the Institution of Mechanical Engineers, Storey's-gate, S.W., 8 p.m. Major B. H. Thomas, "Electro Deposition of Iron as applied to Motor Vehicle Repair Work."

Royal Archæological Institute, at the Society of Antiquaries, Burlington House, W., 4.30 p.m. Mr. A. Vallance, "Figure Sculpture, Painted Glass, and Mediæval Decoration."

University of London, at the School of Oriental Studies, Finsbury-circus, E.C., 5 p.m. Mr. A. Safwat, "Bahaism."

THURSDAY, MAY 6...Post Office Engineers, Institution of, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.45 p.m.

University of London, at the School of Oriental Studies, Finsbury-circus, E.C., 6 p.m. Dr. S. Ahmad Khan, "The Development of Modern Educational Institutions in India." (Lecture I.)

Royal Society, Burlington House, W., 4.30 p.m.

Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Linnean Society, Burlington House, W., 5 p.m. 1. Dr. G. P. Bidder, (*a*) "Notes on the Physiology of Sponges"; (*b*) "*Pandorina spongiarum*, a new species of Alga found in a Sponge." 2. Mr. E. J. Bedford, "The British Marsh Orchids and their Varieties, illustrated by coloured drawings and lantern-slides."

Chemical Society, Burlington House, W., 8 p.m. 1. Mr. G. M. Bennett, "The mustard-gas problem." 2. Mr. C. K. Ingold, "A new method of preparing muconic acid." 3. Messrs. J. W. Cook and O. L. Brady, "The dinitration of *m*-acetotoluidide." 4. Messrs. Y. Venkataramayya and M. V. Narasimhaswamy, "A new ozonizer." 5. Messrs. G. T. Morgan and H. D. K. Drew, "Orthochlorodinitrotoluenes." (Part I.)

Royal Institution, Albemarle-street, W., 3 p.m. Mr. R. C. Thompson, "The Legends of the Babylonians." (Lecture II.)

Iron and Steel Institute, at the Institution of Civil Engineers, Great George-street, S.W., 10 a.m. 1. Annual Meeting. 2. Inaugural Address by the President. 3. Mr. E. H. Lewis, "Iron Portland Cement."

2.30 p.m. 1. Mr. F. Clements, "British Blast Furnace Practice." 2. Mr. H. E. Wright, "Chemical and Thermal Conditions in Blast Furnace Practice." 3. Mr. C. H. Ridsdale, "The Valuation of Ores and Iron Making Material." 4. Mr. J. A. Heskett, "The Utilisation of Titaniferous Iron Ore in New Zealand."

FRIDAY, MAY 7...Anglo-Batavian Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.45 p.m.

Iron and Steel Institute, at the Institution of Civil Engineers, Great George-street, S.W., 10 a.m. 1. Mr. C. A. Ablett, "Direct Current compared with Three-Phase Current for Driving Steel Works Plant." 2. Mr. J. F. Wilson, "Notes on Slag Conditions in Open-Hearth Basic Steelmaking Practice." 3. Messrs. B. Yaneske and G. A. Wood, "The Reduction of Silicon from the Slag in the Acid Open-Hearth Process."

2.30 p.m. 1. Mr. W. E. Hughes, "Some Defects in Electro-deposited Iron." 2. Messrs. T. Baker and T. F. Russell, "Note on the Ball Test." 3. Mr. J. H. Whiteley, "The Distribution of Phosphorus in Steel between points Ac1 and Ac3." 4. Mr. G. F. Preston, "Practical Notes on the Design and Treatment of Steel Castings."

Royal Institution, Albemarle-street, W., 9 p.m. Lord Rayleigh, "The Blue Sky and the Optical Properties of Air."

Philological Society, University College, W.C. 8 p.m. Anniversary Meeting.

China Society, at the School of Oriental Studies, Finsbury-circus, E.C., 5.30 p.m. Mr. G. S. Boulger, "The History of Silk."

SATURDAY, MAY 8...Royal Institution, Albemarle-street, W., 3 p.m. Dr. F. Chamberlain, "The Private Character of Queen Elizabeth." (Lecture II.)

Journal of the Royal Society of Arts.

No. 3,520. VOL. LXVIII.

FRIDAY, MAY 7, 1920.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

MONDAY, MAY 10th, at 8 p.m. (Cantor Lecture.) ARTHUR THOMAS BOLTON, F.R.I.B.A., F.S.A., Curator, Soane Museum, "The Decoration and Architecture of Robert Adam and Sir John Soane, 1758-1837." (Lecture II.)

WEDNESDAY, MAY 12th, at 4.30 p.m. (Ordinary Meeting.) GRAILY HEWITT, "Rolls of Honour." HALSEY RICARDO, F.R.I.B.A., will preside.

Further particulars of the Society's meetings will be found at the end of this number.

CANTOR LECTURE.

On Monday evening, May 3rd, Mr. ARTHUR THOMAS BOLTON, F.R.I.B.A., F.S.A., Curator, Soane Museum, delivered the first lecture of his course on "The Decoration and Architecture of Robert Adam and Sir John Soane, 1758-1837."

The lectures will be published in the *Journal* during the summer recess.

NINETEENTH ORDINARY MEETING.

WEDNESDAY, MAY 5th; SIR HENRY TRUEMAN WOOD, Vice-President and Chairman of the Council of the Society, in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Bixby, William Keeney, M.A., LL.D., St. Louis, Missouri, U.S.A.
Bowden, John, Chorlton-cum-Hardy, Manchester.
Christie, Edward William, London.
Cleveland-Stevens, Edward Carnegie, M.A., D.Sc. (Econ.), London.
Cravath, Paul D., A.M., LL.B., New York City, U.S.A.
Davies, Thomas Bertram, Durban, Natal, South Africa.
Grieve, Norman William, London.
Gross, Alexander, F.R.G.S., London.
Kerr, Henry Farquharson, New York City, U.S.A.
Norrington, George Frederick, Wilmslow, Cheshire.
Perry, Mrs. Thos. Sergeant, Boston, Mass., U.S.A.
Reed, Harry E., Swansea.
Richards, Captain James Charles, Assoc.Inst.N.A., Bombay, India.
Summers, Albert Victor, Cheadle Hulme, Cheshire.
Thomas, David Idwal, M.Inst.M.E., Porth, Wales.

The following candidates were balloted for and duly elected Fellows of the Society:—

Birrell, William, Loughborough.
Dobbs, Ernest John, Birmingham.
Walker, W. Ralph, J.P., Lochgilphead, Argyll.

A paper on "A Photographic Research Laboratory" was read by Dr. C. E. KENNETH MEES.

The paper and discussion will be published in a subsequent number of the *Journal*.

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

THE INDIAN CURRENCY SYSTEM AND ITS DEVELOPMENTS.

By SIR WILLIAM MEYER, G.C.I.E., K.C.S.I.

(*Continued from page* 393.)

The bewildering sequences of events which I have endeavoured to summarise led to the appointment by the Secretary of State, with the full concurrence of the Government of India, of a very strong Committee on Indian Exchange and Currency, to provide, if possible, definite principles and lines of action for the future in place of the hand-to-mouth expedients which the ever-changing circumstances of the war and its aftermath had hitherto dictated; in short to endeavour to revise the doctrines of the Fowler Committee with reference to the circumstances of a new era in which high and not low prices of silver were the predominating feature. As

stated in the concluding portion of the terms of reference, the primary necessity was to fix on "the policy that should be pursued with a view to meeting the requirements of trade, to maintaining a satisfactory monetary circulation, and to ensuring a stable gold exchange standard." The terms of reference did not include any allusion to the possibility of international bimetallism, the consideration of which would have been quite impracticable at a time when the world's exchanges are in their present chaotic condition.

This Committee, which was presided over by Sir Henry Babington Smith, and of which our Chairman of to-day was *pars magna*, was appointed in May 1919 and reported just before Christmas. The report, which gives a most able and lucid presentment of the difficulties which have arisen and the policy necessary for the future, and which has received the full approval of the Secretary of State as regards the measures immediately necessary, provides what I think is the best policy possible in present conditions, and will always be a classic in the literature of Indian currency. Many of you have, of course, read it, but for the benefit of those who have not, and to refresh the memory of those who have, I propose to give a fairly full abstract of its findings. I may say here, and I am sure our Chairman will agree with me, that I think the Committee were greatly assisted in coming to their final conclusions by the rapid march of events while they were sitting, culminating, as has already been mentioned, in the advance of rupee exchange up to 2*s.* 4*d.*, and the demonstration that large gold supplies were once more obtainable for India.

A most important document which the Committee found before them when they assembled was a memorandum on future policy prepared by the Government of India not long before. In this document the Government of India laid preponderant stress on the necessity, in the interests of trade, of obtaining a reversion to stability of exchange, and of terminating a situation in which this was at the mercy of spasmodic increases necessitated by the progress of silver prices. They aimed, therefore, at obtaining a permanent rate of exchange at a figure which they left it to the Committee to fix, though it seems clear that they hoped that this would not materially exceed the 1*s.* 8*d.* rate which had then been lately notified; and they proposed that should the price of silver rise to a level which would render the further supply of rupees a matter of loss with reference to the stabilised rate, the Secretary of State should abstain from further purchases, a measure which it was hoped would bring silver down again. At the same time the Secretary of State was to revert to the old system of selling councils without limit to meet the demands of trade. The Government of India recognised that heavy council drawings, combined with a shortage or stoppage of silver supplies, might speedily exhaust their rupee stocks. (They admitted the desirability of enhancing their gold reserve, but evidently did not contemplate a situation in which large supplies of this metal would be available, while in any case they deprecated the use of gold for circulation.) These factors would obviously provoke inconvertibility, which in my time the Government of India had regarded as one of the worst calamities, politically as well as economically, which could befall the country. My distinguished successor, Lord Meston, took a different view, however, and while admitting that inconvertibility would be a serious matter, thought that it ought to be faced if necessary, now that the war was over, in order to secure exchange stability, and comforted himself with the hope that it need only be of short duration if the stoppage of purchases for the Government of India reduced silver prices again. I said at the commencement of this paper that I proposed to abstain from polemical disquisitions, otherwise I should have been tempted to use strong language about what I regard as a most dangerous policy. But I had an opportunity of telling the Committee what I thought of it when I appeared before them as a witness, and I was very pleased to see that in paragraph 41 of their report they condemn the proposal in restrained but emphatic terms. Taking the case merely from the currency point of view, they observe that "the credit of the Government would suffer a severe blow, and if belief in the convertibility of the note were once shaken it might take many years of anxious labour to restore confidence, while the set-back to development of a sound and economical monetary circulation in India would be disastrous."

They were justly sceptical of the Government of India's view that the cessation of the Secretary of State's silver purchases would bring down the price, observing that he had stood out of the silver market in the latter part of 1919 when he could afford to do so by reason of the stocks then in India, but that other demands had nevertheless greatly enhanced prices. They also observed, with reference to an alter-

native suggestion of "partial inconvertibility," under which the encashment of notes at currency centres would be subject to such conditions in respect of amount, etc., as the Government of India might prescribe, that the effect of this on the credit of Government and on popular confidence in the note issue would differ but little from inconvertibility pure and simple. The Committee arrive, therefore, at the (to my mind) most satisfactory *dictum* that "the maintenance of the convertibility of the note issue is a vital part of the India currency system."

The action of the Government of India in this connection has an interesting parallel in that of Sir James Westland in 1898, to which I referred in a previous part of this paper, as regards lowering the exchange standard to 1*s*. 3*d*. and the melting down of the rupee. In both cases the authorities in India gave way to counsels of despair just at a time when events were to prove these unnecessary—in the present instance through the resumption of large gold supplies.

I have dealt with this matter, by reason of its primary importance, a little out of its place in the Committee's findings, but as regards the rest of these I shall follow as far as possible the order in which they are presented in the report from paragraph 33 onwards. The Committee start by recording that the system built up since 1893 worked well and was beneficial to India. Its failure to meet recent circumstances was due to a rise in the price of silver that could not have been foreseen.

As regards stability of exchange, to which the Government of India attached such overwhelming importance, the Committee find (para. 34) that "for the current operations of trade stability is an important facility rather than an essential condition"; and they go on to say (paras. 35 and 36) that "whatever the evils and inconveniences of instability may be, they are increased if the movements of exchange are brought about not by the automatic action of economic causes but by administrative acts," and that the object should therefore be to restore stability to the rupee at as early a date as practicable, and also to restore the automatic working that characterised the Indian currency system in the past." I may note, however, that such full automatic conditions as would result from the re-opening of the mints to free silver coinage are not recommended.

The Committee next consider and condemn, this time in complete accord with the Government of India, a suggestion which has every now and then been made that the exchange value of the rupee might be kept down, without inconvertibility, by the issue of a rupee piece of less bullion value than the present one. As to this they say (para. 38), "the fineness of the present rupee, which is known to every village goldsmith and silversmith, has remained unaltered since 1835, and its use is so firmly rooted in the habits of the Indian people as to have given it the character of a standard weight." Modification of such weight or fineness would "re-act gravely on the credit of the Government, and possibly lead to serious social and economic consequences," while, in accordance with Gresham's law, the old rupees would be driven out of circulation and currency difficulties thus increased. For similar reasons they reject the idea of keeping the rupee on its present footing, but issuing a Rs. 2 or Rs. 3 coin of lower bullion value, or of turning the rupee into a nickel piece, though they fully approve the replacement of silver by nickel in respect of smaller coins.

They then (para. 42) discuss the probability of future variations in the price of silver, and though this is a matter on which prophecy is of course most difficult, they put forward the view that the price per ounce is not likely for some years to come to exceed what would be the equivalent of 2*s*. (gold) per rupee; or to be lower than one dollar, viz., the amount which America will have to pay for the silver which she must procure, under the Pittman Act, to replace the dollars taken from her currency reserve, and which implies a bullion value for the rupee of not less than 1*s*. 6*d*. (gold). They hold therefore that if the exchange value of the rupee is fixed at 2*s*. gold (at present it would, of course, be considerably more than this in sterling) stability can be secured.

They discuss this rate more fully later on, but first make an interesting digression as to the economic effect of a high rate of exchange (paras. 44 to 50). They give reasons for holding that the rise in exchange, so far as it has checked increase of prices in India, has been to the advantage of the country. As regards the effect on Indian trade, they point out (para. 51) that while the primary result of a rise in exchange is to stimulate imports and reduce exports, these results tend to disappear—as shown by experience in connection with the 1*s*. 4*d*. rupee—when wages and other elements of production-cost have adjusted themselves to the new conditions. At present, moreover, the demand for

India's products, and the price levels in the countries which need them, mitigate the effect of high exchange, even at the outset, to the Indian producer, who also benefits by the diminished cost in rupees of the imported stores and machinery he needs. This reasoning is based on the assumption (a fairly safe one for the present) that world prices will remain high for a considerable period, and that any subsequent return to lower levels will be gradual. The Committee admit that if prices were to come down with a rush, the effect of high exchange on Indian exports might be so serious as to necessitate reconsideration of the position.

They also point out (para. 52) that the development of Indian industry is in present conditions not likely to be materially prejudiced by the stimulus that high exchange would normally give to imports, and (para. 53) that there will be a great gain to the Indian community as represented by its Government on the home charges.

The Committee then revert to the way in which stability of exchange is to be sought, a problem rendered difficult by the present divorce between the gold and sterling values of silver as of other commodities, and the concomitant depreciation of sterling currency as compared with the American dollar which rests on a gold basis. They had already, as we have seen, come to the conclusion that the rupee could be stabilised at a figure representing 2*s.* in gold, and the problem then was whether to take this as the open basis or to fix the stable figure at some corresponding amount in sterling (paras. 55–57). The latter plan would have the advantage of a less open breach with the past, and would conform to the fact that Indian exchange, for which London is the clearing-house, must in any case translate itself into sterling figures. But a stable sterling rate would be practically impossible to obtain in present circumstances, with the sterling ratio to gold constantly varying, save by its fixation at a figure which would prove undesirably high when in the future sterling and gold come together again. To adopt a fixed sterling basis would also, at present, make it impossible to establish a permanent ratio between gold and silver in India; their relations would have to fluctuate with the vagaries of gold-sterling exchange, and it would be impossible to initiate a system of automatic import and coinage of gold. The Committee, therefore, come to the conclusion that the balance of advantage lies in fixing the stable exchange value of the rupee at 2*s.* gold, which the future will also convert into a like sterling figure. I think this was the best solution they could have come to, but it means, of course, that while sterling and gold remain separate, sterling exchange quotations must be liable to constant variation. The stability is in the depths and not on the surface, and one can only hope that the position will be simplified ere long by the return of sterling and gold to their old happy union.

The practical application of these considerations is illustrated by the fact that when the Secretary of State accepted the Committee's proposal, he had to take as the then sterling equivalent of a 2*s.* (gold) rupee a sum of about 2*s.* 9*d.*, a rise of 5*d.* over the exchange rate which had been notified on December 12th last. (There has been material reduction since, with recovery of sterling values.) It is a pity in one way that the 2*s.* 4*d.* rate had not been allowed to rise higher before the new system was applied, for the sudden increase of 5*d.* per rupee temporarily disorganised trade and has been followed by a cessation of applications for the Secretary of State's councils and by a demand for "reverses" in India, the sales of which up to the beginning of March amounted to about £18,000,000 at rates which follow gold prices as led up to by the sterling-dollar exchange figures, less a deduction (taken at $\frac{3}{8}d.$) representing what would have been the expense of transmitting gold home. The Secretary of State's minimum sale prices, with reference to which he will call for tenders, will be analogously based on the cost at sterling rates of procuring gold and sending it to India. The Secretary of State has hitherto been able to meet these reverse councils out of his treasury balances, which had been swollen through repayment by His Majesty's Government of war charges due by them to India, but it has now become necessary to indent on reserves; and the first step taken will probably be to find the sterling required for payment of continued "reverses" by liquidation of some of the British Treasury Bills at present held in the paper currency reserve, a corresponding cancellation of notes being effected in India. The cessation of applications for the Secretary of State's bills has been caused by a large net demand for remittance *from* India, primarily to take advantage of hitherto undreamed of exchange rates. In time, of course, the situation will right itself, assisted, it may be hoped, by continued improvement in sterling values; and demand will once more arise, stimulated by a large surplus of Indian exports over imports, for currency in India, which will restore applications for

councils. But at the outset the new system has started in heavy waters. It will be remembered, however, that the establishment of the rupee at 1*s*. 4*d*. also took time and trouble, and the Committee gave good reasons (para. 58) against deferring action, a course which would have continued and aggravated the former uncertainties. To put the matter in a nutshell, in present circumstances a stable *sterling* exchange was impossible except at the cost of inconvertibility, or debasement of the rupee, which would be far too heavy a price to pay for it, and we must be content with having got to a stable gold point, to which sterling will also conform when normal conditions are re-established.

As regards the future adequacy of the 2*s*. gold rate, if silver should subsequently fall it would be as easy to keep the rupee above its bullion value as in the days of the 1*s*. 4*d*. standard; but it would be a much more serious matter if the price should rise to a figure which would make the rupee bullion value exceed 2*s*. (gold). The Committee advise (para. 59) that such a situation should be met *not* by a policy of inconvertibility, but by reducing the sales of councils, abstaining as far as possible from silver purchases, and promoting the use of gold. And it would be better in their view to coin rupees, if necessary, at a loss than to tamper with the 2*s*. gold standard. It seems to me, however, that these remedies could not hold good against a high and long-continued rise in silver; that would require a re-investigation of the whole position, just as past rises have broken down the old 1*s*. 4*d*. standard. But sufficient unto the day is the evil (or good) thereof, and we may hope that the new policy will at any rate have as long a spell of life as the old one. Moreover, by the time that matters may need reconsideration, India should have progressed materially in the direction of self-government, and the new policy could be considered by her legislature.

As regards future council sales, the Committee (para. 61) give complete adherence to the Chamberlain Commission's *dictum* that the primary object of the Secretary of State's council bills is not the convenience of trade but to put him in funds for his various requirements. But he may, on occasion, when this can conveniently be done and will not affect the normal location of the paper currency and gold standard reserves which is subsequently discussed, sell supplementary drafts to meet trade requirements and prevent undue accumulation of gold in India. So long, however, as present difficulties in respect of supply of silver for coinage continue, weekly sales of councils should be limited to the Secretary of State's requirements and the capacity of the Government of India to meet these. While sterling and gold remain apart, the minimum sterling rates at which the Secretary of State will offer his bills to competition must vary, being based, as above observed, on the sterling cost at any given date of obtaining gold and sending it to India; but when sterling and gold come together again the minimum rate will be uniform.

The Committee also endorse (para. 62) the Chamberlain Commission's recommendation that whenever there is a demand for these, the Government of India should, on their own motion, and without requiring sanction by the Secretary of State, sell reverse councils freely, and as has been seen they are doing this largely at present. Here, too, the sterling rates for "reverses" must at present vary according to the gold-sterling ratio.

As regards India's demand for the precious metals, the Committee (paras. 63–4) hold that previous gold imports have not been excessive having regard to the population and its needs, and that India is entitled to obtain payment for her products in the form most acceptable to her people. They trust, however, that the development of industrial enterprise and increased facilities for the investment of savings will lead to a diminution of the demands for specie. In this connection they welcome (para. 73) the coming amalgamation of the Presidency Banks, which is to be followed up by the opening of at least a hundred new branches in the next five years, and hold that the people should be more fully encouraged to make interest-bearing investments in Post Office Savings Banks and co-operative credit societies. Also that all possible facilities should be given for small investors to take part in the Government loans, to which end a post office section should be part of the normal borrowing system. That is a policy which I developed as Finance Member, and I am delighted to find the Committee endorsing it so fully.

As regards the private import of gold, this should normally be free (para. 65); but the present power of acquisition by Government should be retained till the new ratio between the rupee and the sovereign in internal circulation, which the Committee recommend, has been effected. That ratio has hitherto been fixed by law at fifteen to one; but obviously the fixing

of the exchange value of the rupee at 2*s.* (gold) requires a similar ratio within India itself, and the law should be amended accordingly (para. 69). This cannot, however, be done, as the Secretary of State has recognised, till the continued sale of gold bullion has caused the permanent disappearance of the scarcity premium of the sovereign over Rs. 15. When that position is arrived at it will be necessary to notify that sovereigns and half sovereigns, which have hitherto been unlimited legal tender at Rs. 15 and Rs. 7½ respectively, will be valued at Rs. 10 and Rs. 5, a short period being allowed for holders of existing coins to convert these into rupees at the old rates. The gold mohurs, which were issued at Rs. 15, should also be redeemed at that figure, and the mohur should then be demonetized.

As regards the use of gold in internal currency, the Committee agree (para. 66) with the Chamberlain Commission that the people of India are entitled to such currency as they prefer, but that the use of notes and rupees is preferable to that of gold. While, however, there is difficulty in meeting the full currency demands for silver, gold should be issued to safeguard the note issue, and to prevent such gold issues being looked on as a special measure indicating that the Government is in difficulties there should be regular normal issues to a moderate amount.

To buttress the gold currency it is desirable that an Indian branch of the Royal Mint, such as was established in 1918, but closed in the following year owing to difficulties in supplying the necessary staff, should be opened for coinage of sovereigns, on tender by the public of gold bullion at the rate (subject to a small seigniorage charge) of 113 grains of fine gold per sovereign, corresponding to the 2*s.* gold point in respect of the rupee; and the refining of gold for the public should, if necessary, be undertaken at the mints (para. 67). I look on this as one of the most important of the Committee's proposals. It means that while the mints must necessarily remain closed to free coinage of silver, such automatic coinage is established for gold, and will materially facilitate its import into India.

In view of the present shortage of silver, the old notification guaranteeing free exchange of rupees for sovereigns and half sovereigns, which has been in practical abeyance for some years owing to the scarcity value of gold, should be withdrawn, though the Government will naturally continue to exchange one form of coin for another when it can conveniently do this (para. 68).

The Committee recommend (para. 70) that the present restriction on the import of silver should be done away with; otherwise, when the bullion value of the rupee is close on its exchange value, the silver required for non-monetary purposes is likely, in spite of any legal prohibition, to be obtained by melting, thus increasing the necessity for fresh silver purchases by the Secretary of State. As a corollary to this they propose (para. 71) that a special import duty of 4 annas per oz. on silver, introduced for fiscal reasons in 1910, should be withdrawn, as it hampers imports, and provokes melting when the bullion value of the rupee is near its exchange value. Both these proposals have already been carried out, and the prohibition of the melting of coin has been withdrawn.

Restrictions on the export of silver must be maintained so long as the bullion and exchange values of the rupee are close together (para. 72).

The present arrangements under which the Secretary of State purchases silver for coinage should continue (para. 74).

The Committee next discuss future policy in regard to the paper currency reserve. As we have seen, the necessities of the war period brought about a very large increase in the invested portion, which was gradually raised by a series of temporary enactments that will presently expire from 14 crores (ten in Indian securities and four in British) to a maximum of 120 (twenty Indian and one hundred British); but this last limit has not been fully worked up to. At the end of March, 1919, against a gross circulation of about 153½ crores, the metallic holding was nearly 55 crores, or below 36 per cent., and the investments totalled about 98½ crores. At the end of November the position was better; the gross circulation was nearly 180 crores, against which about 80 crores or over 44½ per cent. were held in metal, 17 crores in Indian securities and 82½ in British. At the end of February it was somewhat better still; against a gross circulation of 183 crores, 85 crores, or nearly 46½ per cent., were held in metal, about 15½ crores in Indian securities, and 82½ as before in British; the latter holding being almost entirely in Treasury Bills. The Committee note with approval (para. 75) the large expansion of the note issue, but justly observe that its popularity can only continue so long as its convertibility is placed beyond possible doubt. They agree with the Chamberlain Commission (paras. 77–79) that the old system of limiting the

fiduciary portion of the paper currency reserve to a rigidly fixed amount is undesirable, and should be superseded by a percentage ratio on the circulation, which they propose to fix by laying down that the metallic portion shall amount to at least 40 per cent. of the total note circulation, leaving a maximum of 60 per cent. available for investment. They admit, however, otherwise their proposal would be rash in view of recent difficulties, that the statutory minimum for the metallic portion should in practice be materially exceeded, especially at the commencement of each busy season. Of the fiduciary portion they recommend that up to 20 crores should be tenable in Indian securities, and the balance in those of Great Britain and of other Governments within the Empire, while of this latter amount all but 10 crores should be in securities of not more than one year's maturity. On the figures given by the Committee for November 1919 this would have involved a maximum holding at that time of 20 crores of Indian and nearly 88 crores of British and Imperial securities. They recommend, however, that in view of the present difficulties power should be taken, in the legislation that will be required, to retain for a limited period the total permissible maximum of 120 crores for investment given by the temporary enactment above referred to. Personally, I should like to see the metallic holding of the paper currency reserve fixed normally, at any rate for a considerable period, at not less than 50 per cent. of the note circulation.

The Committee also recommend (para. 80) that a further special issue of notes up to 5 crores, to meet seasonal demands for additional currency, should be made on the security of short-term commercial bills of exchange endorsed by the Presidency Banks (hereafter the Central Bank of India), these notes being issued as an advance to the banks, carrying interest at not less than 8 per cent.

The note circulation being in rupees, the composition of the paper currency reserve is rightly described in terms of rupees also, and for this purpose its gold holdings and sterling investments have hitherto been taken at 15 rupees to the pound. The change in the gold value of the rupee will necessitate (leaving out of account the temporary depreciation of sterling as compared with gold) the revaluation of these at Rs. 10 to the pound, involving on present figures a deficiency of about 38 crores to be made good to the paper currency reserve. It is recognised that this large deficiency, which in time will be more than covered by savings in home charges brought about by the increased value of the rupee, cannot be made good at once, but it is proposed that this should be done gradually against the savings obtained under home charges (para. 79).

The location of the paper currency reserve should normally be in India; but, as hitherto, silver under purchase or in course of shipment should be treated as part of the reserve, and some of the gold may be held in London, either as awaiting subsequent shipment to India or as being presently required for silver purchase (para. 81).

As soon as circumstances permit, the old facilities for the encashment of notes outside currency centres should be restored, though these should continue to be a matter of grace and not of right (para. 82). The temporary restrictions, previously referred to, on the transit of silver from these centres are obviously intended by the Committee to be withdrawn as soon as possible.

As regards the gold standard reserve, the Committee (para. 83) endorse the Chamberlain Commission's view that in present circumstances it should continue to receive the whole of the profits on coinage. They review (para. 84) the composition of the reserve at the time they reported, which then amounted to about £37,500,000, practically the whole of which was invested—mainly in British Treasury Bills and Exchequer Bonds maturing in 1920 and 1921, and in National War Bonds redeemable in 1922. They refer to the Chamberlain Commission's proposal that half the total reserve should be kept in actual gold, and admit in principle that there should be a considerable proportion of gold holding; but they think that in present circumstances such gold as can be obtained for the Government of India should be preferably held in the paper currency reserve, and that it will suffice to lay down that the gold standard reserve investments should be in British and Imperial securities, having a maturity of not more than twelve months. In my humble opinion this decision is not altogether satisfactory, having regard to the fact that, under the Committee's proposals, the metallic portion of the paper currency reserve (gold plus silver) may run down to only 40 per cent. of the note circulation; and I think it is desirable, for the purpose of stimulating public confidence, that a material portion of the gold standard reserve should be in gold. The Committee recognise the value of this confidence asset when they go

on to suggest (para. 85) that a portion, not exceeding one half, of the gold held in the reserve should be located in India and set apart for export purposes; but the suggestion seems to lack practical value, in view of the Committee's finding in their previous paragraph. I may explain, however, that final orders have yet to be passed on the proposals relating to the paper currency and gold standard reserves, and on certain cognate matters.

I am sorry to have to close my analysis of the Committee's proposals on a note of difference, but this does not in the least detract from the admiration I feel for the report as a whole. And it is a matter for peculiar satisfaction that though the Committee's members must have approached the grave problems with which they had to deal from diverse standpoints, they came to almost complete unanimity on the many important issues before them. The only dissent, indeed, is a minority report by my genial friend, Mr. Dadiba Merwanjee Dalal, of Bombay, in which he proposes to keep the old ratio of 1*s.* 4*d.* per rupee, both for exchange and internal circulation purposes, and to effect this by giving full freedom for the melting and export of rupees and the import of gold. He proposes to meet high silver prices by abstaining from the issue of rupees of the existing pattern so long as the American price per silver ounce is above 92 cents, and to fill the gap by the issue of a 2-rupee coin of reduced fineness and a similarly reduced 8-anna silver piece. He also recommends that reverse councils should be sold at 1*s.* $3\frac{29}{32}$*d.* It is difficult to take this scheme seriously, as it is absolutely open to the Secretary of State's criticisms that it would involve depreciation of the coinage, drain on silver stocks which must entail grave risk of inconvertibility, a demand for gold which would impose a heavy strain on the world's stock, an immediate crash in exchange through the operation of the reverse councils proposals, and inflation of prices.

And now I shall relieve you by bringing my remarks to a close. I fear I have trespassed over much on your attention, but I have found it impossible to bring into shorter compass the developments and vicissitudes of a long period, and the grave strain which unforeseen happenings during a prolonged world-war brought on India's currency system. Fate may yet have other and great vicissitudes in store for us, but I think we may regard the success with which past difficulties have been met as a satisfactory omen for the future.

DISCUSSION.

THE CHAIRMAN (Lord Chalmers) said he thought no one could have traversed so much ground so ably, and yet so succinctly, as Sir William Meyer had done. He had expressed a fear, towards the close of his paper, that he had trespassed overmuch on their time, but he could assure him that that was not the case. It had been a great relief to him (the Chairman) to find that the paper was not a polemical one; it was enough to be in the chair without being in the dock as well. From 1913 to 1918, as Finance Member of the Governor-General's Council, Sir William Meyer had had to deal with a situation fraught with difficulties, the quality and quantity of which were unparalleled, and that applied also to all those who were responsible for finance in other parts of the world. Finance was always the handmaiden of government, but in times of crisis and panic it becomes its scapegoat as well, and there were many astute people who found in finance a ready means of carrying on an offensive defence of their own shortcomings. He ventured to prophesy that when people came to look back on the unparalleled period through which they had passed during the war, the verdict of economic history would be a kindly one; and those who, like their lecturer that afternoon, had borne the burden and the heat of the day, would find in that verdict a generous, if tardy, meed of praise. Sir William Meyer's last words were: "Fate may yet have other and great vicissitudes in store for us, but I think we may regard the success with which past difficulties have been met as a satisfactory omen for the future." That applied not only to Sir William, but also to the four Currency Commissions which had reported from 1893 to 1919, with all of which he (the Chairman) had had the privilege of being associated. Those four Commissions had at least one thing in common—they were actuated by the desire to regard the very difficult problems submitted to them in the light of the interests of the people of India. From his acquaintance with those Commissions he would say of those who sat on them, in the words of Sir Henry Fowler, "They were all members for India." The last Commission, over which Sir Henry Babington Smith presided, had not been backward in following that ideal. That Commission had been at one with Sir William Meyer in declining to listen to any counsels of despair, and in not giving the faintest countenance to any steps which led towards inconvertibility. It was with the greatest reluctance that they had departed from the principle of linking the rupee to sterling. However, they had departed from it, and in his judgment rightly. They had advocated as the basis of Indian currency not the sterling pound—the "Bradbury"—but the golden sovereign, and they had arrived at that conclusion—which was not an easy or agreeable one—solely in the interests of India as a whole, and feeling that that was the policy along which India's interests would lie in the future. They had been deeply influenced by the fact that in advocating

a gold basis for the currency of India they were doing their best to safeguard the interests of the helpless masses in that country.

LORD BALFOUR OF BURLEIGH, K.T., P.C., G.C.M.G., G.C.V.O., said he had been much interested in Sir William Meyer's paper, having to a certain extent tried to study the problems with which it dealt. He represented the Cabinet on the 1899 Commission, and was glad to think that the foundations then laid had been justified by the course of events from that year until the outbreak of the war. The change brought about by the war was very extraordinary. In 1899 the problem was how to keep the rupee up to 1*s.* 4*d.*; the problem now was how to keep it below 2*s.* 8*d.*, rather a change of circumstances. He thought they all owed a great debt to Sir William Meyer for his interesting and exhaustive survey of the history and development of Indian currency. The paper proved that, whatever might be said by some people, the policy of the Government of Great Britain towards the people of India had been guided by honesty and straightforwardness. They had tried, and he thought successfully, to maintain the confidence of the people of India. He cordially endorsed the principle that in the future, as in the past, they must take care that the convertibility of the note issue in India should be beyond doubt or suspicion. He had been glad to hear of the prosperity of India's trade, which he thought was attributable to the way in which they had supported the exchange in that country. For the trouble they had taken in that direction they had, he thought, reaped their reward by the noble way in which their Indian fellow-members of the Empire had stood by them recently in the cause for which they had been fighting. The loyalty of the people of India, differing as they did in race, religion and circumstances, had deeply impressed this country with the value of justice and fairness. He was glad to be present to give his humble testimony as to the way in which many who had no personal interest in the matter were yet deeply concerned with the welfare of their Indian brothers.

MR. MORETON FREWEN said he was glad to join with Lord Balfour of Burleigh in his appreciation of Sir William Meyer's paper. He regarded it as a classic on the subject, and as likely to be of great historical value. He was one of those who viewed the whole experiment of a gold standard for India with the utmost dismay, and he thought the great majority of thinkers were coming round to that opinion. He had just crossed from San Francisco to New York. Although the conditions in America pointed to a most remarkable prosperity, the appalling dangers of the European situation connected with sterling exchange had almost dried up the fount of charity. Since the commencement of the fatal experiment of 1893 this country had lost to India over three hundred millions sterling of gold. If they had that gold here to-day in order to assist reconstruction, the problem would be enormously simplified. If the immense series of experiments, to which every fresh Treasury hand who went to India added something new, was to be continued, it was certain that as exchange conditions became more normal they would lose to India at least forty million sovereigns a year. The three hundred million people in India had been, according to the admission of every Finance Member, perfectly satisfied with silver, and the idea of giving to them the gold which was needed so urgently in this country was altogether wrong. There was not enough gold for the purpose, and in attempting to carry out that policy Great Britain had lost her own gold standard permanently. What chance had we or France or Italy of resuming specie payments if this hæmorrhage continued to Asia? For hundreds of years the East, with its eight hundred millions of people, had had favourable trade balances against the West, and they had always drawn those balances three-quarters in silver and one-quarter in gold. The hundred per cent. rise in gold prices in the last six years meant that where India drew one ounce of gold before, she would now draw two, and the same with silver, so that favourable trade balances would require twice as much specie as before to liquidate them. There was no gold to do it with. The currency had been so tinkered with that there was no longer even sufficient silver to pay the trade balances owing to Asia. He had studied the question in India and outside for thirty-five years, and he had no hesitation in saying that the old honest currency system of India—the freely-minted silver rupee—which had been destroyed, was a most admirable system. Before 1893 the rupee was melted down, and the currency was thereby automatically contracted and a rise of prices guarded against. As Goschen said at the time, no matter what happened prices in India remained stable. That splendid condition of price stability had been destroyed in order to give India a currency system she disliked, and which must involve the ruin of our finance. Several references had been made in the paper to the assurance of the Chamberlain Commission that India should have the kind of currency she preferred, no matter what its cost to the outer world. Did anyone believe that three hundred millions of poor ignorant people in India were clamouring for a "gold standard"? They had always desired to get silver, and had never taken gold except to hoard it, nor ever would. At the time of MacKinley's election as President a conference of representatives of Great Britain, France, and the United States was held at the Foreign Office, and the Americans offered, together with France, to open their mints to the free coinage of silver, the Indian mints to re-open. All that this country had done was to refer the matter to the then Viceroy of India, Lord Elgin, who, knowing nothing about currency

questions, was permitted to negative this splendid offer. If the Republican Party got into power in America—and he thought they would—they were likely to make a proposal to the European Governments that they should open free mints for silver, and thus stabilise the exchanges. The currency system brought into use by the Fowler Commission was merely the miserable old "Bland Act" repealed in the United States in 1893. Before any settlement could be made in the Indian exchange problem the bad work done since the date of that Commission would have to be reversed. To illustrate the importance of allowing free coinage to the natives who had got hoards of silver, he said that at Allahabad during the famine of 1897, the headman of two villages situated in the worst part of the famine district came in with two thousand tolas of silver bullion and ornaments in order to buy food for the villagers. He ought to have got, and would have got had the mints been open, two thousand rupees for this silver; but the best price he could get was six hundred rupees from a local shroff. By how much was the death-rate added to?

Mr. George Miller (Chartered Bank of India, Australia, and China) said that he was in Bombay at the outbreak of the war, and could thus bear witness to the strenuous times Sir William had to go through. He had had many difficult problems to face, and many anxious moments during the whole period of his office. It was stated in the paper that reverse councils had been so largely applied for in India that they constituted a drain on the reserves. Was there any necessity for offering reverse councils at all? So far as he knew, they seemed to be largely availed of by speculators. The rates at which the Government had been obliged to sell were in many cases *3d.* to *4d.* above the current market quotations.
